Auto Register Duplication	Allows the Fitter to automatically duplicate registers within a LAB that contains empty logic cells. This option does not alter the functionality of the design. The Compiler ignores the **Auto Register Duplication** option if you select **OFF** as the setting for the **Logic Cell Insertion -- Logic Duplication** logic option. Turning on this option allows the **Logic Cell Insertion -- Logic Duplication** logic option to improve a design's routability, but can make formal verification of a design more difficult. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.

Table 53. Advanced Fitter Settings (3 of 8)

Option	Description
Enable Auto-Pipelining	Turns on the auto-pipelining and latency-insensitive false path feature. Use this setting in conjunction with the **Maximum Additional Pipelining** and optional **Additional Pipelining Group** assignments in the Assignment Editor to automatically add pipeline registers at the locations you specify. *Note:* Only available for Stratix 10 and Agilex 7 devices.
Enable Bus-Hold Circuitry	Enables bus-hold circuitry during device operation. When this option is **On**, a pin retains its last logic level when it is not driven, and does not go to a high impedance logic level. Do not use this option with the **Weak Pull-Up Resistor** option because doing so enables the location of the Critical Chain Viewer from the Fast option. The Compiler ignores this option if you apply it to anything other than a pin.
Enable Critical Chain Viewer	Enables critical chain visualization in the Fast Forward Timing Closure Recommendations report for Stratix 10 and Agilex 7 devices.
Equivalent RAM and MLAB Paused Read Capabilities	Specifies whether RAMs implemented in MLAB cells must have equivalent paused read capabilities as RAMs implemented in block RAM. Pausing a read is the ability to keep around the last read value when reading is disabled. Allowing differences in paused read capabilities provides the Fitter more flexibility in implementing RAMs using MLAB cells. To allow the Fitter the most flexibility in deciding which RAMs are implemented using MLAB cells, set this option to **Don't Care**. The following options are available: • **Don't Care**—the Fitter can convert RAMs to MLAB cells, even if they do not have equivalent paused read capabilities to a block RAM implementation. The Fitter generates an information message about RAMs with different paused read capabilities. • **Care**—the Fitter does not convert RAMs to MLAB cells unless they have the equivalent paused read capabilities to a block RAM implementation.

continued...

Option	Description
Equivalent RAM and MLAB Power Up	Specifies whether RAMs implemented in MLAB cells must have equivalent power-up conditions as RAMs implemented in block RAM. Power-up conditions occur when the device powers-up or globally resets. Allowing non-equivalent power-up conditions provides the Fitter more flexibility in implementing RAMs using MLAB cells. To allow the Fitter the most flexibility in deciding which RAMs are implemented using MLAB cells, set this option to **Auto** or **Don't Care**. The following options are available: • **Auto**—the Fitter may convert RAMs to MLAB cells, even if the MLAB cells lack equivalent power-up conditions to a block RAM implementation. The Fitter also outputs a warning message about RAMs with non-equivalent power up conditions. • **Don't Care**—the same behavior as **Auto** applies, but the message is an information message. • **Care**—the Fitter does not convert RAMs to MLAB cells unless they have equivalent power up conditions to a block RAM implementation.
Final Placement Optimizations	Specifies whether the Fitter performs final placement optimizations. Performing final placement optimizations may improve timing and routability, but may also require longer compilation time.
Fitter Aggressive Routability Optimizations	Specifies whether the Fitter aggressively optimizes for routability. Performing aggressive routability optimizations may decrease design speed, but may also reduce routing wire usage and routing time. The **Automatically** setting allows the Fitter to decide whether aggressive routability is beneficial.

Table 54. Advanced Fitter Settings (4 of 8)

Option	Description
Fitter Effort	Specifies the level of physical synthesis optimization during fitting: • **Auto**—adjusts the Fitter optimization effort to minimize compilation time, while still achieving the design timing requirements. Use the **Auto Fit Effort Desired Slack Margin** option to apply sufficient optimization effort to achieve additional timing margin. • **Standard**—uses maximum effort regardless of the design's requirements, leading to higher compilation time and more margin on easier designs. For difficult designs, **Auto** and **Standard** both use maximum effort. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
Fitter Initial Placement Seed	Specifies the seed for the current design. The value can be any non-negative integer value. By default, the Fitter uses a seed of 1. The Fitter uses the seed as the initial placement configuration when optimizing design placement to meet timing requirements f_{MAX}. Because each different seed value results in a somewhat different fit, you can try several different seeds to attempt to obtain superior fitting results. The seeds that lead to the best fits for a design may change if the design changes. Also, changing the seed may or may not result in a better fit. Therefore, specify a seed only if the Fitter is not meeting timing requirements by a small amount. *Note:* You can also use the Design Space Explorer II (DSEII) to sweep complex flow parameters, including the seed, in the Quartus Prime software to optimize design performance.
Logic Cell Insertion	Allows the Fitter to automatically insert buffer logic cells between two nodes without altering the functionality of the design. The Compiler creates buffer logic cells from unused logic cells in the device. This option also allows the Fitter to duplicate a logic cell within a LAB when there are unused logic cells available in a LAB. Using this option can increase compilation time. The default setting of **Auto** allows these operations to run when the design requires them to fit the design. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
MLAB Add Timing Constraints for Mixed-Port Feed-Through Mode Setting Don't Care	Specifies whether the Timing Analyzer evaluates timing constraints between the write and the read operations of the MLAB memory block. Performing a write and read operation simultaneously at the same address might result in metastability issues because no timing constraints between those operations exist by default. Turning on this option introduces timing constraints between the write and read operations on the MLAB memory block and

continued...

Option	Description
	thereby avoids metastability issues. However, turning on this option degrades the performance of the MLAB memory blocks. If your design does not perform write and read operations simultaneously at the same address, you do not need to set this option.
Number of Example Nodes Reported in Fitter Messages	Allows you to specify the maximum number of example nodes Fitter messages should display.

Table 55. Advanced Fitter Settings (5 of 8)

Option	Description
Optimize Design for Metastability	This setting improves the reliability of the design by increasing its Mean Time Between Failures (MTBF). When you enable this setting, the Fitter increases the output setup slacks of synchronizer registers in the design. This slack can exponentially increase the design MTBF. This option only applies when using the Timing Analyzer for timing-driven compilation. Use the Timing Analyzer `report_metastability` command to review the synchronizers detected in your design and to produce MTBF estimates.
Optimize Hold Timing	Directs the Fitter to optimize hold time within a device to meet timing requirements and assignments. The following settings are available: • **I/O Paths and Minimum TPD Paths—**directs the Fitter to meet the following timing requirements and assignments: — t_H from I/O pins to registers. — Minimum t_{CO} from registers to I/O pins. — Minimum t_{PD} from I/O pins or registers to I/O pins or registers. • **All Paths**—directs the Fitter to meet the following timing requirements and assignments: — t_H from I/O pins to registers. — Minimum t_{CO} from registers to I/O pins. — Minimum t_{PD} from I/O pins or registers to I/O pins or registers. When you disable the **Optimize Timing** logic option, the **Optimize Hold Timing** option is not available.
Optimize IOC Register Placement for Timing	Specifies whether the Fitter optimizes I/O pin timing by automatically packing registers into I/Os to minimize delays. • **Normal**—the Fitter opportunistically packs registers into I/Os that should improve I/O timing. • **Pack All I/O Registers**— the Fitter aggressively packs any registers connected to input, output, or output enable pins into I/Os, unless prevented by your constraints or other legality restrictions. • **Off**—performs no periphery to core optimization.
Optimize Multi-Corner Timing	Directs the Fitter to consider all timing corners during optimization to meet timing requirements. These timing delay corners include both fast-corner timing and slow-corner timing. By default, this option is **On**, and the Fitter optimizes designs considering multi-corner delays in addition to slow-corner delays. When this option is **Off**, the Fitter optimizes designs considering only slow-corner delays from the slow-corner timing model (slowest manufactured device for a given speed grade, operating in low-voltage conditions). Turning this option **On** typically creates a more robust design implementation across process, temperature, and voltage variations. When you turn **Off** the **Optimize Timing** option, the **Optimize Multi-Corner Timing** option is not available.
Optimize Timing	Specifies whether the Fitter optimizes to meet the maximum delay timing requirements (for example, clock cycle time). By default, this option is set to **Normal compilation**. Turning this option **Off** helps fit designs that with extremely high interconnect requirements. Turning this option **Off** can also reduce compilation time at the expense of timing performance (because the Fitter ignores the design's timing requirements). If this option is **Off**, other Fitter timing optimization options have no effect (such as **Optimize Hold Timing**).

Table 56. Advanced Fitter Settings (6 of 8)

Option	Description
Periphery to Core Placement and Routing Optimization	Specifies whether the Fitter should perform targeted placement and routing optimization on direct connections between periphery logic and registers in the FPGA core. The following options are available: • **Auto**—the Fitter automatically identifies transfers with tight timing windows, places the core registers, and routes all connections to or from the periphery. The Fitter performs these placement and routing decisions before the rest of core placement and routing. This sequence ensures that these timing-critical connections meet timing, and also avoids routing congestion. • **On**— the Fitter optimizes all transfers between the periphery and core registers, regardless of timing requirements. Do not set this option to **On** globally. Instead, use the Assignment Editor to assign optimization to a targeted set of nodes or entities. • **Off**—the Fitter performs no periphery to core optimization. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
Physical Placement Effort	Controls how much effort the Fitter spends during advanced physical placement optimization. **High** and **Maximum** effort settings result in additional compile time to further optimization the placement solution.
Placement Effort Multiplier	Specifies the relative time the Fitter spends in placement. The default value is 1.0, and legal values must be greater than 0. Specifying a floating-point number allows you to control the placement effort. A higher value increases CPU time but may improve placement quality. For example, a value of '4' increases fitting time by approximately 2 to 4 times but may increase quality.
Power Optimization During Fitting	Directs the Fitter to perform optimizations targeted at reducing the total power devices consume. The available settings for power-optimized fitting are: • **Off**—performs no power optimizations. • **Normal compilation**—performs power optimizations that are unlikely to adversely affect compilation time or design performance. • **Extra effort**—performs additional power optimizations that might affect design performance or result in longer compilation time.

Table 57. Advanced Fitter Settings (7 of 8)

Option	Description
Programmable Power Maximum High-Speed Fraction of Used LAB Tiles	Sets the upper limit on the fraction of the high-speed LAB tiles. Legal values must be between 0.0 and 1.0. The default value is 1.0. A value of 1.0 means that there is no restriction on the number of high-speed tiles, and the Fitter uses the minimum number needed to meet the timing requirements of your design. Specifying a value lower than 1.0 might degrade timing quality, because some timing critical resources might be forced into low-power mode.
Programmable Power Technology Optimization	Controls how the Fitter configures tiles to operate in high-speed mode or low-power mode. The following options are available: • **Automatic**—specifies that the Fitter minimizes power without sacrificing timing performance. • **Minimize Power Only**—specifies that the Fitter sets the maximum number of tiles to operate in low-power mode. • **Force All Used Tiles to High Speed**—specifies that the Fitter sets all used tiles to operate in high-speed mode. • **Force All Tiles with Failing Timing Paths to High Speed**—sets all failing paths to high-speed mode. For designs that meet timing, the behavior of this setting is similar to the **Automatic** setting. For designs that fail timing, all paths with negative slack are put in high-speed mode. This mode likely does not increase the speed of the design, and it may increase static power consumption. This mode may assist in determining which logic paths need to be re-designed to close timing.

continued...

Option	Description
	Note: Only available for Arria 10 and Cyclone 10 GX devices.
Router Timing Optimization Level	Controls how aggressively the router tries to meet timing requirements. Setting this option to **Maximum** can increase design speed slightly, at the cost of increased compile time. Setting this option to **Minimum** can reduce compile time, at the cost of slightly reduced design speed. The default value is **Normal**.

Table 58. Advanced Fitter Settings (8 of 8)

Option	Description
Synchronizer Identification	Specifies how the Compiler identifies synchronization register chain registers for metastability analysis. A synchronization register chain is a sequence of registers with the same clock with no fan-out in between, which is driven by a pin or logic from another clock domain. The following options are available: • **Off**—the Timing Analyzer does not identify the specified registers, or the registers within the specified entity, as synchronization registers. • **Auto**—the Timing Analyzer identifies valid synchronization registers that are part of a chain with more than one register that contains no combinational logic. Use the **Auto** setting to generate a report of possible synchronization chains in your design. • **Forced if Asynchronous**—the Timing Analyzer identifies synchronization register chains if the software detects an asynchronous signal transfer, even if there is combinational logic or only one register in the chain. • **Forced**—the Timing Analyzer identifies the specified register, or all registers within the specified entity, as synchronizers. Do not apply the **Forced** option to the entire design as it identifies all registers in the design as synchronizers. The Fitter optimizes the registers that it identifies as synchronizers for improved Mean Time Between Failure (MTBF), provided that you enable **Optimize Design for Metastability**. If a synchronization register chain is identified with the **Forced** or **Forced if Asynchronous** option, then the Timing Analyzer reports the metastability MTBF for the chain when it meets the design timing requirements.
Treat Bidirectional Pin as Output Pin	Specifies that the Fitter treats the bidirectional pin as an output pin, meaning that the input path feeds back from the output path.
Use Checkered Pattern as uninitialized RAM Content	Loads a checkered pattern as initial RAM content into all RAM blocks without specified RAM content that supports content initialization. Turning on this option does not affect simulation, which may cause on-chip behavior to differ from simulation results.
Weak Pull-Up Resistor	Enables the weak pull-up resistor when the device is operating in user mode. This option pulls a high-impedance bus signal to VCC. Do not enable this option simultaneously with the **Enable Bus-Hold Circuitry** option. The Fitter ignores this option if you apply to anything other than a pin.

Other Assignments

```
set_global_assignment –name ERROR_ON_INVALID_ENTITY_NAME
```

The software ignores `.qsf` and `.qip` assignments where the entity field is not a name that exists in the design and generates a warning. If you set `ERROR_ON_INVALID_ENTITY_NAME` to `ON`, the software generates these warnings as errors.

1.19. Design Compilation Revision History

This document has the following revision history.

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Added Precompiled Component (PCC) flow to *Compilation Flows*. • Updated images and added information about the "RTL Analysis Debug Mode" in *Analysis & Elaboration Flow*. • Updated the images and enhanced the information in *Using the Node Finder*. • Revised the information in *Fast Forward Details Report*. • Added *Precompiled Component (PCC) Generation Flow*.
2023.12.04	23.4	• Enhanced the *Compiler Optimization Modes* topic with additional information. • Updated file properties image in *Registering the SDC-on-RTL SDC File* and *Using SDC-on-RTL Features*. • In *Design Synthesis*, added information about converting `.bdf` to `.v` or `.vhd` file, and updated the image. • Renamed *DNI-Based Compilation Flow* as *Analysis & Elaboration Flow*. • Added information about Early Timing Analysis flow in *Compilation Overview*. • Reorganized *DNI-Based Analysis & Elaboration Flow* and *Early Timing Analysis After Design Synthesis* sections. • Renamed *DNI-Based Node Finder* as *Using the Node Finder* • Added an image for Property Viewer showing constraints in *Exploring the RTL Analyzer*. • Reorganized most of the topics under *Design Netlist Infrastructure* and moved them into relevant sections of this chapter. • Removed the term "DNI" in the title and content of the following topics: — *Use Case Examples* — *Scripting Routine Tasks Using Tcl Commands* — *Traversing the Design Netlist Using Tcl Commands* • Revised the information and image in *Design Synthesis*. • Added information about SDC-on-RTL file in *Running Synthesis*. • Revised the image, added a note for "Parameter Settings by Entity Instance" and added information about SDC constraints in *Viewing Synthesis Reports*. • Revised the existing information in *Concurrent Analysis During Synthesis or Fitting*. • Added a note about version compatibility in *Importing a Version-Compatible Compilation Database*, and *Exporting a Design Partition*. • Renamed the topic *Compilation Monitoring* as *Compilation Monitoring Mode* and revised the topic entirely. • Revised *Enable Intermediate Fitter Snapshots* with additional information. • Added *Preparing for Design Synthesis*. • Removed *Early Timing Analysis After Design Synthesis* and merged its information with *Post-Synthesis Static Timing Analysis (STA)*.
2023.10.02	23.3	• Enhanced the instructions and removed "Beta" in *Design Netlist Infrastructure* and *Exploring the RTL Analyzer*. • Made minor revisions to the description in *Object Set Console*. • Updated "Viewing Unbundled Instances" section in *Bundled Instances*. • Completely revised the instructions in *Early Timing Analysis After Design Synthesis*. • Made minor updates to *Synopsys* Design Constraint (SDC) on RTL*. • Completely updated "RTL Analyzer" section and added additional information about Constraints viewer in *Inspecting SDC-on-RTL Constraints*.

continued...

Document Version	Quartus Prime Version	Changes
		• Added the following topics — *Entity-Based SDC-on-RTL* — *Using SDC-on-RTL Features* — *DNI-Based Node Finder* • Updated the commands and replaced SYN_SDC_FILE with SDC_FILE `-read_during_post_syn_and_not_post_fit_timing_analysis` in *Post-Synthesis Static Timing Analysis (STA)*. • Replaced SYN_SDC_FILE in *Types of SDC Files Used in the Quartus Prime Software*. • Reorganized the topics in the *Design Compilation* chapter per the DNI-based compilation dashboard. • Updated the compilation dashboard image in the following topics: — *Using the Compilation Dashboard* — *Concurrent Analysis During Synthesis or Fitting* — *Step 1: Run Register Retiming* — *Step 3: Run Fast Forward Compile* — *Fast Forward Compile By Hierarchy* • Added description for "Number of Congested Nets" column in *Global Router Congestion Hotspot Summary Report*. • Revised the descriptions of optimization modes in *Compiler Optimization Modes*. • Removed the topic *Connectivity Tracer*. • Updated the "Hierarchical Project Structure" image along with its description in *Compilation Hierarchy*.
2023.04.03	23.1	• In *Design Netlist Infrastructure (Beta)*, updated the images and added a note about the incompatibilities between classic and DNI compilation flows. • In *Exploring the RTL Analyzer (Beta)*, updated the images and improved their clarity. • Enhanced the *Sweep Hints Viewer* topic with additional information and images. • Enhanced the *Inspecting SDC-on-RTL Constraints* topic with additional information about Object Constraints viewer. • Revised the *Object Set Console* topic entirely. • Revised the *Auto-hide Unconnected Pins* topic entirely. • Renamed the topic *Early Timing Analysis (Beta)* to *Early Timing Analysis After Design Synthesis (Beta)* and revised the information and images. • Enhanced *Applying the SDC-on-RTL Constraints* with additional information about the Constraint Propagation Report. • Updated the images and revised some instructions in *Post-Synthesis Static Timing Analysis (STA)*. • Updated the product family name to "Intel Agilex 7." • Revised description of Fitter (Finalize) command for latest physical synthesis optimizations.
2022.12.19	22.4	• Added *Filtering*. • Added *Expand Connections*. • Revised *Object Set Console* with additional information and images.
2022.09.26	22.3	• Added *Early Timing Analysis (Beta)*. • Added *Synopsys* Design Constraint (SDC) on RTL*. • Added *Registering the SDC-on-RTL SDC File*. • Added *Applying the SDC-on-RTL Constraints*. • Added *Managing SDC-on-RTL Constraints*. • Added *Writing Constraints in SDC-on-RTL SDC Files*. • Added *Post-synthesis Static Timing Analysis (STA)*.

continued...

Document Version	Quartus Prime Version	Changes
		• Added *Types of SDC Files Used in the Quartus Prime Software*. • Added *Object Set Console*. • Added *Module Interfaces*. • Added *Connectivity Tracer*. • Added *DNI Use Case Examples*. • Added *Scripting Routine Tasks Using DNI Tcl Commands*. • Added *Traversing the DNI Netlist Using Tcl Commands*. • Added *Viewing Synthesis Dynamic Report*. • Split the topic *Instances Bundling and Auto-hiding Unconnected Pins* into separate topics *Bundled Instances* and *Auto-hide Unconnected Pins*. • Revised *Bundled Instances* with additional information. • Revised images in *Exploring the RTL Analyzer* and *Design Netlist Infrastructure (DNI)*.
2022.06.21	22.2	• Added *Design Netlist Infrastructure (DNI)*. • Added *Exploring the RTL Analyzer*. • Added *Module Interfaces*. • Added *Instances Bundling and Auto-hiding Unconnected Pins*.
2022.03.28	22.1	• Added *Compilation Monitoring*. • Added *Global Router Congestion Hotspot Summary Report*. • Revised *Full Compilation Flow*. • Added *Full Compilation Flow with Temporary Optimization Mode*.
2022.01.27	21.4	• Revised *Compiler Optimization Modes* topic to provide implication details of various modes.
2021.11.03	21.3	• Made a minor correction in *Reusing a Design Partition* step 4. • Removed the callouts from *Creating a Design Partition* topic.
2021.10.04	21.3	• Added *Preserving Signals for Monitoring and Debugging* topic. • Revised *Preserving Registers During Synthesis* topic for new debugging signal preservation assignments. • Revised *Viewing Synthesis Reports* topic to include new warnings summary reports. • Revised *Optimization Modes* topic to include new optimization modes. • Revised *VHDL Synthesis* Support to include VHDL 2019 support. • Revised *VHDL Input Settings (Settings Dialog Box)* topic to include VHDL 2019 support. • Added *VHDL-2019 Conditional Analysis* topic.
2021.06.21	21.2	• Added *Version-Compatible Compilation Database Support* table.
2021.03.29	21.1	• Added Check Unregistered Ports report to "Validating Timing Constraints with Snapshot Viewer" topic. • Updated "Running Snapshot Viewer" topic to indicate the reports that are available after the final snapshot. • Removed reference to Rapid Recompile from "Enable Intermediate Filter Snapshots". Support for Rapid Recompile has been removed. • Added information to "Using the Compilation Dashboard" to indicate that an interrupted compilation flow can be resumed.
2020.12.14	20.3	• Corrected typo in "Automatic Gated Clock Conversion" topic.
2020.11.09	20.3	• Added new "Integrating Other EDA Tools" topic. • Added new "Generating a VQM Netlist for Other EDA Tools" topic.
2020.09.28	20.3	• Added references to ECO Compilation Flow. • Removed references to deprecated Early Place Compiler flow.

continued...

Document Version	Quartus Prime Version	Changes
2020.05.08	20.1	• Added note about programming file differences between versions to "Compilation Overview" topic.
2020.04.13	20.1	• Added new "Fast Forward Compile by Hierarchy" topic. • Added new assignment to "Fitter Settings Reference" topic.. • Updated "Verilog and SystemVerilog Synthesis Support" topic for SystemVerilog 2012 support. • Added programming file generation support for Intel Agilex devices. • Added "Analyzing with the Snapshot Viewer" topic. • Added "Running the Snapshot Viewer" topic. • Added "Analyzing Failing Paths with Snapshot Viewer" topic. • Added "Analyzing Clocking with Snapshot Viewer" topic. • Added "Analyzing High Fan-Out Nets with Snapshot Viewer" topic. • Added "Analyzing Constraints with Snapshot Viewer" topic. • Added "Analyzing Congestion with Snapshot Viewer" topic. • Removed *Early Place Flow* • Removed *Synthesis Reports* figure and table. • Removed *Heat-Map in Global Signal Visualization Report* figure • Changed sentence in *Fast Forward Compilation* to *The Fitter automatically retimes registers across RAM and DSP blocks* from *The Fitter does not automatically retime registers across RAM and DSP blocks*. • Added more **Preservation Level** information to *Design Partition* table.
2019.10.20	19.3	• Added "Automatic Gated Clock Conversion" topic. • Updated "Fractal Synthesis Optimization" and "Enabling or Disabling Fractal Synthesis" topics for automated fractal synthesis for small multipliers.
2019.09.30	19.3	• Added support for Intel Agilex devices throughout. • Added "Global Signal Visualization Report" topic. • Added "Global Router Wire Utilization Map" topic. • Added "Fast Preserve Option" topic. • Reordering of some topics to match design flow.
2019.07.02	19.1	• Made minor changes in "Fractal Synthesis Optimization" topic. • Added a note in step 3a of "Running Synthesis" about enabling fractal synthesis project-wide. • Added details about synthesis of PRESERVE_FANOUT_FREE_NODE to "Partial Reconfiguration Design Guidelines." • Corrected typo in "Step 3: Run Fast Forward Compile and Hyper-Retiming." • Removed "Enabling Timing-Driven Synthesis" topic.
2019.04.01	19.1	• In "Running Synthesis", removed a step about enabling fractal synthesis project-wide. • Updated the "Fractal Synthesis Optimization" topic to describe signed multiplication feature that is now supported by multiplier regularization and arithmetic packing algorithms.
2019.01.03	18.1.0	• Added snapshot description to "Compilation Overview" and linked to content from "Exporting a Design Partition" and "Exporting a Version-Compatible Compilation Database."

continued...

Document Version	Quartus Prime Version	Changes
2018.10.19	18.1	• Described dependency of Rapid Recompile on Enable Intermediate Fitter Snapshots option.
2018.09.24	18.1	• Described option to enable or disable intermediate Fitter snapshots and updated descriptions of compilation flows and dashboard accordingly. • Added "Exporting Compilation Results section and subtopics." • Described migration of full chip database in "Exporting a Version-Compatible Compilation Database" topic. • Described automated `.qdb` partition export in "Exporting a Design Partition" topic. • Described viewing QDB file metadata in "Viewing Quartus Database File Information." • Added "Fractal Synthesis Optimization" topic and updated "Running Synthesis" topic steps for new option. • Described new Compiler Optimization Modes and described notice that appears for extended optimization modes added via `.qsf`. • Described new Global Signal Visualization Report. • Added "Factors Affecting Compilation Results" topic. • Added "Using the Compilation Dashboard" topic. • Added description of Enable Auto-Pipelining setting. • Added description of Enable Formal Verification Support to "Advanced Synthesis Settings." • Added description of Report PR Initial Values as Errors option to "Advanced Synthesis Settings." • Added description of Size of the Latch Report option to "Advanced Synthesis Settings." • Added description of Size of the PR Initial Conditions Report option to "Advanced Synthesis Settings." • Added description of Advanced Physical Synthesis option to "Fitter Settings Reference." • Added description of Allow DSP Retiming option to "Fitter Settings Reference." • Added description of Allow Early Global Retiming in the Fitter option to "Fitter Settings Reference." • Added description of Allow Hyper-Aware Register Chain Area Optimizations in the Fitter option to "Fitter Settings Reference." • Added description of Allow RAM Retiming option to "Fitter Settings Reference." • Added description of Number of Example Nodes Reported in Fitter Messages option to "Fitter Settings Reference." • Added description of Physical Placement Effort option to "Fitter Settings Reference." • Added description of Use Checkered Pattern as uninitialized RAM Content option to "Fitter Settings Reference." • Updated description of Safe State Machine option for Auto setting. • Removed support for Ignore ROW GLOBAL Buffers option. • Removed support for Ignore CARRY Buffers option. • Removed support for Ignore CASCADE Buffers option.
2018.05.07	18.0	• Updated Optimization Modes topic to add Compile Time (Aggressive). • Relocated concurrent analysis content from the *Early Place Flow* topic to a new *Concurrent Analysis During Synthesis or Fitting* topic. • Rapid Recompile now supports Stratix 10 devices. • Enhanced description of Retime Stage Reports. • Enhanced description of Retime Stage to include classic register retiming.

Table 59. Document Revision History

Date	Version	Changes
2017.11.06	17.1.0	• Added support for Stratix 10 Hyper-Aware design flow, Hyper-Retiming, Fast Forward compilation, and Fast Forward Viewer. • Added Advanced HyperFlex Settings topic. • Added Retiming Restrictions and Workarounds topic. • Added statement about Fast Forward compilation support for retiming across RAM and DSP blocks. • Added Concurrent Analysis topic. • Added Analyzing Fitter Snapshots topic. • Added Compilation Dashboard Early Place stage control image. • Added Running late_place After Early Place topic. • Updated for latest Intel naming conventions.
2017.05.08	17.0.0	• Added reference to initial compilation support for Cyclone 10 GX devices. • Described concurrent analysis following Early Place. • Updated Compilation Dashboard images for Timing Analyzer, Report, Setting, and Concurrent Analysis controls. • Updated description for Auto DSP Block Replacement in Advanced Synthesis Settings. • Updated Advanced Fitter Settings for Allow Register Retiming, and for removal of obsolete SSN Optimization option. • Added Prevent Register Retiming topic. • Added Preserve Registers During Synthesis topic. • Removed limitation for **Safe State Machine** logic option. • Added references to Partial Reconfiguration and Block-Based Design Flows.
2016.10.31	16.1.0	• Implemented Intel re-branding. • Described Compiler snapshots and added Analyzing Snapshot Timing topic. • Updated project directory structure diagram. • Described new Fitter stage menu commands and reports. • Added description of Early Place Flow, Implement Flow, and Finalize Flow. • Added description of Incremental Optimization in the Fitter. • Reorganized order of topics in chapter. • Removed deprecated **Per-Stage Compilation (Beta)** Compilation Flow.
2016.05.03	16.0.0	• Added description of Fitter Plan, Place and Route stages, reporting, and optimization. • Added **Per-Stage Compilation (Beta)** Compilation Flow • Added Compilation Dashboard information. • Removed support for **Safe State Machine** logic option. Encode safe states in RTL. • Added Generating Dynamic Synthesis Reports topic. • Updated Quartus project directory structure.
2015.11.02	15.1.0	• First version of document.

2. Reducing Compilation Time

You can employ various techniques to reduce the time required for synthesis and fitting in the Quartus Prime Compiler.

2.1. Factors Affecting Compilation Results

Almost any change to the following project settings, hardware, or software can impact the results from one compilation to the next.

- Project Files—changes to project settings (`.qsf`, `quartus2.ini`), design files, and timing constraints (`.sdc`) can change the results.
- Any setting that changes the number of processors during compilation can impact compilation results.
- Hardware—CPU architecture, not including hard disk or memory size differences. Windows XP x32 results are not identical to Windows XP x64 results. Linux x86 results is not identical to Linux x86_64.
- Quartus Prime Software Version—including build number and installed interim updates. Click **Help > About** to obtain this information.
- Operating System—Windows or Linux operating system, excluding version updates. For example, Windows XP, Windows Vista, and Windows 7 results are identical. Similarly, Linux RHEL, CentOS 4, and CentOS 5 results are identical.

2.2. Strategies to Reduce the Overall Compilation Time

You can use the following strategies to reduce the overall time required to compile your design:

- Running the ECO Compilation Flow on page 187
- Enabling Multi-Processor Compilation on page 188
- Using Block-Based Compilation on page 191

2.2.1. Running the ECO Compilation Flow

The Quartus Prime Pro Edition software supports last-minute, targeted design changes (also known as engineering change orders (ECOs)), even after you fully compile the design. ECOs typically occur during the design verification stage. Refer to the *Quartus Prime Pro Edition User Guide: Design Optimization* for details.

Related Information

Intel Quartus Prime Pro Edition User Guide: Design Optimization

2.2.2. Enabling Multi-Processor Compilation

The compiler can detect and use multiple processors to reduce total compilation time. By default, the compiler uses the setting specified under **Parallel Compilation** in the **Processing** page of the **Options** dialog box. To reserve some processors for other tasks, specify the maximum number of processors the software must use.

Using multiple processor cores provides several benefits for improving software performance as follows:

- **Faster execution**: The Quartus Prime software can support up to 24 processors, which means the software can run algorithms in parallel. This technique reduces the compilation time by up to 10% on systems with two processing cores and up to 20% on systems with four processors. When running timing analysis independently, two processors reduce the timing analysis time by an average of 10%. This reduction reaches an average of 15% when using four processors.
- **Increased throughput**: With more processing cores, systems can execute multiple tasks simultaneously, which means the software can handle more requests simultaneously. The Quartus Prime software may not necessarily utilize all the processors specified during compilation. The software has the flexibility to scale its usage to use up to the maximum number of processors specified. To achieve the highest possible throughput, Intel recommends using a system equipped with at least four processing cores, allowing the software to take full advantage of the available computing resources.
- **Reduced latency**: With multiple processing cores, the software responds more quickly to your requests, improving the overall experience. The software never uses more than the specified number of processors, so you can work on other tasks in parallel without slowing down your computer.
- **More efficient resource utilization**: By distributing tasks across multiple processor cores, the Quartus Prime software can use available resources more efficiently, reducing the overall cost of running the software.

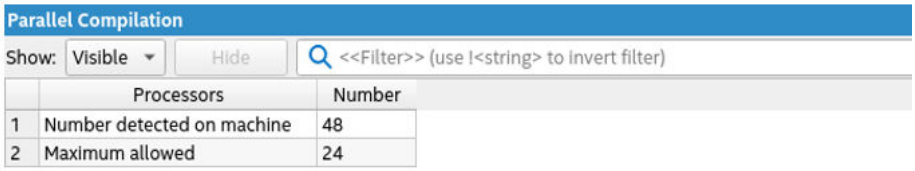
The use of multiple processors does not affect the quality of the fit. The fit is the same and deterministic for a given Fitter seed and given **Maximum processors allowed** setting on a specific design. This remains true regardless of the target system and the number of available processors. Different **Maximum processors allowed** specifications produces different results of the same quality. The impact is similar to changing the Fitter seed setting.

To enable multiprocessor compilation, follow these steps:

1. Open or create an Quartus Prime project.
2. Click **Assignments ➤ Settings ➤ Compilation Process Settings**.
3. Under **Parallel compilation**, specify options for the number of processors the compiler uses.

   View the number of processors detected on your system in the Parallel Compilation report after compilation ends.

Figure 139. Parallel Compilation Report



The following is the QSF setting that controls the maximum number of processors. If this line is in your project's QSF file, do not specify it again.

```
set_global_assignment -name NUM_PARALLEL_PROCESSORS <value>
```

In this case, <*value*> is an integer from 1 to 24.

If you want the Quartus Prime software to detect the number of processors and use all the processors for the compilation, include the following Tcl command in your script:

```
set_global_assignment -name NUM_PARALLEL_PROCESSORS ALL
```

Note:
- Using multiple processor cores can help the Quartus Prime software run faster, handle more tasks, and provide a better user experience. However, other factors, such as memory bandwidth or I/O bottlenecks, may limit performance. So, you must consider specific requirements and constraints of each project when deciding how many processor cores to use.
- The compiler detects Intel Hyper-Threading® Technology (Intel HT Technology) as a single processor. If your system includes a single processor with Intel HT Technology, set the number of processors to one. Set the number of processors according to the number of physical processors in your system,

The following are other factors that affect performance in the Quartus Prime software:

2.2.2.1. Processor Base Clock Frequency

Using faster processor cores provides several advantages, including:

- **Faster execution**: With faster processor cores, the Quartus Prime software can execute tasks more quickly, which can improve overall system performance and reduce the time required to complete complex calculations, algorithms, and data processing tasks.
- **Improved multitasking**: Faster processor cores can improve the ability of the Quartus Prime software to handle multiple tasks simultaneously, reducing the risk of system slowdowns when running several algorithms simultaneously.
- **Quicker start-up and shutdown times**: Faster processors can reduce the time required for the Quartus Prime software to open and close side applications, such as Timing Analyzer, Platform Designer, and more. This can improve your productivity and reduce downtime.

For shortest compile times, you should choose processors with the highest base clock frequency available and prioritizing higher CPU frequency over having more cores. While additional cores can be beneficial for tasks that are highly parallelizable,

focusing on higher frequency ensures faster execution of individual threads, leading to improved responsiveness and overall performance of the Quartus Prime Pro Edition software.

2.2.2.2. Random Access Memory (RAM)

There are several advantages to having more RAM, including:

- **Improved performance**: With more RAM, the Quartus Prime software can store more data in memory, thereby reducing the need for the system to access the slower hard drive for frequently used data. This can result in faster application launch times, quicker compilation times, and faster overall system performance.
- **Better multitasking**: More RAM allows a computer to handle more processes simultaneously without slowing down. This is particularly important when you want to simultaneously use the Quartus Prime software and other applications or programs.
- **Improved productivity**: More RAM can improve the productivity of the Quartus Prime software by reducing the time required for complex tasks, such as compilation.

Note:

- The Quartus Prime Pro Edition Software and Device Support Release Notes provides valuable information regarding the software's system requirements and recommended configurations. Consult the release notes to determine the minimum required RAM for your computer to optimize performance.
- To fully leverage the system's capabilities, Intel recommends utilizing the maximum number of DIMM slots available. This configuration provides ample memory capacity and bandwidth, allowing for efficient handling of complex designs.

In addition, by tracking the virtual memory utilization, you can identify potential performance issues and optimize your system for better efficiency when using the Quartus Prime Pro Edition software. Consult the peak virtual memory from a previous compile by viewing the flow report or the Flow Elapsed Time report category from the compilation report in the compilation dashboard.

The following example Flow Elapsed Time report shows the peak virtual memory:

Figure 140. Flow Elapsed Time Report

Flow Elapsed Time

Show: Visible | Hide | <<Filter>> (use !<string> to invert filter)

	Module Name	Elapsed Time	Peak Virtual Memory
1	Synthesis	00:00:38	1513 MB
2	Fitter	00:08:46	13709 MB
3	Timing Analyzer	00:00:35	3749 MB
4	Total	00:09:59	--

Running numerous processes concurrently can consume a significant amount of memory resources and potentially lead to performance issues. so Intel recommends considering the peak virtual memory used for each project and avoiding multiple compilations that exceed the available memory capacity of your computer. This helps prevent congestion in the RAM memory.

Overall, by maximizing the RAM capacity, you can ensure smooth and optimal performance and better multitasking to enhance productivity during resource-intensive tasks, enabling faster processing, reduced latency, and improved productivity of the Quartus Prime Pro Edition software.

2.2.2.3. Storage

Storage can be a factor that limits performance in the Quartus Prime software since the Quartus Prime Pro Edition software reads source files and constraints and reads/writes to the database. For best results, Intel recommends the following to ensure consistent system performance:

- Downloading all the necessary files from the network.
- Completing the compilation process using local disks.
- Uploading the finished results back to the network by avoiding storage latency (varies on each system).

Intel recommends prioritizing the selection of the fastest affordable SSD drive for your storage needs. Opting for an SSD over traditional disk drives significantly enhances load and save times and greatly improves overall operating system performance. SSDs offer superior speed and responsiveness, making them an excellent choice to ensure the best performance experience when using the Quartus Prime Pro Edition software.

2.2.3. Using Block-Based Compilation

During the design process, when making minor modifications to a design, recompiling the entire design can result in longer compilation times than anticipated. This is because every time you recompile a design following a change, the compiler may apply global optimizations to enhance resource utilization and timing performance, thus extending the compilation time. By employing a block-based flow in the Quartus Prime Pro Edition software, you can isolate functional blocks that meet placement and timing requirements from others still undergoing change and optimization. By isolating functional blocks into partitions, the results and performance of unaltered logic within a design are maintained so you can apply optimization techniques to selected areas and only compile those areas. This approach can significantly diminish design compilation time, enabling several iterations per day and facilitating more efficient achievement of timing closure.

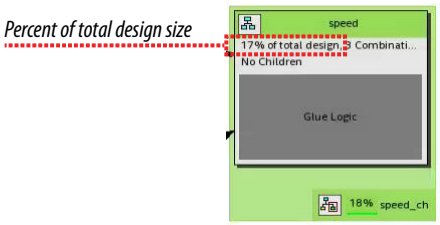
When using block-based compilation, you can enable the **Fast Preserve** option, which masks the partition netlist during the fitter initialization to use only the logic that interfaces with the rest of the design present at the partition boundary during compilation. By implementing this approach, the time required for the compiler to perform synthesis, place, route, and partition is effectively reduced. Consequently, the overall compilation process becomes more efficient, enabling faster generation of the necessary configurations for the partition. This reduction in compilation time allows for quicker iterations and facilitates the timely completion of the design implementation phase.

To create partitions dividing functional blocks:

1. In the Design Partition Planner, identify blocks of a size suitable for partitioning.

   A partition generally represents roughly 15 to 20% of the total design size. You should use the information area below the bar at the top of each entity.

Figure 141. Entity representation in the Design Partition Planner



2. Extract and collapse entities as necessary to achieve stand-alone blocks.
3. For each entity of the desired size containing related blocks of logic, right-click the entity and click **Create Design Partition** to place that entity in its own partition.

   The goal is to achieve partitions containing related blocks of logic.
4. To enable the **Fast Preserve** option that simplifies the logic of the preserved partition to only interface logic during compilation, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Incremental Compile ➤ Fast Preserve**.

Intel recommends consulting the *Quartus Prime Pro Edition User Guide: Block-Based Design* to gain in-depth knowledge about block-based designs. This guide serves as a comprehensive resource that provides detailed information, instructions, and explanations related to the Quartus Prime Pro Edition software.

2.3. Reducing Synthesis Time and Synthesis Netlist Optimization Time

You can reduce synthesis time without affecting the Fitter time by reducing your use of netlist optimizations. For tips on reducing synthesis time when using third-party EDA synthesis tools, refer to your synthesis software's documentation.

2.3.1. Settings to Reduce Synthesis Time and Synthesis Netlist Optimization Time

Synthesis netlist and physical synthesis optimization settings can significantly increase the overall compilation time for large designs. Refer to Analysis and Synthesis messages to determine the length of optimization time.

If your design already meets performance requirements without synthesis netlist or physical synthesis optimizations, turn off these options to reduce compilation time. If you require synthesis netlist optimizations to meet performance, optimize partitions of your design hierarchy separately to reduce the overall time spent in Analysis and Synthesis.

2.3.2. Use Appropriate Coding Style to Reduce Synthesis Time

Your HDL coding style can also affect the synthesis time. For example, if you want to infer RAM blocks from your code, you must follow the guidelines for inferring RAMs. If RAM blocks are not inferred properly, the software implements those blocks as registers.

If you are trying to infer a large memory block, the software consumes more resources on the FPGA. This can cause routing congestion and increases compilation time significantly. If you see high routing utilization in certain blocks, review the code for such blocks.

2.4. Reducing Placement Time

The time required to place a design depends on two factors:

- The number of ways the logic in your design can be placed in the device.
- The settings that control the amount of effort required to find a good placement.

You can reduce the placement time by changing the settings for the placement algorithm. If you have enabled a higher performance effort compiler optimization mode, you can try reducing the effort setting and observe how it trades off runtime and quality of results (QoR).

You can also observe the placement of major logic blocks in your design (over multiple compiles) to see whether the major blocks tend to get placed in the same places in the floorplan between the compiles. Suppose major blocks get placed in different places in some compiles. If those placements correlate with good QoR, create Logic Lock regions to ensure the blocks are placed in those regions with good QoR, which should help reduce compile time.

Sometimes there is a trade-off between placement time and routing time. Routing time can increase if the placer does not run long enough to find a good placement. When you reduce placement time, ensure that it does not increase routing time and negate the overall time reduction.

2.4.1. Placement Effort Multiplier Settings

The **Placement Effort Multiplier** option controls how much time the Fitter spends in placement. Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)** and specify a value for Placement Effort Multiplier.

The default value is 1.0, and valid values are greater than 0. Specifying a floating-point number allows you to control the placement effort. A lower value decreases the CPU time but may reduce placement quality. You cannot directly increase the **Placement Effort Multiplier** to a value greater than 1.0. Use predefined Optimization Mode settings to increase placement effort for improved timing optimization.

2.5. Reducing Routing Time

The routing time is usually not a significant amount of the compilation time. The time required to route a design depends on three factors: the device architecture, the placement of your design in the device, and the connectivity between different parts of your design.

If your design requires a long time to route, perform one or more of the following actions:

- Check for routing congestion.
- Turn off **Fitter Aggressive Routability Optimization**.

2.5.1. Identifying Routing Congestion with the Chip Planner

To identify areas of routing congestion in your design:

1. Click **Tools ➤ Chip Planner**.
2. To view the routing congestion in the Chip Planner, double-click the **Report Routing Utilization** command in the **Tasks** list.
3. Click **Preview** in the **Report Routing Utilization** dialog box to preview the default congestion display.
4. Change the **Routing utilization type** to display congestion for specific resources. The default display uses dark blue for 0% congestion and red for 100%.
5. Adjust the slider for **Threshold percentage** to change the congestion threshold level.

The Quartus Prime compilation messages contain information about average and peak interconnect usage. Peak interconnect usage over 75%, or average interconnect usage over 60% indicate possible difficulties fitting your design. Similarly, peak interconnect usage over 90%, or average interconnect usage over 75%, indicate a high chance of not getting a valid fit.

2.5.1.1. Areas with Routing Congestion

Even if average congestion is not high, the design may have areas where congestion is high in a specific type of routing. You can use the Chip Planner to identify areas of high congestion for specific interconnect types.

- You can change the connections in your design to reduce routing congestion
- If the area with routing congestion is in a Logic Lock region or between Logic Lock regions, change or remove the Logic Lock regions and recompile your design.
  - If the routing time remains the same, the time is a characteristic of your design and the placement
  - If the routing time decreases, consider changing the size, location, or contents of Logic Lock regions to reduce congestion and decrease routing time.

Related Information

Intel Quartus Prime Pro Edition User Guide: Design Optimization

2.5.1.2. Congestion due to HDL Coding style

Sometimes, routing congestion may be a result of the HDL coding style used in your design. After identifying congested areas using the Chip Planner, review the HDL code for the blocks placed in those areas to determine whether you can reduce interconnect usage by code changes.

2.6. Reducing Static Timing Analysis Time

If you are performing timing-driven synthesis, the Quartus Prime software runs the Timing Analyzer during Analysis and Synthesis.

The Quartus Prime Fitter also runs the Timing Analyzer during placement and routing. If there are incorrect constraints in the Synopsys Design Constraints File (`.sdc`), the Quartus Prime software may spend unnecessary time processing constraints several times.

- If you do not specify false paths and multicycle paths in your design, the Timing Analyzer may analyze paths that are not relevant to your design.
- If you redefine constraints in the `.sdc` files, the Timing Analyzer may spend additional time processing them. To avoid this situation, look for indications that Synopsis design constraints are being redefined in the compilation messages, and update the `.sdc` file.
- Ensure that you provide the correct timing constraints to your design, because the software cannot assume design intent, such as which paths to consider as false paths or multicycle paths. When you specify these assignments correctly, the Timing Analyzer skips analysis for those paths, and the Fitter does not spend additional time optimizing those paths.

2.7. Setting Process Priority

It might be necessary to reduce the computing resources allocated to the compilation at the expense of increased compilation time. It can be convenient to reduce the resource allocation to the compilation with single processor machines if you must run other tasks at the same time.

2.8. Reducing Compilation Time Revision History

Document Version	Quartus Prime Version	Changes
2023.12.04	23.4	• Enhanced the information in *Reducing Placement Time*. • Revised the information in *Placement Effort Multiplier Settings*.
2023.06.26	23.2	• Revised the information in *Enabling Multi-Processor Compilation* and *Using Block-Based Compilation*. • Added the following new topics: — *Processor Base Clock Frequency* — *Random Access Memory (RAM)* — *Storage*
2022.09.26	22.3	• Updated *Enabling Multi-Processor Compilation* topic for processor limit increase from 16 to 24.
2022.01.27	21.4	• Removed references to obsolete Compilation Time Advisor.
2021.11.03	21.3	• Made minor update to step 1 in *Using Block-Based Compilation*.
2021.10.04	21.3	• Removed "Disabling the Register Power-up Initialization".

continued...

Document Version	Quartus Prime Version	Changes
2021.03.29	21.1	• Support for Rapid Recompile has been removed, resulting in the following changes: — Removed reference to Rapid Recompile from "Strategies to Reduce the Overall Compilation Time". — Removed "Running Rapid Recompile" topic.
2020.09.28	20.3	• Added reference to ECO Compilation flow.
2019.11.11	19.3	• Added support for Fast Preserve option to "Using Block-Based Compilation" topic.
2019.09.30	19.3	• Added support for Intel Agilex devices throughout.
2019.07.02	19.1	Added the *Using the No-Register Initialization Flow* topic.
2018.10.19	18.1	• Described dependency of Rapid Recompile on Enable Intermediate Fitter Snapshots option.
2017.11.06	17.1	• Added topic: Using Block-Based Compilation.

Date	Version	Changes
2017.05.08	17.0.0	• Clarified impact of multiprocessor compilation on fit quality. • Removed reference to deprecated Fitter Effort Logic Option. • Removed section: *Preserving Routing with Incremental Compilation*.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2016.05.02	16.0.0	• Corrected typo in Using Parallel Compilation with Multiple Processors. • Removed information about deprecated physical synthesis options.
2015.11.02	15.1.0	Changed instances of *Quartus II* to *Quartus Prime*.
2014.12.15	14.1.0	• Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Synthesis Optimizations to Compiler Settings. • Added information about Rapid Recompile feature.
2014.08.18	14.0a10.0	Added restriction about smart compilation in Arria 10 devices.
June 2014	14.0.0	Updated format.
May 2013	13.0.0	Removed the “Limit to One Fitting Attempt”, “Using Early Timing Estimation”, “Final Placement Optimizations”, and “Using Rapid Recompile” sections. Updated “Placement Effort Multiplier Settings” section. Updated “Identifying Routing Congestion in the Chip Planner” section. General editorial changes throughout the chapter.
June 2012	12.0.0	Removed survey link.
November 2011	11.0.1	Template update.
May 2011	11.0.0	• Updated “Using Parallel Compilation with Multiple Processors”. • Updated “Identifying Routing Congestion in the Chip Planner”. • General editorial changes throughout the chapter.
December 2010	10.1.0	• Template update. • Added details about peak and average interconnect usage. • Added new section “Reducing Static Timing Analysis Time”. • Minor changes throughout chapter.
July 2010	10.0.0	Initial release.

3. Quartus Prime Pro Edition User Guide Design Compilation Archives

Related Information

- Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Quartus Prime Pro Edition software, including managing Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

Design Optimization

Updated for Quartus® Prime Design Suite: **24.1**

This document is part of a collection - Quartus® Prime Pro Edition User Guides - Combined PDF link

Answers to Top FAQs:

Contents

1. Design Optimization Overview

In the early stages of FPGA design development, you typically focus on meeting your timing requirement, resource usage, and power consumption goals. After meeting these basic goals, you can focus on optimizing performance.

Optimization of FPGA design performance requires a multi-dimensional approach to reduce resource use, critical path delays, power consumption, and runtime. The Quartus® Prime software provides various tools and techniques for performance optimization.

This chapter provides an overview of the initial techniques and settings in the Quartus Prime software that you can use to optimize your design results and achieve the highest performance in Intel FPGAs.

Related Information

Quartus Prime Pro Edition User Guide: Design Compilation

1.1. Initial FPGA Device Considerations

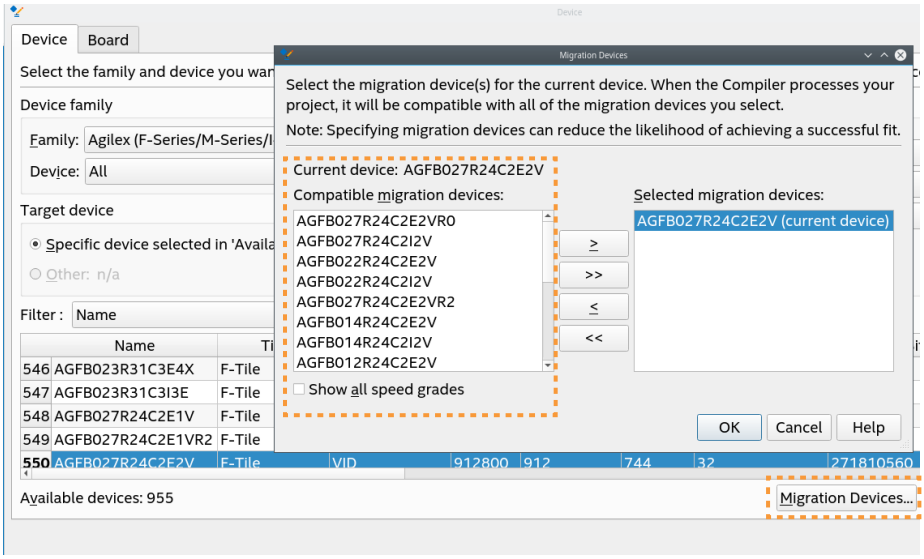
All Intel® FPGAs have a unique timing model that describes the delay information between all physical elements in the device, such as combinational adaptive logic modules, memory blocks, interconnects, and registers. The delay models comprise all valid combinations of operating condition delays for the target FPGA. The Timing Analyzer references these delay models in calculating performance during timing analysis. The device size and package determine pin-out and the resource availability. When selecting your target Intel FPGA device for your design, you must consider the performance specifications and resources available in the device meet the needs of your design.

1.1.1. Device Migration Considerations

If you anticipate that you might later migrate your design to a different target device later in the design cycle (for example, a larger or faster device), you must plan for this migration from the beginning of cycle. Planning for migration early helps you to minimize the complex design changes that you must make later to accommodate the new device.

When choosing a target FPGA device in the **Device** dialog box, you can click the **Migration Devices** button to view a list of all compatible devices.

Figure 1. Devices Available for Migration from Selected Device



Related Information

Migration Devices Dialog Box
In *Quartus Prime Help*

1.2. Initial Compiler Settings

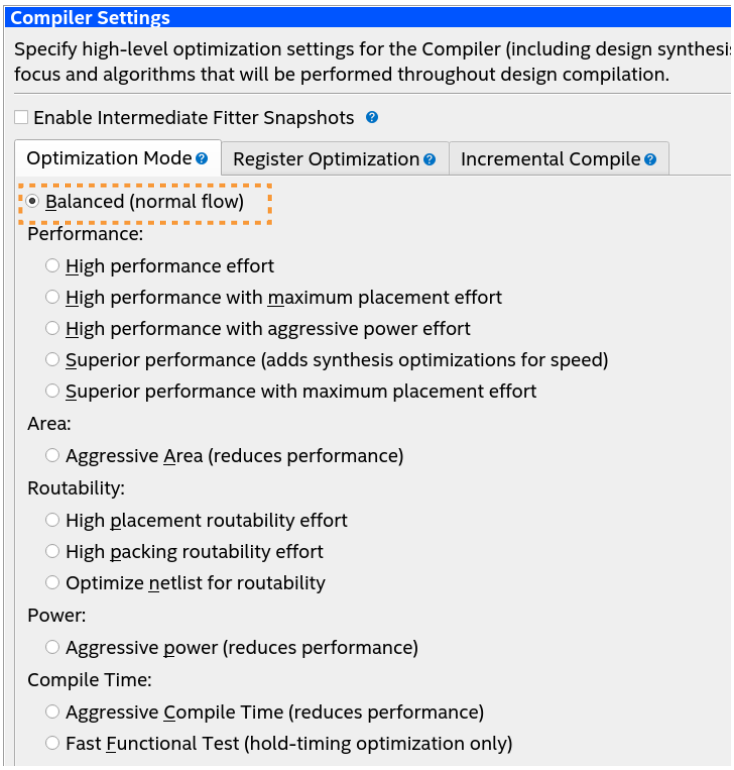
Your design compilation results can vary significantly, depending on the initial assignments and settings that you choose prior to compiling. The Quartus Prime software initial settings for compilation are set to provide a balanced trade-off between the time required for compilation, the device resource utilization, and the design timing performance.

You can easily adjust this trade-off to focus the Compiler's effort more on shortening the total compile time, reducing device resource utilization, or maximizing timing performance.

The initial FPGA device selection and Compiler settings have a very significant impact on design performance and optimization. You should also consider the following guidelines for specifying initial settings before compiling your design for the first time in the Quartus Prime software.

Figure 2. Compiler Optimization Mode Settings

Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Optimization Mode** to adjust the Compiler's effort on **Performance**, **Area**, **Routability**, or **Compile Time**.



1.2.1. Initial I/O Assignment Guidelines

The I/O standard and drive strength requirements that you specify for your design affect the I/O timing. Follow these guidelines when specifying initial I/O assignments:

- When specifying I/O assignments, specify an accurate I/O timing delay for timing analysis and Fitter optimizations.
- If the PCB layout does not indicate pin locations, then leave the pin locations unconstrained. This technique allows the Compiler to search for the best layout. Otherwise, make pin assignments to constrain the compilation appropriately.

Related Information

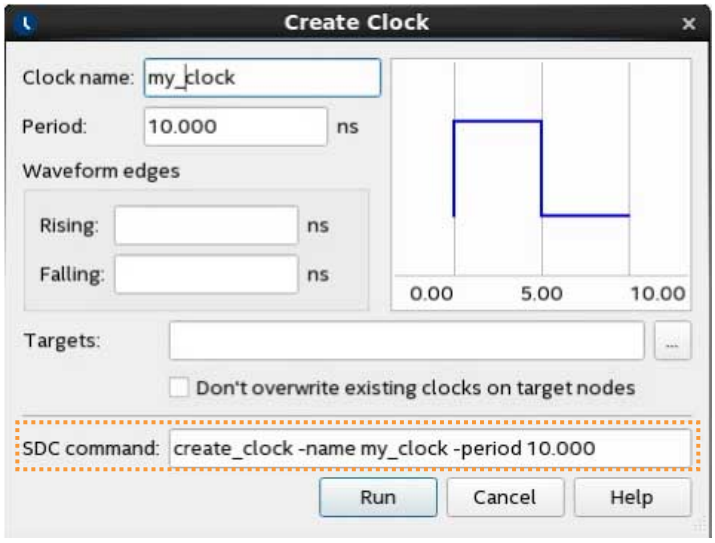
Quartus Prime Pro Edition User Guide: Design Constraints
In *Quartus Prime Pro Edition User Guide: Design Constraints*

1.2.2. Initial Timing Constraint Guidelines

Before running initial compilation or timing analysis, specify realistic timing requirements. Specifying more stringent timing requirements than the design requires causes the Compiler to expend effort to increase performance at the expense of resource usage, power utilization, or compilation time.

Click **Tools ➤ Timing Analyzer** then click the Constraints menu to enter constraints in the GUI, such as defining the clock signals. Alternatively, you can specify timing constraints directly in an `.sdc` file.

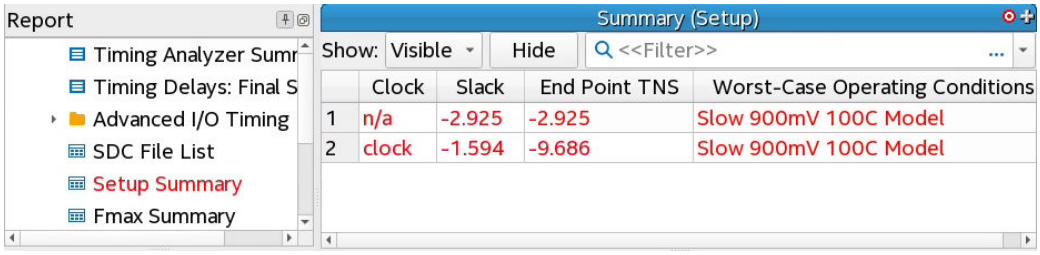
Figure 3. Create Clock Dialog Defines Clock Constraints



Specifying realistic and comprehensive timing requirements up front helps the Compiler to achieve the best results for the following reasons:

- Comprehensive timing assignments enable the Compiler to work hardest to optimize the performance of the timing-critical parts of the design. This optimization can also save area or power utilization in non-critical parts of the design.
- Enables physical synthesis optimizations based on the comprehensive timing requirements.

Figure 4. Timing Analyzer Shows Failing Paths in Red



Following compilation and timing analysis, the Compilation Report reports whether the design meets the timing requirements. You can then use the Quartus Prime Timing Analyzer to fine tune constraints and report detailed information about all timing paths.

1.3. Optimization Trade-Offs and Limitations

Design optimization requires balancing the trade-offs between device performance, resource usage, power utilization, and compilation time. Your application of project settings and constraints determines the balance of these factors in meeting your design goals. When you want to increase optimization of one type, you can consider the trade-offs that might limit that optimization.

Table 1. Design Optimization Trade-Off Examples

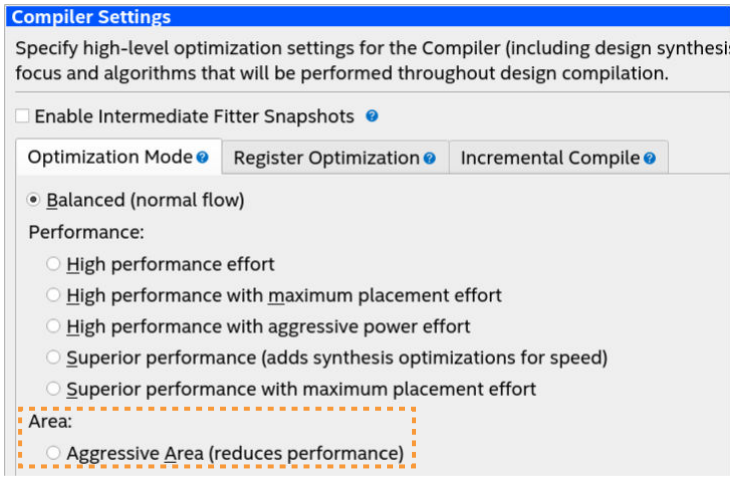
Trade-off	Comments
Resource usage and critical path timing.	Certain techniques (such as logic duplication) can improve timing performance at the cost of increased area.
Power requirements can result in area and timing trade-offs.	For example, reducing the number of available high-speed tiles, or attempting to shorten high-power nets at the expense of critical path nets.
System cost and time-to-market considerations can affect the choice of device.	For example, a device with a higher speed grade or more clock networks can facilitate timing closure at the expense of higher power consumption and system cost.

Finally, constraints that are too stringent can produce a situation with no possible solution for the selected device. If the Fitter cannot resolve a design due to resource limitations, timing constraints, or power constraints, consider rewriting parts of the HDL code.

1.3.1. Area Reduction Trade-Offs

By default, the Quartus Prime Fitter might physically spread a design over the entire device to meet the set timing constraints. If you prefer to optimize your design to use the smallest area, you can change this behavior by selecting **Aggressive Area** for the Compiler **Optimization Mode**. If you require reduced area, you can enable certain physical synthesis options to modify your netlist to create a more area-efficient implementation, but at the cost of increased runtime and decreased performance.

Figure 5. Optimize for Area



Related Information

- Area Optimization on page 47
- Netlist Optimizations and Physical Synthesis on page 40

1.3.2. Critical Path Delay Reduction Trade-Offs

To meet complex timing requirements involving multiple clocks, routing resources, and area constraints, the Quartus Prime software offers a close interaction between synthesis, floorplan editing, place-and-route, and timing analysis processes.

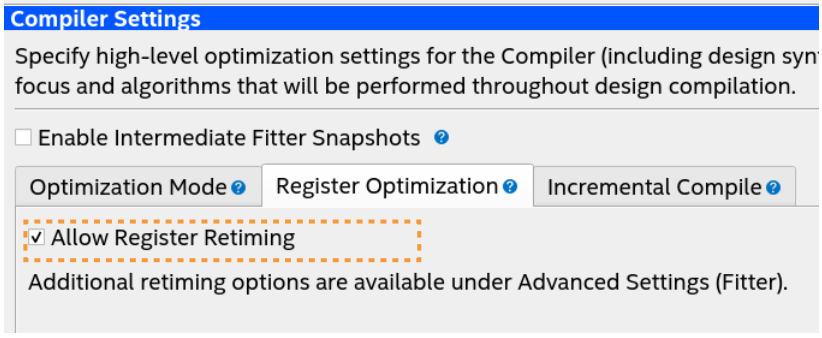
By default, the Quartus Prime Fitter works to meet the timing requirements, and reduces fitting effort once the requirements are met. Therefore, specifying realistic constraints is crucial for achieving timing closure.

Under-constraining your design can lead to sub-optimal results. Over-constraining your design might cause the Fitter to over-optimize non-critical paths at the expense of true critical paths. Over-constraining the design may also increase area and compilation time.

When designs have very high resource usage, the Fitter may struggle to find a legal placement. In such circumstances, the Fitter automatically modifies settings to try to trade off performance for area.

In high-density FPGAs, routing accounts for a major part of critical path timing. Because of this, duplicating or retiming logic can allow the Fitter to reduce delay on critical paths. The Quartus Prime software offers push-button netlist optimizations and physical synthesis options that can improve design performance at the expense of considerable increases of compilation time and area.

Figure 6. Register Optimization



Turn on only those options that help you keep reasonable compilation times and resource usage. Alternately, you can modify the HDL to manually duplicate or adjust the timing logic.

Related Information

Optimize Critical Paths on page 65

1.3.3. Power Consumption Reduction Trade-Offs

The Quartus Prime software has features that help reduce design power consumption. The power optimization options control the power-driven compilation settings for Synthesis and the Fitter. You can adjust these settings

1.3.4. Compilation Time Trade-Offs

Many Fitter settings influence compilation time. Most of the default settings in the Quartus Prime software are set for reduced compilation time. You can modify these settings for your project requirements to trade-off longer compilation time for increased performance.

The Quartus Prime software supports parallel compilation in computers with multiple processors. This technique can reduce compilation times by up to 15%.

1.4. Design Visualization and Optimization Tools

The Quartus Prime software provides various tools to help you visualize and optimize the design settings and constraints for the best design implementation.

1.4.1. Design Visualization Tools

The Quartus Prime software provides tools that display different graphical representations of your design to help you visualize and optimize placement, connectivity, and routing congestion at various stages of the design cycle.

Table 2. Design Visualization Tools

Tool	Description
Snapshot Viewer	The Compiler can preserve the results of each compilation stage as a snapshot for analysis optimization at each stage. The Snapshot Viewer allows you to easily analyze and optimize compilation results for each snapshot. The Snapshot Viewer provides centralized access to functions and tools that allow you to rapidly analyze clocking, congestion, and correct failing paths and high fan-out nets.
RTL Viewer	Provides a schematic representation of the design before synthesis and place-and-route.
Technology Map Viewer	Provides a schematic representation of the design implementation in the selected device architecture after synthesis and place-and-route. Optionally, you can include timing information.

continued...

Tool	Description
Chip Planner	Allows you to make floorplan assignments, such as Logic Lock placement constraints, and visualize critical paths and routing congestion. Click the **Report Routing Utilization** task to display the routing resource congestion.
Interface Planner	Simplifies the planning of accurate constraints for physical implementation. Use Interface Planner to prototype interface implementations, plan clocks, and rapidly define a legal device floorplan.
Design Partition Planner	Displays design entities, I/O banks, connectivity, design hierarchy, and design partition membership. Design Partition Planner can assist you in visualizing a design's structure for creating effective design partitions.

1.4.2. Design Optimization Tools

The Quartus Prime software provides tools help you identify design RTL and project settings that potentially limit performance.

Table 3. Design Optimization Tools

Tool	Description	To Access
Design Assistant	Automatically reports any violations against a standard set of Intel FPGA-recommended design guidelines, as Correct Design Assistant Rule Violations on page 74 describes.	**Assignments ➤ Settings ➤ Design Assistant Rule Settings**
Fast Forward Timing Closure Recommendations	Fast Forward compilation generates design recommendations to help you to break performance bottlenecks and maximize use of Hyper-Registers to drive the highest performance in Stratix® 10 and Agilex® 7 designs, as Implement Fast Forward Timing Closure Recommendations on page 75 describes.	On the Compilation Dashboard, click **Fast Forward Timing Closure Recommendations**.
Design Space Explorer II	Provides an easy and efficient way to run seed sweeps with different combinations of design settings and constraints to identify the optimal combination for your design, as Optimize Settings with Design Space Explorer II on page 102 describes.	**Tools ➤ Launch Design Space Explorer II**
Assignment Back-Annotation Dialog Box	Back-annotation copies the last compilation's resource assignments to preserve your optimized implementation in subsequent compilations, as Back-Annotating Optimized Assignments on page 100 describes.	**Assignments ➤ Back-Annotate Assignments**

1.5. Design Optimization Overview Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2023.04.03	23.1	• Updated product family name to "Intel Agilex 7."
2022.01.07	21.4	• Removed references to obsolete Advisors. • Added Snapshot Viewer description to *Design Visualization Tools* topic. • Removed references to Advisors from *Design Optimization Tools* topic.
2020.09.28	20.3.	• Reorganized "Design Optimization Tools" section. • Added references to Design Assistant, Fast Forward Timing Closure Recommendations, and assignment back-annotation to "Design Optimization Tools" topic. • Added Interface Planner and State Machine Viewer to list of "Design Visualization Tools". • Reworded titles in "Optimization Trade-Offs and Limitations" section for greater clarity.
2018.05.07	18.0	• General topic reorganization. • Added how DSE II works, and the main steps to follow when performing a design exploration.
2017.11.06	17.1	• Added mention to the Design Partition Planner in Design Analysis topic.
2016.10.31	16.1	• Implemented Intel rebranding.
2016.05.03	16.0	Removed statements about serial equivalence when using multiple processors.
2015.11.02	15.1	Changed instances of *Quartus II* to *Quartus Prime*.
2014.12.15	14.1	• Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Synthesis Optimizations to Compiler Settings. • Updated DSE II content.
June 2014	14.0	Updated format.
November 2013	13.1	Minor changes for HardCopy.
May 2013	13.0	Added the information about initial compilation requirements. This section was moved from the Area Optimization chapter of the Quartus Prime Handbook. Minor updates to delineate division of Timing and Area optimization chapters.
June 2012	12.0	Removed survey link.
November 2011	10.0	Template update.
December 2010	10.0	Changed to new document template. No change to content.
August 2010	10.0	Corrected link
July 2010	10.0	Initial release. Chapter based on topics and text in Section III of volume 2.

2. Optimizing the Design Netlist

You can use the Quartus Prime Netlist Viewers to analyze and debug your design netlist.

Related Information

- Quartus Prime Design Flow with the Netlist Viewers on page 16
- RTL Viewer Overview on page 17
- Technology Map Viewer Overview on page 18
- Filtering in the Schematic View on page 30
- Viewing a Timing Path on page 37

2.1. When to Use the Netlist Viewers: Analyzing Design Problems

You can use the Netlist Viewers to analyze and debug your design. The following simple examples show how to use the RTL Viewer and Technology Map Viewer to analyze problems encountered in the design process.

Using the RTL Viewer is a good way to view your initial synthesis results to determine whether you have created the necessary logic, and that the logic and connections have been interpreted correctly by the software. You can use the RTL Viewer to check your design visually before simulation or other verification processes. Catching design errors at this early stage of the design process can save you valuable time.

If you see unexpected behavior during verification, use the RTL Viewer to trace through the netlist and ensure that the connections and logic in your design are as expected. Viewing your design helps you find and analyze the source of design problems. If your design looks correct in the RTL Viewer, you know to focus your analysis on later stages of the design process and investigate potential timing violations or issues in the verification flow itself.

You can use the Technology Map Viewer to look at the results at the end of Analysis and Synthesis. If you have compiled your design through the Fitter stage, you can view your post-mapping netlist in the Technology Map Viewer (Post-Mapping) and your post-fitting netlist in the Technology Map Viewer. If you perform only Analysis and Synthesis, both the Netlist Viewers display the same post-mapping netlist.

In addition, you can use the RTL Viewer or Technology Map Viewer to locate the source of a particular signal, which can help you debug your design. Use the navigation techniques described in this chapter to search easily through your design. You can trace back from a point of interest to find the source of the signal and ensure the connections are as expected.

The Technology Map Viewer can help you locate post-synthesis nodes in your netlist and make assignments when optimizing your design. This functionality is useful when making a multicycle clock timing assignment between two registers in your design.

Start at an I/O port and trace forward or backward through the design and through levels of hierarchy to find nodes of interest, or locate a specific register by visually inspecting the schematic.

Throughout your FPGA design, debug, and optimization stages, you can use all of the netlist viewers in many ways to increase your productivity while analyzing a design.

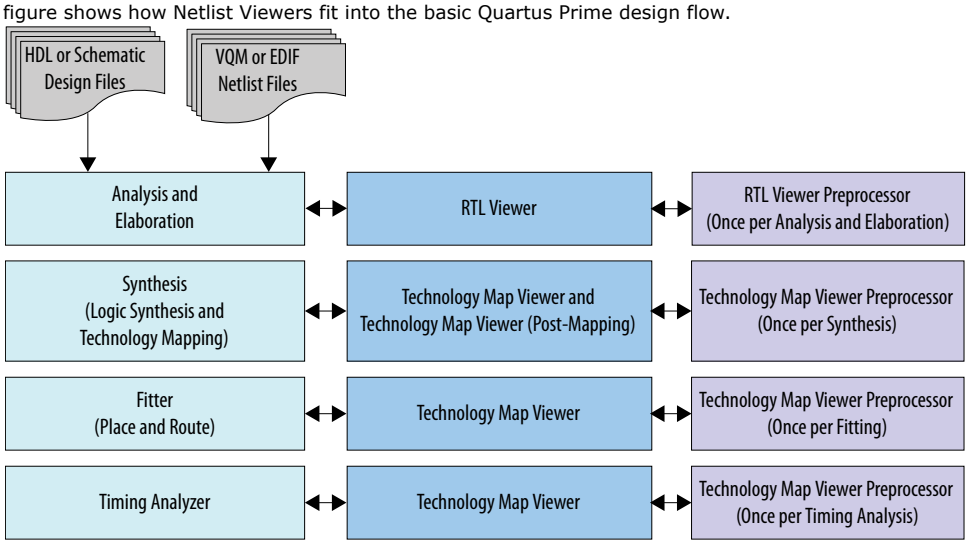
2.2. Quartus Prime Design Flow with the Netlist Viewers

When you first open one of the Netlist Viewers after compiling the design, a preprocessor stage runs automatically before the Netlist Viewer opens.

Click the link in the preprocessor process box to go to the **Settings ➤ Compilation Process Settings** page where you can turn on the **Run Netlist Viewers preprocessing during compilation** option. If you turn this option on, the preprocessing becomes part of the full project compilation flow and the Netlist Viewer opens immediately without displaying the preprocessing dialog box.

Figure 7. Quartus Prime Design Flow Including the RTL Viewer and Technology Map Viewer

This figure shows how Netlist Viewers fit into the basic Quartus Prime design flow.



Before the Netlist Viewer can run the preprocessor stage, you must compile your design:

- To open the RTL Viewer first perform Analysis and Elaboration.
- To open the Technology Map Viewer (Post-Fitting) or the Technology Map Viewer (Post-Mapping), first perform Analysis and Synthesis.

The Netlist Viewers display the results of the last successful compilation.

- Therefore, if you make a design change that causes an error during Analysis and Elaboration, you cannot view the netlist for the new design files, but you can still see the results from the last successfully compiled version of the design files.
- If you receive an error during compilation and you have not yet successfully run the appropriate compilation stage for your project, the Netlist Viewer cannot be displayed; in this case, the Quartus Prime software issues an error message when you try to open the Netlist Viewer.

Note: If the Netlist Viewer is open when you start a new compilation, the Netlist Viewer closes automatically. You must open the Netlist Viewer again to view the new design netlist after compilation completes successfully.

2.3. RTL Viewer Overview

The RTL Viewer allows you to view a register transfer level (RTL) graphical representation of Quartus Prime Pro Edition synthesis results or third-party netlist files in the Quartus Prime software.

You can view results after Analysis and Elaboration for designs that use any supported Quartus Prime design entry method, including Verilog HDL Design Files (`.v`), SystemVerilog Design Files (`.sv`), VHDL Design Files (`.vhd`), AHDL Text Design Files (`.tdf`), or schematic Block Design Files (`.bdf`).

You can also view the hierarchy of atom primitives (such as device logic cells and I/O ports) for designs that generate Verilog Quartus Mapping File (`.vqm`) or Electronic Design Interchange Format (`.edf`) files through a synthesis tool.

The RTL Viewer displays a schematic view of the design netlist after Analysis and Elaboration or after the Quartus Prime software performs netlist extraction, but before technology mapping and synthesis or fitter optimizations. This view a preliminary pre-optimization design structure and closely represents the original source design.

- For designs synthesized with the Quartus Prime Pro Edition synthesis, this view shows how the Quartus Prime software interprets the design files.
- For designs synthesized with a third-party synthesis tool, this view shows the netlist that the synthesis tool generates.

To run the RTL Viewer for an Quartus Prime project, first analyze the design to generate an RTL netlist. To analyze the design and generate an RTL netlist, click **Processing ➤ Start ➤ Start Analysis & Elaboration**. You can also perform a full compilation on any process that includes the initial Analysis and Elaboration stage of the Quartus Prime compilation flow.

To open the RTL Viewer, click **Tools ➤ Netlist Viewers ➤ RTL Viewer**.

2.3.1. Maximizing Readability in RTL Viewer

While displaying a design, the RTL Viewer optimizes the netlist to maximize readability:

- Removes logic with no fan-out (unconnected output) or fan-in (unconnected inputs) from the display.
- Hides default connections such as V_{CC} and GND.
- Groups pins, nets, wires, module ports, and certain logic into buses where appropriate.
- Groups constant bus connections.
- Displays values in hexadecimal format.
- Converts NOT gates into bubble inversion symbols in the schematic.
- Merges chains of equivalent combinational gates into a single gate; for example, a 2-input AND gate feeding a 2-input AND gate is converted to a single 3-input AND gate.

2.3.2. Running the RTL Viewer

To run the RTL Viewer for an Quartus Prime project:

1. Analyze the design to generate an RTL netlist by clicking **Processing ➤ Start ➤ Start Analysis & Elaboration**.

   You can also perform a full compilation on any process that includes the initial Analysis and Elaboration stage of the Quartus Prime compilation flow.
2. Open the RTL Viewer by clicking **Tools ➤ Netlist Viewers ➤ RTL Viewer**.

2.4. Technology Map Viewer Overview

The Quartus Prime Technology Map Viewer provides a technology-specific, graphical representation of FPGA designs after Analysis and Synthesis or after the Fitter maps the design into the target device.

The Technology Map Viewer shows the hierarchy of atom primitives (such as device logic cells and I/O ports) in the design. For supported device families, you can also view internal registers and look-up tables (LUTs) inside logic cells (LCELLs), and registers in I/O atom primitives.

Where possible, the Quartus Prime software maintains the port names of each hierarchy throughout synthesis. However, the software may change or remove port names from the design. For example, the software removes ports that are unconnected or driven by GND or V_{CC} during synthesis. If a port name changes, the software assigns a related user logic name in the design or a generic port name such as `IN1` or `OUT1`.

You can view Quartus Prime technology-mapped results after synthesis, fitting, or timing analysis. To run the Technology Map Viewer for an Quartus Prime project, on the **Processing** menu, point to **Start** and click **Start Analysis & Synthesis** to synthesize and map the design to the target technology. At this stage, the Technology Map Viewer shows the same post-mapping netlist as the Technology Map Viewer (Post-Mapping). You can also perform a full compilation, or any process that includes the synthesis stage in the compilation flow.

For designs that completed the Fitter stage, the Technology Map Viewer shows how the Fitter changed the netlist through physical synthesis optimizations, while the Technology Map Viewer (Post-Mapping) shows the post-mapping netlist. If you have completed the Timing Analysis stage, you can locate timing paths from the Timing Analyzer report in the Technology Map Viewer.

To open the Technology Map Viewer, click **Tools ➤ Netlist Viewers ➤ Technology Map Viewer (Post-Fitting)** or **Technology Map Viewer (Post Mapping)**.

Related Information

- Viewing a Timing Path on page 37
- View Contents of Nodes in the Schematic View on page 30

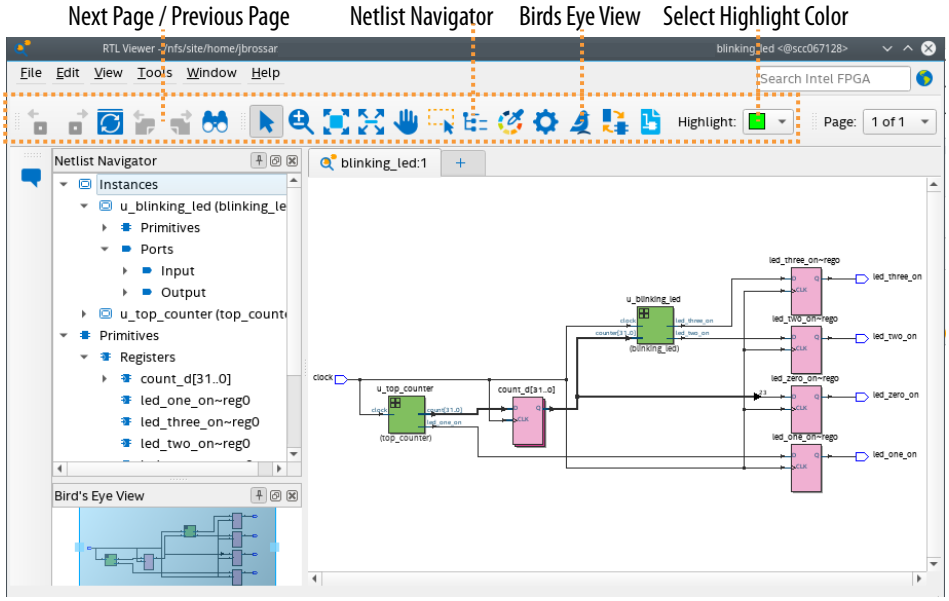
2.5. Netlist Viewer User Interface

The Netlist Viewer is a graphical user-interface for viewing and manipulating nodes and nets in the netlist.

The RTL Viewer and Technology Map Viewer each consist of these main parts:

- The **Netlist Navigator** pane—displays a representation of the project hierarchy.
- The **Find** pane—allows you to find and locate specific design elements in the schematic view.
- The **Properties** pane—displays the properties of the selected block when you select **Properties** from the shortcut menu.
- The schematic view—displays a graphical representation of the internal structure of the design.

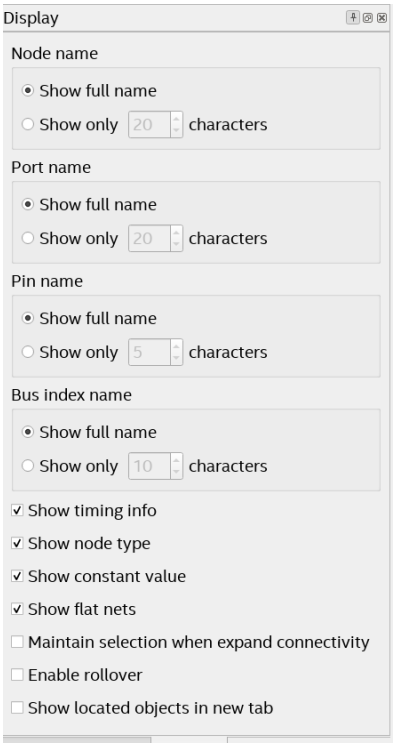
Figure 8. RTL Viewer



Netlist Viewers also contain a toolbar that provides tools to use in the schematic view.

- Use the **Back** and **Forward** buttons to switch between schematic views.
- Click the **Next Page** or **Previous Page** buttons to navigate directly to the next or previous page, respectively. These buttons are helpful when a long schematic partitions to multiple pages.
- The **Refresh** button to restore the schematic view and optimizes the layout. **Refresh** does not reload the database if you change the design and recompile.
- Click the **Find** button opens and closes the **Find** pane.
- Click the **Selection Tool** and **Zoom Tool** buttons to alternate between the selection mode and zoom mode.
- Click the **Fit in Window** button resets the schematic view to encompass the entire design.
- Click the **Fit Selection in Window** button resets the schematic view to encompass the entire selection.
- Use the **Hand Tool** to change the focus of the viewer without changing the perspective.
- Click the **Area Selection Tool** to drag a selection box around ports, pins, and nodes in an area.
- Click the **Netlist Navigator** button to open or close the **Netlist Navigator** pane.
- Click the **Color Settings** button to open the **Colors** pane where you can customize the Netlist Viewer color scheme.

Figure 9. Display Settings



- Click the **Display Settings** button to open the **Display** pane where you can specify the following settings:
  - **Show full name** or **Show only <*n*> characters**. You can specify this separately for **Node name**, **Port name**, **Pin name**, or **Bus index name**.
  - Turn **Show timing info** on or off.
  - Turn **Show node type** on or off.
  - Turn **Show constant value** on or off.
  - Turn **Show flat nets** on or off.
  - Turn **Maintain selection when expand hierarchy** on or off.
  - Turn **Enable rollover** on or off.
  - Turn **Show located objects in new tab** on or off.
- The **Bird's Eye View** button opens the **Bird's Eye View** window which displays a miniature version of the design and allows you to navigate within the design and adjust the magnification in the schematic view quickly.
- The **Show/Hide Instance Pins** button can alternate the display of instance pins not displayed by functions such as cross-probing between a Netlist Viewer and Timing Analyzer. You can also use this button to hide unconnected instance pins when filtering a node results in large numbers of unconnected or unused pins. The Netlist Viewer hides Instance pins by default.
- If the Netlist Viewer display encompasses several pages, the **Show Netlist on One Page** button resizes the netlist view to a single page. This action can make netlist tracing easier.
- Click the **Highlight** list to apply a highlight color to the objects that you select in the schematic. Unhighlight objects with **Unhighlight** or **Unhighlight All** from the right-click menu.

You can have only one RTL Viewer, one Technology Map Viewer (Post-Fitting), and one Technology Map Viewer (Post-Mapping) window open at the same time, although each window can show multiple pages, each with multiple tabs. For example, you cannot have two RTL Viewer windows open at the same time.

Related Information

- Netlist Navigator Pane on page 21
- Netlist Viewers Find Pane on page 23
- Properties Pane on page 22

2.5.1. Netlist Navigator Pane

The **Netlist Navigator** pane displays the entire netlist in a tree format based on the hierarchical levels of the design. Each level groups similar elements into subcategories.

The **Netlist Navigator** pane allows you to traverse through the design hierarchy to view the logic schematic for each level. You can also select an element in the **Netlist Navigator** to highlight in the schematic view.

Note: The **Netlist Navigator** pane does not list nodes inside atom primitives.

For each module in the design hierarchy, the **Netlist Navigator** pane displays the applicable elements listed in the following table. Click the "**+**" icon to expand an element.

Table 4. Netlist Navigator Pane Elements

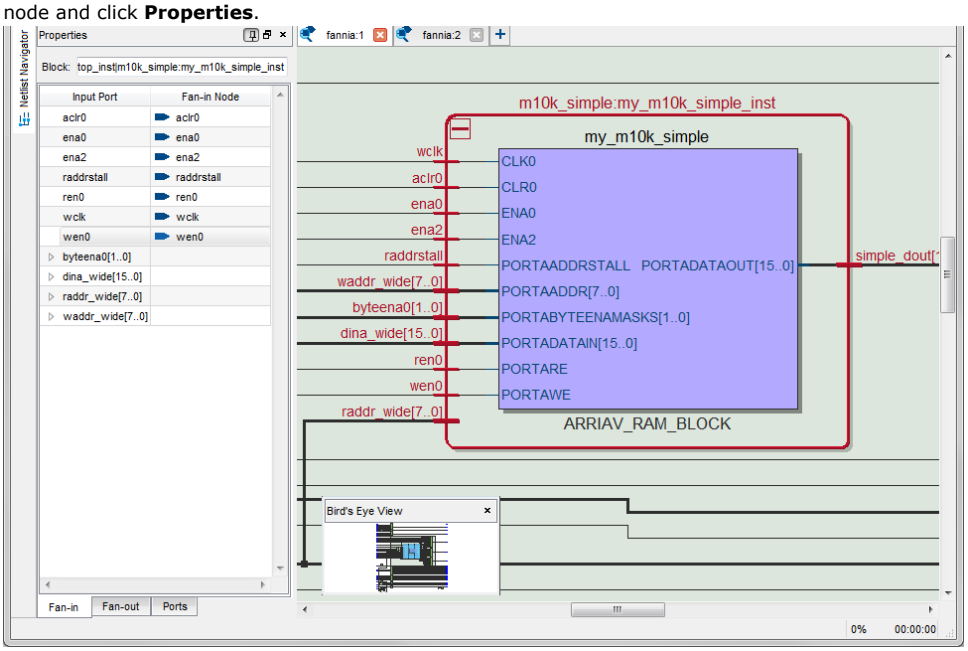
Elements	Description
Instances	Modules or instances in the design that can be expanded to lower hierarchy levels.
Primitives	Low-level nodes that cannot be expanded to any lower hierarchy level. These primitives include: • Registers and gates that you can view in the RTL Viewer when using Quartus Prime Pro Edition synthesis. • Logic cell atoms in the Technology Map Viewer or in the RTL Viewer when using a VQM or EDIF from third-party synthesis software In the Technology Map Viewer, you can view the internal implementation of certain atom primitives, but you cannot traverse into a lower-level of hierarchy.
Ports	The I/O ports in the current level of hierarchy. • Pins are device I/O pins when viewing the top hierarchy level and are I/O ports of the design when viewing the lower-levels. • When a pin represents a bus or an array of pins, expand the pin entry in the list view to see individual pin names.

2.5.2. Properties Pane

You can view the properties of an instance or primitive with the **Properties** pane.

Figure 10. Properties Pane

To view the properties of an instance or primitive in the RTL Viewer or Technology Map Viewer, right-click the node and click **Properties**.



The **Properties** pane contains tabs with the following information about the selected node:

- The **Fan-in** tab displays the **Input port** and **Fan-in Node**.
- The **Fan-out** tab displays the **Output port** and **Fan-out Node**.
- The **Parameters** tab displays the **Parameter Name** and **Values** of an instance.
- The **Ports** tab displays the **Port Name** and **Constant** value (for example, V_{CC} or GND). The following table lists the possible values of a port:

Table 5. Possible Port Values

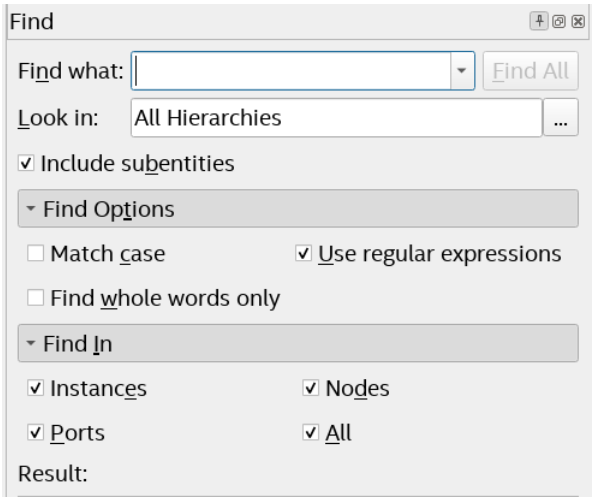
Value	Description
V_{CC}	The port is not connected and has V_{CC} value (tied to V_{CC})
GND	The port is not connected and has GND value (tied to GND)
--	The port is connected and has value (other than V_{CC} or GND)
Unconnected	The port is not connected and has no value (hanging)

If the selected node is an atom primitive, the **Properties** pane displays a schematic of the internal logic.

2.5.3. Netlist Viewers Find Pane

You can narrow the range of the search process by setting the following options in the **Find** pane:

Figure 11. Find Options



- Click **Browse** (…) next to **Look in** to specify the hierarchy level of the search. In the **Select Hierarchy Level** dialog box, you can select a particular instance you want to search.
- Turn on the **Include subentities** option to include child hierarchies of the parent instance during the search.
- Under **Find Options**, turn on or off **Match case**, **Use regular expressions**, **Find whole words only**, or any combination of the three option, to further refine the parameters of the search.
- Under **Find In**, turn on or off **Instances**, **Ports**, **Nodes**, **All** or any combination of options, to further refine the parameters of the search.

When you click the **Find All** button, a progress bar appears below the **Find** box.

All results that match the criteria you set are listed in a table. When you double-click an item in the table, the related node is highlighted in red in the schematic view.

2.6. Schematic View

The schematic view is shown on the right side of the RTL Viewer and Technology Map Viewer. The schematic view contains a schematic representing the design logic in the netlist. This view is the main screen for viewing your gate-level netlist in the RTL Viewer and your technology-mapped netlist in the Technology Map Viewer.

The RTL Viewer and Technology Map Viewer attempt to display schematic in a single page view by default. If the schematic crosses over to several pages, you can highlight a net and use connectors to trace the signal in a single page.

2.6.1. Display Schematics in Multiple Tabbed View

The RTL Viewer and Technology Map Viewer support multiple tabbed views.

With multiple tabbed view, schematics can be displayed in different tabs. Selection is independent between tabbed views, but selection in the tab in focus is synchronous with the Netlist Navigator pane.

To create a new blank tab, click the **New Tab** button at the end of the tab row . You can now drag a node from the **Netlist Navigator** pane into the schematic view.

Right-click in a tab to see a shortcut menu to perform the following actions:

- Create a blank view with **New Tab**
- Create a **Duplicate Tab** of the tab in focus
- Choose to **Cascade Tabs**
- Choose to **Tile Tabs**
- Choose **Close Tab** to close the tab in focus
- Choose **Close Other Tabs** to close all tabs except the tab in focus

2.6.2. Schematic Symbols

The symbols for nodes in the schematic represent elements of your design netlist. These elements include input and output ports, registers, logic gates, Intel primitives, high-level operators, and hierarchical instances.

Note: The logic gates and operator primitives appear only in the RTL Viewer. Logic in the Technology Map Viewer is represented by atom primitives, such as registers and LCELLs.

Table 6. Symbols in the Schematic View

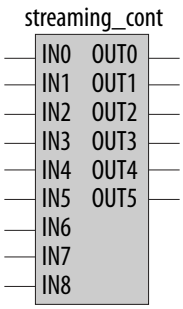
This table lists and describes the primitives and basic symbols that you can display in the schematic view of the RTL Viewer and Technology Map Viewer.

Symbol	Description
Wire indicator and net ripper 	Indicates the net signal flow direction into or out of the pin or port. There can be symbols in both directions due to automatic net bundling from the connectivity. You can click the net to highlight the signal flow details in the schematic.
I/O Ports  	An input, output, or bidirectional port in the current level of hierarchy. A device input, output, or bidirectional pin when viewing the top-level hierarchy. The symbol can also represent a bus. Only one wire is shown connected to the bidirectional symbol, representing the input and output paths. Input symbols appear on the left-most side of the schematic. Output and bidirectional symbols appear on the right-most side of the schematic.
I/O Connectors  	An input or output connector, representing a net that comes from another page of the same hierarchy. To go to the page that contains the source or the destination, double-click the connector to jump to the appropriate page.
OR, AND, XOR Gates   	An OR, AND, or XOR gate primitive (the number of ports can vary). A small circle (bubble symbol) on an input or output port indicates the port is inverted.
MULTIPLEXER 	A multiplexer primitive with a selector port that selects between port `0` and port `1`. A multiplexer with more than two inputs is displayed as an operator.

continued...

Symbol	Description
BUFFER 	A buffer primitive. The figure shows the tri-state buffer, with an inverted output enable port. Other buffers without an enable port include LCELL, SOFT, and GLOBAL. The NOT gate and EXP expander buffers use this symbol without an enable port and with an inverted output port.
LATCH 	A latch/DFF (data flipflop) primitive. A DFF has the same ports as a latch and a clock trigger. The other flipflop primitives are similar: • DFFEA (data flipflop with enable and asynchronous load) primitive with additional ALOAD asynchronous load and ADATA data signals • DFFEAS (data flipflop with enable and synchronous and asynchronous load), which has ASDATA as the secondary data port
Atom Primitive 	An atom primitive. The symbol displays the atom name, the port names, and the atom type. The blue shading indicates an atom primitive for which you can view the internal details.
Other Primitive 	Any primitive that does not fall into the previous categories. Primitives are low-level nodes that cannot be expanded to any lower hierarchy. The symbol displays the port names, the primitive or operator type, and its name.
Instance 	An instance in the design that does not correspond to a primitive or operator (a user-defined hierarchy block). The symbol displays the port name and the instance name.
Encrypted Instance	A user-defined encrypted instance in the design. The symbol displays the instance name. You cannot open the schematic for the lower-level hierarchy, because the source design is encrypted.

continued...

Symbol	Description
	


RAM 	A synchronous memory instance with registered inputs and optionally registered outputs. The symbol shows the device family and the type of memory block. This figure shows a true dual-port memory block in a Stratix M-RAM block.
Constant 	A constant signal value that is highlighted in gray and displayed in hexadecimal format by default throughout the schematic.

Table 7. Operator Symbols in the RTL Viewer Schematic View

The following lists and describes the additional higher level operator symbols in the RTL Viewer schematic view.

Symbol	Description
	An adder operator: `OUT = A + B`

continued...

Symbol	Description
	A multiplier operator: `OUT = A ¥ B`
	A divider operator: `OUT = A / B`
	Equals
	A left shift operator: `OUT = (A << COUNT)`
	A right shift operator: `OUT = (A >> COUNT)`
	A modulo operator: `OUT = (A%B)`
	A less than comparator: `OUT = (A<:B:A>B)`
	A multiplexer: `OUT = DATA [SEL]` The data range size is $2^{\text{sel range size}}$

continued...

Symbol	Description
	A selector: A multiplexer with one-hot select input and more than two input signals
	A binary number decoder: `OUT = (binary_number (IN) == x)` for x = 0 to $x = 2^{(n+1)} - 1$

Related Information

- Partition the Schematic into Pages on page 35
- Follow Nets Across Schematic Pages on page 35

2.6.3. Select Items in the Schematic View

To select an item in the schematic view, ensure that the **Selection Tool** is enabled in the Netlist Viewer toolbar. Click an item in the schematic view to highlight in red.

Select multiple items by pressing the Shift key while selecting with the mouse.

Items selected in the schematic view are automatically selected in the **Netlist Navigator** pane. The folder then expands automatically if it is required to show the selected entry; however, the folder does not collapse automatically when you deselected the entries.

When you select a hierarchy box, node, or port in the schematic view, the Schematic View highlights the item in red, but not the connecting nets. When you select a net (wire or bus) in the schematic view, the Schematic View highlights all connected nets in red.

Once you select an item, you can perform different actions on it based on the contents of the shortcut menu which appears when you right-click your selection.

Related Information

Netlist Navigator Pane on page 21

2.6.4. Shortcut Menu Commands in the Schematic View

When you right-click a selected instance or primitive in the schematic view, the Netlist Viewer displays a shortcut menu.

If the selected item is a node, you see the following options:

- Click **Expand to Upper Hierarchy** to displays the parent hierarchy of the node in focus.
- Click **Copy ToolTip** to copy the selected item name to the clipboard. This command does not work on nets.
- Click **Hide Selection** to remove the selected item from the schematic view. This command does not delete the item from the design, merely masks it in the current view.
- Click **Filtering** to display a sub-menu with options for filtering your selection.

2.6.5. Filtering in the Schematic View

Filtering allows you to filter out nodes and nets in a netlist to view only the logic elements of interest to you.

You can filter a netlist by selecting hierarchy boxes, nodes, or ports of a node, that are part of the path you want to see. The following filter commands are available:

- **Sources**—displays the sources of the selection.
- **Destinations**—displays the destinations of the selection.
- **Sources & Destinations**—displays the sources and destinations of the selection.
- **Selected Nodes**—displays only the selected nodes.
- **Between Selected Nodes**—displays nodes and connections in the path between the selected nodes.
- **Bus Index**—Displays the sources or destinations for one or more indexes of an output or input bus port.
- **Filtering Options**—Displays the **Filtering Options** dialog box:
  - **Stop filtering at register**—Turning on this option directs the Netlist Viewer to filter out to the nearest register boundary.
  - **Filter across hierarchies**—Turning on this option directs the Netlist Viewer to filter across hierarchies.
  - **Maximum number of hierarchy levels**—Sets the maximum number of hierarchy levels that the schematic view can display.

To filter a netlist, select a hierarchy box, node, port, net, or state node, right-click in the window, point to **Filter** and click the appropriate filter command. The Netlist Viewer generates a new page showing the netlist that remains after filtering.

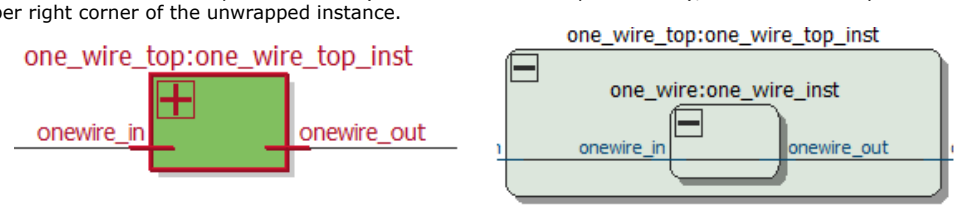
2.6.6. View Contents of Nodes in the Schematic View

In the RTL Viewer and the Technology Map Viewer, you can view the contents of nodes to see their underlying implementation details.

You can view LUTs, registers, and logic gates. You can also view the implementation of RAM and DSP blocks in certain devices in the RTL Viewer or Technology Map Viewer. In the Technology Map Viewer, you can view the contents of primitives to see their underlying implementation details.

Figure 12. Wrapping and Unwrapping Objects

If you can unwrap the contents of an instance, a plus symbol appears in the upper right corner of the object in the schematic view. To wrap the contents (and revert to the compact format), click the minus symbol in the upper right corner of the unwrapped instance.



Note: In the schematic view, the internal details in an atom instance cannot be selected as individual nodes. Any mouse action on any of the internal details is treated as a mouse action on the atom instance.

Figure 13. Nodes with Connections Outside the Hierarchy

In some cases, the selected instance connects to something outside the visible level of the hierarchy in the schematic view. In this case, the net appears as a dotted line. Double-click the dotted line to expand the view to display the destination of the connection .

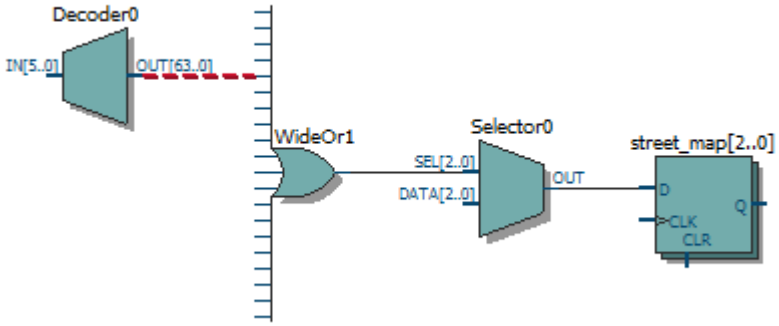


Figure 14. Display Nets Across Hierarchies

In cases where the net connects to an instance outside the hierarchy, you can select the net, and unwrap the node to see the destination ports.

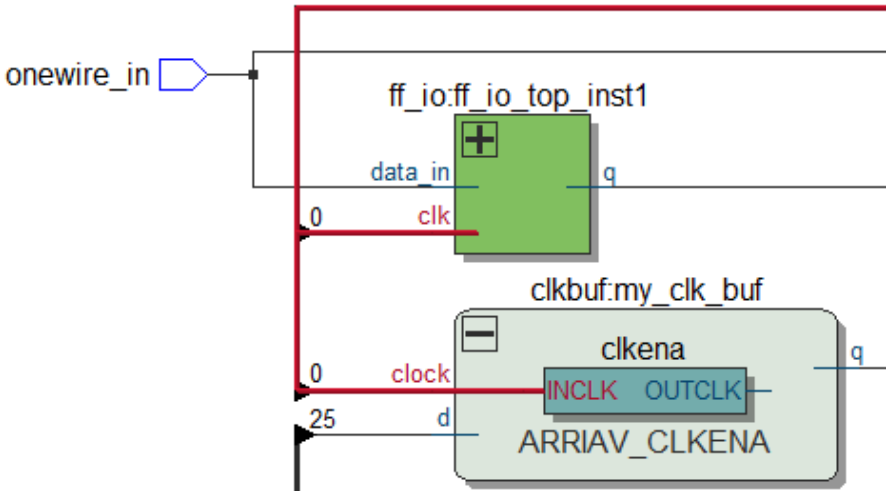

Figure 15. Show Connectivity Details

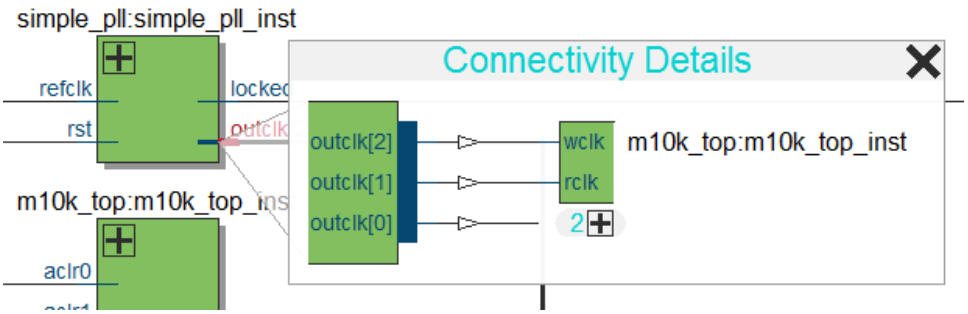
You can select a port, pin, bus port or bus pin and click **Connectivity Details** in the context menu for that object.



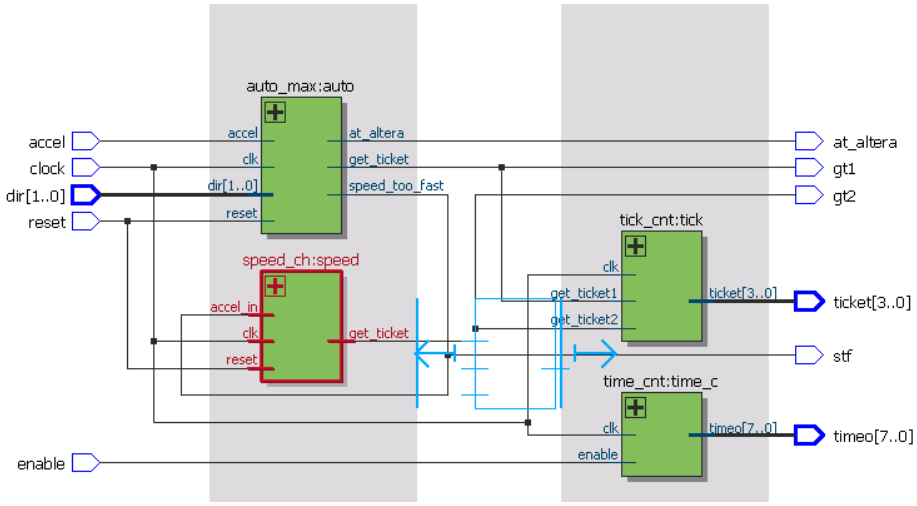
You can double-click objects in the **Connectivity Details** window to navigate to them quickly. If the plus symbol appears, you can further unwrap objects in the view. This can be very useful when tracing a signal in a complex netlist.

2.6.7. Moving Nodes in the Schematic View

Rearrange items in the schematic view by dragging to destination.

To move a node from one area of the netlist to another, select the node and hold down the Shift key. Legal placements appear as shaded areas within the hierarchy. Click to drop the selected node.

Figure 16. Legal Placement when Moving Nodes



To restore the schematic view to its default arrangement, right-click and click **Refresh**.

2.6.8. View LUT Representations in the Technology Map Viewer

You can view different representations of a LUT by right-clicking the selected LUT and clicking **Properties**.

You can view the LUT representations in the following three tabs in the **Properties** dialog box:

- The **Schematic** tab—the equivalent gate representations of the LUT.
- The **Truth Table** tab—the truth table representations.

Note: LUT representations in the Tech Map Viewer are only available for Arria® 10 devices and Cyclone® 10 GX devices in the Quartus Prime Pro Edition software.

Related Information

Properties Pane on page 22

2.6.9. Zoom Controls

Use the Zoom Tool in the toolbar, or mouse gestures, to control the magnification of your schematic on the View menu.

By default, the Netlist Viewer displays most pages sized to fit in the window. If the schematic page is very large, the schematic is displayed at the minimum zoom level, and the view is centered on the first node. Click **Zoom In** to view the image at a larger size, and click **Zoom Out** to view the image (when the entire image is not displayed) at a smaller size. The **Zoom** command allows you to specify a magnification percentage (100% is considered the normal size for the schematic symbols).

You can use the Zoom Tool on the Netlist Viewer toolbar to control magnification in the schematic view. When you select the Zoom Tool in the toolbar, clicking in the schematic zooms in and centers the view on the location you clicked. Right-click in the schematic to zoom out and center the view on the location you clicked. When you select the Zoom Tool, you can also zoom into a certain portion of the schematic by selecting a rectangular box area with your mouse cursor. The schematic is enlarged to show the selected area.

Within the schematic view, you can also use the following mouse gestures to zoom in on a specific section:

- **zoom in**—Dragging a box around an area starting in the upper-left and dragging to the lower right zooms in on that area.
- **zoom -0.5**—Dragging a line from lower-left to upper-right zooms out 0.5 levels of magnification.
- **zoom 0.5**—Dragging a line from lower-right to upper-left zooms in 0.5 levels of magnification.
- **zoom fit**—Dragging a line from upper-right to lower-left fits the schematic view in the page.

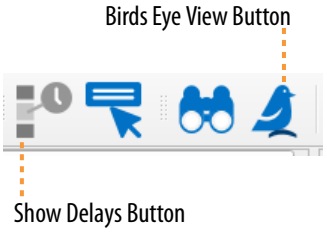
Related Information

Filtering in the Schematic View on page 30

2.6.10. Navigating with the Bird's Eye View

To open the Bird's Eye View, on the View menu, click **Bird's Eye View**, or click the **Bird's Eye View** icon in the toolbar.

Figure 17. Birds Eye View Button on Chip Planner Toolbar



Viewing the entire schematic can be useful when debugging and tracing through a large netlist. The Quartus Prime software allows you to quickly navigate to a specific section of the schematic using the Bird's Eye View feature, which is available in the RTL Viewer and Technology Map Viewer.

The Bird's Eye View shows the current area of interest:

- Select an area by clicking and dragging the indicator or right-clicking to form a rectangular box around an area.
- Click and drag the rectangular box to move around the schematic.
- Resize the rectangular box to zoom-in or zoom-out in the schematic view.

2.6.11. Partition the Schematic into Pages

For large design hierarchies, the RTL Viewer and Technology Map Viewer partition your netlist into multiple pages in the schematic view.

When a hierarchy level is partitioned into multiple pages, the title bar for the schematic window indicates which page is displayed and how many total pages exist for this level of hierarchy. The schematic view displays this as **Page** <*current page number*> **of** <*total number of pages*>.

Related Information

Netlist Viewer User Interface on page 19

2.6.12. Follow Nets Across Schematic Pages

Input and output connector symbols indicate nodes that connect across pages of the same hierarchy. Double-click a connector to trace the net to the next page of the hierarchy.

Note: After you double-click to follow a connector port, the Netlist Viewer opens a new page, which centers the view on the particular source or destination net using the same zoom factor as the previous page. To trace a specific net to the new page of the hierarchy, Intel recommends that you first select the necessary net, which highlights it in red, before you double-click to navigate across pages.

Related Information

Schematic Symbols on page 24

2.7. Cross-Probing to a Source Design File and Other Quartus Prime Windows

The RTL Viewer and Technology Map Viewer allow you to cross-probe to the source design file and to various other windows in the Quartus Prime software.

You can select one or more hierarchy boxes, nodes, state nodes, or state transition arcs that interest you in the Netlist Viewer and locate the corresponding items in another applicable Quartus Prime software window. You can then view and make changes or assignments in the appropriate editor or floorplan.

To locate an item from the Netlist Viewer in another window, right-click the items of interest in the schematic or state diagram, point to **Locate**, and click the appropriate command. The following commands are available:

- **Locate in Assignment Editor**
- **Locate in Pin Planner**
- **Locate in Chip Planner**
- **Locate in Resource Property Editor**
- **Locate in Technology Map Viewer**
- **Locate in RTL Viewer**
- **Locate in Design File**

The options available for locating an item depend on the type of node and whether it exists after placement and routing. If a command is enabled in the menu, it is available for the selected node. You can use the **Locate in Assignment Editor** command for all nodes, but assignments might be ignored during placement and routing if they are applied to nodes that do not exist after synthesis.

The Netlist Viewer automatically opens another window for the appropriate editor or floorplan and highlights the selected node or net in the newly opened window. You can switch back to the Netlist Viewer by selecting it in the Window menu or by closing, minimizing, or moving the new window.

2.8. Cross-Probing to the Netlist Viewers from Other Quartus Prime Windows

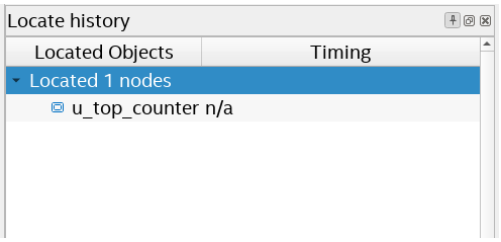
You can cross-probe to the RTL Viewer and Technology Map Viewer from other windows in the Quartus Prime software. You can select one or more nodes or nets in another window and locate them in one of the Netlist Viewers.

You can locate nodes between the RTL Viewer and Technology Map Viewer, and you can locate nodes in the RTL Viewer and Technology Map Viewer from the following Quartus Prime software windows:

- Project Navigator
- Chip Planner
- Resource Property Editor
- Node Finder
- Assignment Editor
- Messages Window
- Compilation Report
- Timing Analyzer (supports the Technology Map Viewer only)

To locate elements in the Netlist Viewer from another Quartus Prime window, select the node or nodes in the appropriate window; for example, select an entity in the **Entity** list on the **Hierarchy** tab in the Project Navigator, or select nodes in the Timing Closure Floorplan, or select node names in the **From** or **To** column in the Assignment Editor. Next, right-click the selected object, point to **Locate**, and click **Locate in RTL Viewer** or **Locate in Technology Map Viewer**. After you click this command, the Netlist Viewer opens, or is brought to the foreground if the Netlist Viewer is open. In addition, the **Locate history** pane displays a list of the items that you locate. Use the **Locate history** pane to easily rerun cross-probing directly within the RTL Viewer or Technology Map Viewer. The **Show located objects in new tab** option always displays the found items in a new tab, as Netlist Viewer User Interface on page 19 describes.

Figure 18. Locate History Pane



Note: The first time the window opens after a compilation, the preprocessor stage runs before the Netlist Viewer opens.

The Netlist Viewer shows the selected nodes and, if applicable, the connections between the nodes. The display is similar to what you see if you right-click the object, then click **Filter ➤ Selected Nodes** using **Filter across hierarchy**. If the nodes cannot be found in the Netlist Viewer, a message box displays the message: **Can't find requested location**.

2.9. Viewing a Timing Path

After completing a full design compilation, including the timing analyzer stage, you can see a visual representation of a timing path cross-probe from a timing report. For details about generating the timing report, refer to the *Quartus Prime Pro Edition User Guide: Timing Analyzer*.

When you locate the timing path from the Timing Analyzer to the Technology Map Viewer, the interconnect and cell delay associated with each node appears on top of the schematic symbols. The total slack of the selected timing path appears in the Page Title section of the schematic.

1. To open the report from the **Compilation Report** Table of Contents, click **Timing Analyzer GUI ➤ Report Timing**, and double-click the timing corner.
2. To open the report from the **Timing Analyzer**, open the **Report Timing** folder in the **Report** pane, and double-click the timing corner.
3. In the **Summary of Paths** tab, right-click a row in the table and select **Locate Path ➤ Locate in Technology Map Viewer**. In the Technology Map Viewer, the schematic page displays the nodes along the timing path with a summary of the total delay.

2.10. Optimizing the Design Netlist Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout. • Added device support note to *View LUT Representations in the Technology Map Viewer* topic.
2023.08.01	21.3	• Replaced missing graphics in *Navigating with the Bird's Eye View*.
2021.10.04	21.3	• Updated *Netlist Viewer User Interface* topic to add Fix Selection in Window, Unhighlight, and other new GUI controls. • Updated *Netlist Viewers Find Pane* topic for new Find Options and Find In controls. • Updated *Schematic Symbols* topic for wire indicator symbol. • Updated *Show Connectivity Details* figure for port or pin. • Updated *Cross-Probing to the Netlist Viewers from Other Intel Quartus Prime Windows* topic for Locate History panel.
2019.07.01	19.1	Added *Maintaining Selection in the Resource Property Viewer* topic explaining how the iterm-oterm dependency is maintained in the schematic view.
2018.09.24	18.1.0	• Added link to *Viewing a Timing Path*. • Removed reference to unsupported CARRY buffer from "Schematic Symbols" topic.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2016.05.03	16.0.0	Removed Schematic Viewer topic.
2015.11.02	15.1.0	Added Schematic Viewer topic for viewing stage snapshots. Added information for the following new features and feature updates: • Nets visible across hierarchies • Connection Details • Display Settings • Hand Tool • Area Selection Tool • New default behavior for Show/Hide Instance Pins (default is now off)
2014.06.30	14.0.0	Added Show Netlist on One Page and show/Hide Instance Pins commands.
November 2013	13.1.0	Removed HardCopy device information. Reorganized and migrated to new template. Added support for new Netlist viewer.
November 2012	12.1.0	Added sections to support Global Net Routing feature.
June 2012	12.0.0	Removed survey link.
November 2011	10.0.2	Template update.
December 2010	10.0.1	Changed to new document template.
July 2010	10.0.0	• Updated screenshots • Updated chapter for the Quartus Prime software version 10.0, including major user interface changes
November 2009	9.1.0	• Updated devices • Minor text edits

continued...

Document Version	Quartus Prime Version	Changes
March 2009	9.0.0	• Chapter 13 was formerly Chapter 12 in version 8.1.0 • Updated Figure 13–2, Figure 13–3, Figure 13–4, Figure 13–14, and Figure 13–30 • Added "Enable or Disable the Auto Hierarchy List" on page 13–15 • Updated "Find Command" on page 13–44
November 2008	8.1.0	Changed page size to 8.5" × 11"
May 2008	8.0.0	• Added Arria GX support • Updated operator symbols • Updated information about the radial menu feature • Updated zooming feature • Updated information about probing from schematic to Signal Tap Analyzer • Updated constant signal information • Added .png and .gif to the list of supported image file formats • Updated several figures and tables • Added new sections "Enabling and Disabling the Radial Menu", "Changing the Time Interval", "Changing the Constant Signal Value Formatting", "Logic Clouds in the RTL Viewer", "Logic Clouds in the Technology Map Viewer", "Manually Group and Ungroup Logic Clouds", "Customizing the Shortcut Commands" • Renamed several sections • Removed section "Customizing the Radial Menu" • Moved section "Grouping Combinational Logic into Logic Clouds" • Updated document content based on the Quartus Prime software version 8.0

3. Netlist Optimizations and Physical Synthesis

The Quartus Prime software offers netlist optimizations during synthesis, and physical synthesis optimization during fitting, that can improve the performance of your design. Synthesis netlist optimizations operate with the atom netlist of your design, which describes a design in terms of specific primitives. This chapter provides guidelines for applying synthesis and physical synthesis optimization settings.

You can access a range of global synthesis and physical synthesis optimization settings from the **Compiler Settings** page:

Table 8. Synthesis Netlist Optimization and Physical Synthesis Options

Options	Location/Description
Enable synthesis netlist optimization settings	Enable synthesis optimization options (for example, **Synthesis Effort**) in the **Advanced Synthesis Settings** dialog box. Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)** to access these options.
Enable physical synthesis options	Enable physical synthesis options (for example, **Advanced Physical Synthesis**) in the **Advanced Fitter Settings** dialog box. Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)** to access these settings.

Note: Because the node names for primitives in the design can change when you use physical synthesis optimizations, you should evaluate whether your design depends on fixed node names. If you use a verification flow that might require fixed node names, such as the Signal Tap Logic Analyzer, formal verification, or the Logic Lock based optimization flow (for legacy devices), disable physical synthesis options.

3.1. Physical Synthesis Optimizations

The Quartus Prime Fitter places and routes the logic cells to ensure critical portions of logic are close together and use the fastest possible routing resources. However, routing delays are often a significant part of the typical critical path delay. Physical synthesis optimizations take into consideration placement information, routing delays, and timing information to determine the optimal placement. The Fitter then focuses timing-driven optimizations at those critical parts of the design. The tight integration of the synthesis and fitting processes is known as physical synthesis.

The following sections describe the physical synthesis optimizations available in the Quartus Prime software, and how they can help improve performance and fitting for the selected device.

Related Information

Compiler Settings Page (Settings Dialog Box)
In *Quartus Prime Help*

3.1.1. Disabling or Enabling Physical Synthesis Optimization

Physical synthesis optimization improves circuit performance by performing combinational and sequential optimization and register duplication.

The Compiler performs physical synthesis optimization by default during place and route. You can disable or enable physical synthesis optimization and related options by following these steps:

To disable or enable physical synthesis optimization:

1. Click **Assignments ➤ Settings ➤ Compiler Settings**.
2. To enable retiming, combinational optimization, and register duplication, click **Advanced Settings (Fitter)**.
3. Enable **Advanced Physical Synthesis**.
4. View physical synthesis results in the **Netlist Optimizations** report under **Compilation Report ➤ Fitter** section.

3.1.2. Physical Synthesis Options

The Quartus Prime software provides physical synthesis optimization options to improve fitting results. To access these options, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**.

Note: To disable global physical synthesis optimizations for specific elements of your design, assign the **Netlist Optimizations** logic option to **Never Allow** to the specific nodes or entities.

Table 9. Physical Synthesis Options

Option	Description
Advanced Physical Synthesis	Uses the physical synthesis engine to perform combinational and sequential optimization during fitting to improve circuit performance.
Netlist Optimizations	You can use the Assignment Editor to apply the **Netlist Optimizations** logic option. Use this option to disable physical synthesis optimizations for parts of your design. This option is available only for Arria 10 and Cyclone 10 GX devices.
Allow Register Duplication	Allows the Compiler to duplicate registers to improve design performance. When you enable this option, the Compiler copies registers and moves some fan-out to this new node. This optimization improves routability and can reduce the total routing wire in nets with many fan-outs. If you disable this option, this disables optimizations that retime registers. This setting affects Analysis & Synthesis and the Fitter. This option is available only for Arria 10 and Cyclone 10 GX devices.
Allow Register Merging	Allows the Compiler to remove registers that are identical to other registers in the design. When you enable this option, in cases where two registers generate the same logic, the Compiler deletes one register, and the remaining registers fan-out to the deleted register's destinations. This option is useful if you want to prevent the Compiler from removing intentional use of duplicate registers. If you disable register merging, the Compiler disables optimizations that retime registers. This setting affects Analysis & Synthesis and the Fitter.

3.2. Applying Netlist Optimizations

The improvement in performance when using netlist optimizations is design dependent. If you have restructured your design to balance critical path delays, netlist optimizations might yield minimal improvement in performance.

You may have to experiment with available options to see which combination of settings works best for a particular design. Refer to the messages in the compilation report to see the magnitude of improvement with each option, and to help you decide whether you should turn on a given option or specific effort level.

Turning on more netlist optimization options can result in more changes to the node names in the design; bear this in mind if you are using a verification flow, such as the Signal Tap Logic Analyzer or formal verification that requires fixed or known node names.

To find the best results, you can use the Quartus Prime Design Space Explorer II (DSE) to apply various sets of netlist optimization options.

Related Information

Optimize Settings with Design Space Explorer II on page 102

3.2.1. WYSIWYG Primitive Resynthesis

For designs synthesized with a third-party tool, the **Perform WYSIWYG primitive resynthesis** option allows you to apply optimizations to the synthesized netlist.

The **Perform WYSIWYG primitive resynthesis** option directs the Quartus Prime software to un-map the logic elements (LEs) in an atom netlist to logic gates, and then re-map the gates back to Intel-specific primitives. Third-party synthesis tools generate either an `.edf` or `.vqm` atom netlist file using Intel-specific primitives. When you turn on the **Perform WYSIWYG primitive resynthesis** option, the Quartus Prime software uses device-specific techniques during the re-mapping process. This feature re-maps the design using the **Optimization Technique** specified for your project (**Speed**, **Area**, or **Balanced**).

The **Perform WYSIWYG primitive resynthesis** option unmaps and remaps only logic cells, also referred to as LCELL or LE primitives, and regular I/O primitives (which may contain registers). Double data rate (DDR) I/O primitives, memory primitives, digital signal processing (DSP) primitives, and logic cells in carry chains are not remapped. This process does not process logic specified in an encrypted `.vqm` file or an `.edf` file, such as third-party intellectual property (IP).

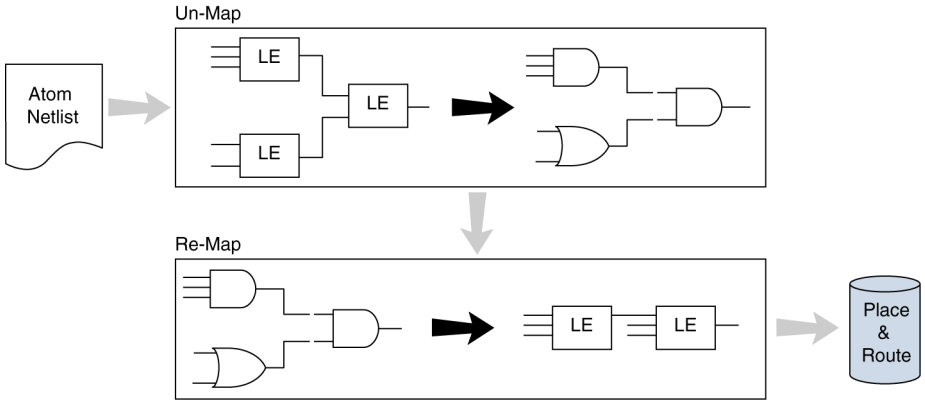
The **Perform WYSIWYG primitive resynthesis** option can change node names in the `.vqm` file or `.edf` file from your third-party synthesis tool, because the primitives in the atom netlist are broken apart and then re-mapped by the Quartus Prime software. The re-mapping process removes duplicate registers. Registers that are not removed retain the same name after re-mapping.

Any nodes or entities that have the **Netlist Optimizations** logic option set to **Never Allow** are not affected during WYSIWYG primitive resynthesis. You can use the Assignment Editor to apply the **Netlist Optimizations** logic option. This option disables WYSIWYG resynthesis for parts of your design.

Note: Primitive node names are specified during synthesis. When netlist optimizations are applied, node names might change because primitives are created and removed. HDL attributes applied to preserve logic in third-party synthesis tools cannot be maintained because those attributes are not written into the atom netlist, which the Quartus Prime software reads.

If you use the Quartus Prime software to synthesize your design, you can use the **Preserve Register (preserve)** and **Keep Combinational Logic (keep)** attributes to maintain certain nodes in the design.

Figure 19. Quartus Prime Flow for WYSIWYG Primitive Resynthesis



3.3. Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus Prime Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp
```

You can specify many of the options described in this section on either an instance or global level, or both.

Use the following Tcl command to make a global assignment:

```
set_global_assignment -name <QSF variable name> <value>
```

Use the following Tcl command to make an instance assignment:

```
set_instance_assignment -name <QSF variable name> <value> -to <instance name>
```

Related Information

Quartus Prime Pro Edition User Guide: Scripting

3.3.1. Synthesis Netlist Optimizations

The project `.qsf` file preserves the settings that you specify in the GUI. Alternatively, you can edit the `.qsf` directly. The `.qsf` file supports the following synthesis netlist optimization commands. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 10. Synthesis Netlist Optimizations and Associated Settings

Setting Name	Quartus Prime Settings File Variable Name	Values	Type
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance
Optimization Mode	OPTIMIZATION_MODE	BALANCED, HIGH PERFORMANCE EFFORT, HIGH PERFORMANCE EFFORT WITH MAXIMUM PLACEMENT EFFORT, HIGH PERFORMANCE WITH AGGRESSIVE POWER EFFORT, SUPERIOR PERFORMANCE, SUPERIOR PERFORMANCE WITH MAXIMUM PLACEMENT EFFORT, AGGRESSIVE AREA, HIGH PLACEMENT ROUTABILITY EFFORT, HIGH PACKING ROUTABILITY EFFORT, OPTIMIZE NETLIST FOR ROUTABILITY, AGGRESSIVE POWER,	Global, Instance
Power-Up Don't Care	ALLOW_POWER_UP_DONT_CARE	ON, OFF	Global

3.3.2. Physical Synthesis Optimizations

The project `.qsf` file preserves the settings that you specify in the GUI. Alternatively, you can edit the `.qsf` directly. The `.qsf` file supports the following synthesis netlist optimization commands. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 11. Physical Synthesis Optimizations and Associated Settings

Setting Name	Quartus Prime Settings File Variable Name	Values	Type
Advanced Physical Synthesis	ADVANCED_PHYSICAL_SYNTHESIS	ON, OFF	Global

3.4. Netlist Optimizations and Physical Synthesis Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2022.01.07	21.4	• Revised *Disabling or Enabling Physical Synthesis Optimization* topic for default state. • Revised *Physical Synthesis Options* for device support limitations. • Corrected syntax error in *Scripting Support* topic. • Revised *Synthesis Netlist Optimizations and Associated Settings* topic for latest options.
2019.04.24	18.1	Updated example in "Netlist Optimizations and Physical Synthesis" topic.
2019.04.18	18.1	Clarified wording in "Netlist Optimizations and Physical Synthesis" topic.
2018.09.24	18.1	Removed reference to unsupported CASCADE buffer from "Optimize IOC Register Placement for Timing Logic Option" topic.
2018.05.07	18.0	Removed topic: *Isolating a Partition Netlist*.
2017.11.06	17.1	• Removed reference to .vqm files • Added topic: *Isolating a Partition Netlist*.
2016.10.31	16.1	• Implemented Intel rebranding. • Updated physical synthesis options and procedure.
2016.05.02	16.0	• Removed information about deprecated physical synthesis options.
2015.11.02	15.1	• Changed instances of *Quartus II* to *Quartus Prime*. • Added Physical Synthesis.
2014.12.15	14.1	• Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Synthesis Optimizations Settings to Compiler Settings. • Updated DSE II content.
June 2014	14.0	Updated format.
November 2013	13.1	Removed HardCopy device information.
June 2012	12.0	Removed survey link.
November 2011	10.0.2	Template update.
December 2010	10.0	Template update.
July 2010	10.0	• Added links to Quartus Prime Help in several sections. • Removed Referenced Documents section. • Reformatted Document Revision History
November 2009	9.1	• Added information to “Physical Synthesis for Registers—Register Retiming” • Added information to “Applying Netlist Optimization Options” • Made minor editorial updates

continued...

Document Version	Quartus Prime Version	Changes
March 2009	9.0	• Was chapter 11 in the 8.1.0 release. • Updated the "Physical Synthesis for Registers—Register Retiming" and "Physical Synthesis Options for Fitting" • Updated "Performing Physical Synthesis Optimizations" • Deleted Gate-Level Register Retiming section. • Updated the referenced documents
November 2008	8.1	Changed to 8½" × 11" page size. No change to content.
May 2008	8.0	• Updated "Physical Synthesis Optimizations for Performance on page 11-9 • Added Physical Synthesis Options for Fitting on page 11-16

4. Area Optimization

This chapter describes techniques for efficient use of device resources.

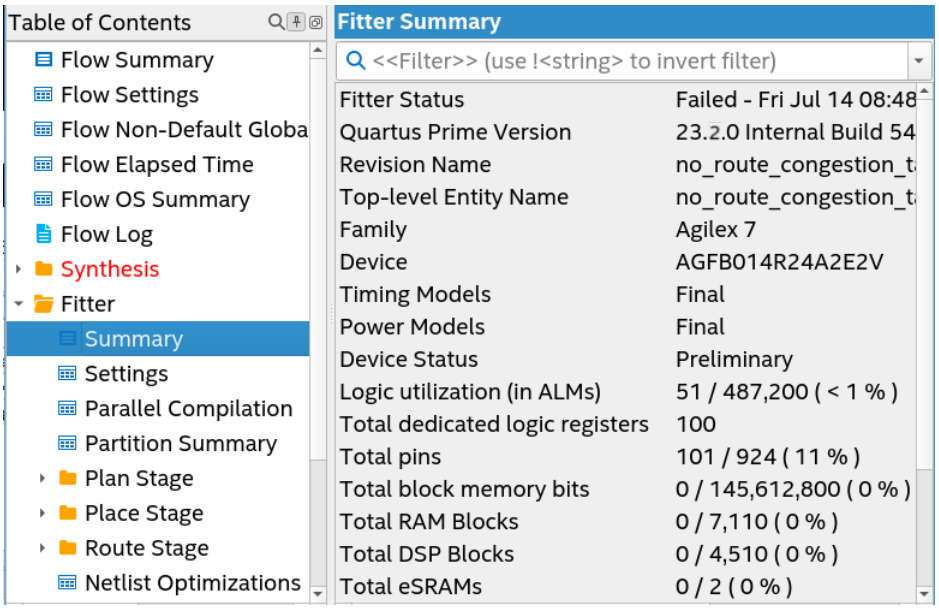
4.1. Resource Utilization Information

Determining device utilization provides useful information regardless of whether the design achieved a successful fit. If the compilation results in a no-fit error, resource utilization information helps to analyze the fitting problems in the design. If the fitting is successful, this information allows you to determine if design changes introduce fitting difficulties. Additionally, you can determine the impact of the resource utilization in the timing performance. The Compilation Report provides information about resource usage.

4.1.1. Flow Summary Report

The **Flow Summary** section of the compilation report indicates whether the design exceeds the available device resources, and reports resource utilization, including pins, memory bits, DSP blocks, and PLLs.

Figure 20. Flow Summary Report



The Fitter can spread logic throughout the device, which may lead to higher overall utilization. As the device fills up, the Fitter automatically searches for logic functions with common inputs to place in one ALM. The number of packed registers also

increases. Therefore, a design that has high overall utilization might still have space for extra logic if the logic and registers can be packed together more tightly. In those cases, you can benefit by a report that provides more details.

4.1.2. Fitter Reports

The Fitter generates detailed reports for each stage of place and route. The **Fitter** section of the Compilation Report includes reports detailing the Fitter's use of device resources.

The **Fitter Resource Usage Summary** report summarizes how the Fitter utilizes logic resources of the target device when implementing your design, such as the number of bits in each type of memory block. This report also summarizes the usage of global clocks, PLLs, DSP blocks, and other device-specific resources.

Related Information

Quartus Prime Pro Edition User Guide: Design Compilation

4.1.2.1. Route Stage Reports

The Route stage reports (**Compilation Report ➤ Fitter ➤ Route Stage**) provide details about the various types of device resources that the Fitter allocates during routing. These details include reports on the following types of routing information:

- The type, number, and overall use percentage of each device resource
- Nets with the highest wire count
- Delay chain summary information
- Global wire utilization information
- The top congested hierarchies and nets

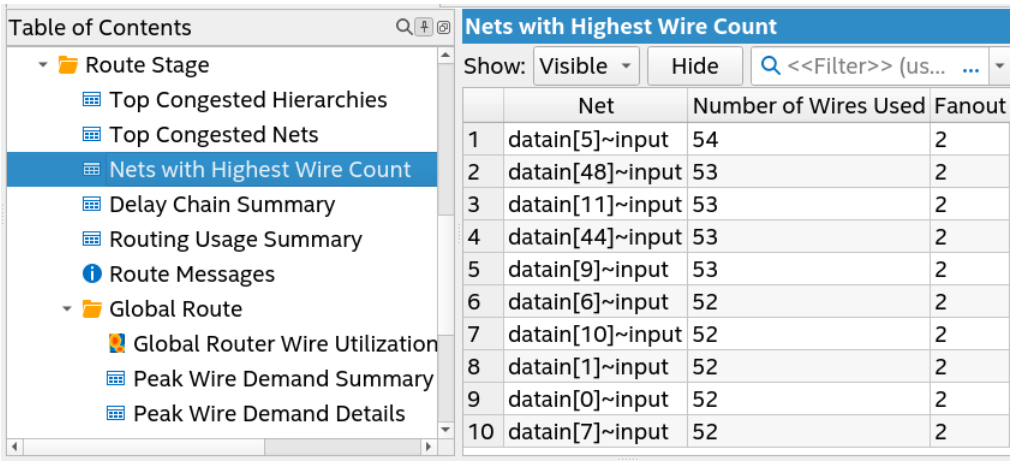
Figure 21. Example Routing Usage Summary

	Routing Resource Type	Usage
1	Block Input Mux Wrapbacks	0 / 516,600 (0 %)
2	Block Input Muxes	0 / 5,658,000 (0 %)
3	Block interconnects	0 / 6,625,600 (0 %)
4	C1 interconnects	0 / 2,769,200 (0 %)
5	C4 interconnects	0 / 2,640,400 (0 %)
6	C8 interconnects	0 / 264,040 (0 %)
7	DCM_muxes	1 / 824 (< 1 %)
8	DELAY_CHAINs	0 / 17,290 (0 %)
9	Direct links	0 / 6,625,600 (0 %)
10	HIO Buffers	0 / 45,920 (0 %)

4.1.2.1.1. Nets with Highest Wire Count Report

The Nets with Highest Wire Count report (**Route Stage ➤ Nets with Highest Wire Count**) lists in descending order the nets that use the highest number of wires in the design and their fan-out count. You can use this report to identify and evaluate the high fan-out nets in the design. The Nets with Highest Wire Count report generates whether or not the design routes successfully.

Figure 22. Example Nets with Highest Wire Count Report

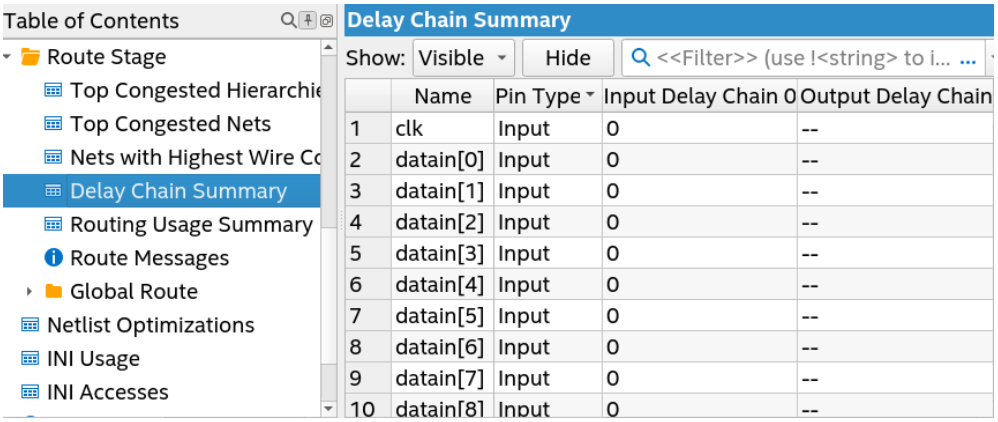


4.1.2.1.2. Delay Chain Summary Report

A delay chain is a series of LCELL or EXP primitives or I/O delay chains in the I/O block that you use to create an intentional delay or asynchronous pulse. A delay chain is generally unreliable because the best-case delay of an LCELL or EXP cannot be guaranteed. This delay chain configuration also increases the sensitivity of the design to operating conditions.

The Delay Chain Summary report (**Route Stage ➤ Delay Chain Summary**) summarizes information about the delay chains in your design. This report lists the node name and pin type in the chain. Delay chains appear in terms of their delay chain fan-out setting and actual delay in ps.

Figure 23. Example Delay Chain Summary Report (Truncated)



4.1.2.1.3. Top Congested Hierarchies and Nets Reports

If your design fails to route, you can use the Top Congested Hierarchies and Top Congested Nets reports to determine the most congested hierarchies and nets in the design. View these reports under **Compilation Report ➤ Fitter ➤ Route Stage**.

Use context menu commands to locate directly to the reported hierarchies and nets in the Text Editor, Assignment Editor, Pin Planner, Chip Planner, and other editors. Optimize your design in the reported areas to reduce the congestion and successfully route the design.

Figure 24. Example Top Congested Hierarchies Report (Truncated)

	Hierarchy	Number of Overused Nodes
1	ff_1[41]	6
2	ff_1[32]	6
3	ff_1[11]	5
4	ff_1[39]	4
5	ff_1[47]	3
6	ff_1[48]	3
7	ff_1[14]	3
8	ff_1[8]	3
9	ff_1[16]	3
10	ff_1[49]	3

Figure 25. Example Top Congested Nets Report (Truncated)

	Net	Number of Overused Nodes	Fanout
1	ff_1[41]	6	2
2	ff_1[32]	6	2
3	ff_1[11]	5	2
4	ff_1[39]	4	2
5	ff_1[8]	3	2

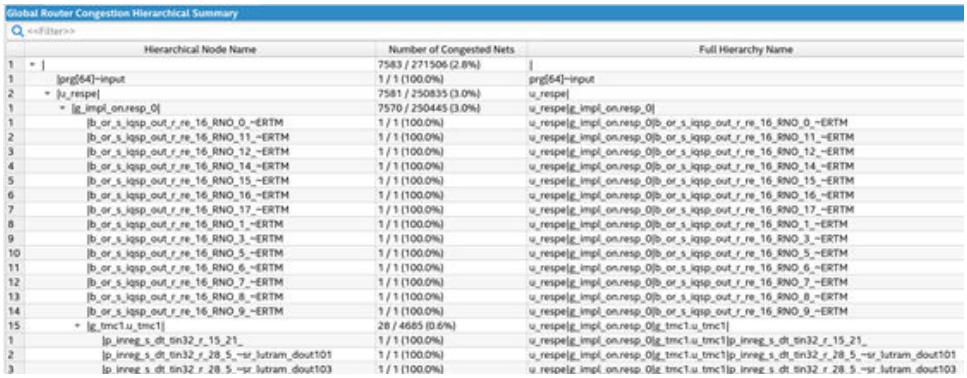
4.1.2.1.4. Global Route Reports

A global routing congested region is an area of the FPGA where short wire usage in a particular direction exceeds the capacity of that region. A congested net is a net that passes through a global routing congested region. The Global Route reports (**Compilation Report ➤ Fitter ➤ Route Stage ➤ Global Route**) show information about the congested nets in your design.

Figure 26. Example of the Global Router Congestion Hotspot Summary Report



Global Router Congestion Hierarchical Summary

	Hierarchical Node Name	Number of Congested Nets	Full Hierarchy Name
1	|	7583 / 271506 (2.8%)	|
1	|prg[64]~input	1 / 1 (100.0%)	prg[64]~input
2	|u_respe|	7581 / 250835 (3.0%)	u_respe|
1	|g_impl_on.resp_0|	7570 / 250445 (3.0%)	u_respe|g_impl_on.resp_0|
1	|b_or_s_iqsp_out_r_re_16_RNO_0_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_0_~ERTM
2	|b_or_s_iqsp_out_r_re_16_RNO_11_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_11_~ERTM
3	|b_or_s_iqsp_out_r_re_16_RNO_12_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_12_~ERTM
4	|b_or_s_iqsp_out_r_re_16_RNO_14_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_14_~ERTM
5	|b_or_s_iqsp_out_r_re_16_RNO_15_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_15_~ERTM
6	|b_or_s_iqsp_out_r_re_16_RNO_16_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_16_~ERTM
7	|b_or_s_iqsp_out_r_re_16_RNO_17_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_17_~ERTM
8	|b_or_s_iqsp_out_r_re_16_RNO_1_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_1_~ERTM
9	|b_or_s_iqsp_out_r_re_16_RNO_3_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_3_~ERTM
10	|b_or_s_iqsp_out_r_re_16_RNO_5_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_5_~ERTM
11	|b_or_s_iqsp_out_r_re_16_RNO_6_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_6_~ERTM
12	|b_or_s_iqsp_out_r_re_16_RNO_7_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_7_~ERTM
13	|b_or_s_iqsp_out_r_re_16_RNO_8_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_8_~ERTM
14	|b_or_s_iqsp_out_r_re_16_RNO_9_~ERTM	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|b_or_s_iqsp_out_r_re_16_RNO_9_~ERTM
15	|g_tmc1:u_tmc1|	28 / 4685 (0.6%)	u_respe|g_impl_on.resp_0|g_tmc1:u_tmc1|
1	|p_inreg_s_dt_tin32_r_15_21_	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|g_tmc1:u_tmc1|p_inreg_s_dt_tin32_r_15_21_
2	|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout101	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|g_tmc1:u_tmc1|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout101
3	|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout103	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|g_tmc1:u_tmc1|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout103

For example, the Global Router Congestion Hotspot Summary report shows congested net hotspots in your design organized by hierarchical node name. If the congested area is small, the Router may be successful in detouring around overused regions. However, if the congested area is large, routing may be unsuccessful. The exact threshold where the Fitter cannot route the design varies greatly by design characteristics.

Use the Global Router Congestion Hotspot Summary report to identify parts of your RTL code that are associated with routing congestion. The Global Router Wire Utilization Map shows the threshold and size of the largest congested region if the size of adjacent congested regions is below a threshold.

4.1.3. Design Assistant Recommendations

You can run the Design Assistant at various stages throughout the compilation process. Correcting Design Assistant rule violations improves the reliability, timing performance, and logic utilization of the design.

4.1.4. Analysis and Synthesis Reports

For designs synthesized with the Quartus Prime synthesis engine, you can see reports describing optimizations that occurred during compilation.

For example, in the **Analysis & Synthesis** section, **Optimization Results** folder, you can find a list of registers removed during synthesis. With this report you can estimate resource utilization for partial designs so you make sure that registers were not removed due to missing connections with other parts of the design.

Related Information

Quartus Prime Pro Edition User Guide: Design Recommendations

4.1.5. Compilation Messages

If the reports show resource usage lower than 100%, but the design does not fit, either resources are insufficient or the design contains invalid assignments. In either case, the Compiler generates a message in the **Processing** tab of the **Messages** window describing the problem. As resource utilization approaches 100%, the design becomes increasingly difficult to fit.

If the Fitter finishes unsuccessfully and runs much faster than on similar designs, a resource might be over-utilized, there might be an illegal location or timing assignment that is difficult or impossible to resolve.

If the Quartus Prime software takes too long to run when compared to similar designs, the Compiler may not be able to find a valid placement or route solution. In the Compilation Report, look for errors and warnings that indicate these types of problems.

Related Information

Viewing Messages

4.1.6. Chip Planner Visualization

The Chip Planner can help you find areas of the device that have routing congestion for specific types of routing resources. If you find areas with very high congestion, analyze the cause of the congestion. Issues such as high fan-out nets not using global resources, an improperly chosen optimization goal (speed versus area), very restrictive floorplan assignments, or the coding style can cause routing congestion. After you identify the cause, modify the source or settings to reduce routing congestion.

Related Information

Viewing Routing Congestion in Chip Planner on page 151

4.2. Optimizing Resource Utilization

The following lists the stages after design analysis:

1. Optimize resource utilization—Ensure that you have already set the basic constraints
2. I/O timing optimization—Optimize I/O timing after you optimize resource utilization and your design fits in the desired target device
3. Register-to-register timing optimization

Related Information

- Design Optimization Overview on page 6
- Timing Closure and Optimization on page 65

4.2.1. Resource Utilization Issues Overview

Resource utilization issues can be divided into three categories:

- Issues relating to *I/O pin utilization or placement*, including dedicated I/O blocks such as PLLs or LVDS transceivers.
- Issues relating to *logic utilization or placement*, including logic cells containing registers and LUTs as well as dedicated logic, such as memory blocks and DSP blocks.
- Issues relating to *routing*.

4.2.2. I/O Pin Utilization or Placement

Resolve I/O resource problems with these guidelines.

4.2.2.1. Guideline: Modify Pin Assignments or Choose a Larger Package

If a design that has pin assignments fails to fit, compile the design without the pin assignments to determine whether a fit is possible for the design in the specified device and package. You can use this approach if an Quartus Prime error message indicates fitting problems due to pin assignments.

If the design fits when all pin assignments are ignored or when several pin assignments are ignored or moved, you might have to modify the pin assignments for the design or select a larger package.

If the design fails to fit because insufficient I/Os pins are available, a larger device package (which can be the same device density) that has more available user I/O pins can result in a successful fit.

Related Information

Quartus Prime Pro Edition User Guide: Design Constraints

4.2.3. Logic Utilization or Placement

Resolve logic resource problems, including logic cells containing registers and LUTs, as well as dedicated logic such as memory blocks and DSP blocks, with these guidelines.

4.2.3.1. Guideline: Optimize Source Code

If your design does not fit because of logic utilization, then evaluate and modify the design at the source. The Design Assistant reports can help you to identify source code optimizations.

You can often improve logic significantly by making design-specific changes to your source code. This is typically the most effective technique for improving the quality of your results.

If your design does not fit into available logic elements (LEs) or ALMs, but you have unused memory or DSP blocks, check if you have code blocks in your design that describe memory or DSP functions that are not being inferred and placed in dedicated logic. You might be able to modify your source code to allow these functions to be placed into dedicated memory or DSP resources in the target device.

Ensure that your state machines are recognized as state machine logic and optimized appropriately in your synthesis tool. State machines that are recognized are generally optimized better than if the synthesis tool treats them as generic logic. In the Quartus Prime software, you can check for the State Machine report under **Analysis & Synthesis** in the Compilation Report. This report provides details, including the state encoding for each state machine that was recognized during compilation. If your state machine is not being recognized, you might have to change your source code to enable it to be recognized.

4.2.3.2. Guideline: Optimize Synthesis for Area, Not Speed

If the Fitter cannot resolve a design due to limitations in logic resources, resynthesize the design to improve the area utilization.

First, ensure that the device and timing constraints are set correctly in the synthesis tool. Particularly when area utilization of the design is a concern, ensure that you do not over-constrain the timing requirements for the design. Synthesis tools try to meet the specified requirements, which can result in higher device resource usage if the constraints are too aggressive.

If resource utilization is an important concern, you can optimize for area instead of speed.

- If you are using Quartus Prime synthesis, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)** and select **Balanced** or **Area** for the **Optimization Technique**.
- The **Aggressive Area Optimization Mode** optimizes for area at the cost of performance.
- If you want to reduce area for specific modules in the design using the **Area** or **Speed** setting while leaving the default **Optimization Technique** setting at **Balanced**, use the Assignment Editor.
- In some synthesis tools, not specifying an f_{MAX} requirement can result in less resource utilization.

Optimizing for area or speed can affect the register-to-register timing performance.

Note: In the Quartus Prime software, the **Balanced** setting typically produces utilization results that are very similar to those produced by the **Area** setting, with better performance results. The **Area** setting can give better results in some cases.

The Quartus Prime software provides additional attributes and options that can help improve the quality of the synthesis results.

Related Information

Optimization Mode

4.2.3.3. Guideline: Restructure Multiplexers

Multiplexers form a large portion of the logic utilization in many FPGA designs. By optimizing your multiplexed logic, you can achieve a more efficient implementation in your Intel device.

Related Information

Restructure Multiplexers logic option
For more information about the Restructure Multiplexers option

4.2.3.4. Guideline: Perform WYSIWYG Primitive Resynthesis with Balanced or Area Setting

The **Perform WYSIWYG Primitive Resynthesis** logic option specifies whether to perform WYSIWYG primitive resynthesis during synthesis. This option uses the setting specified in the **Optimization Technique** logic option. The **Perform WYSIWYG Primitive Resynthesis** logic option is useful for resynthesizing some or all of the

WYSIWYG primitives in your design for better area or performance. However, WYSIWYG primitive resynthesis can be done only when you use third-party synthesis tools.

Note: The **Balanced** setting typically produces utilization results that are very similar to the **Area** setting with better performance results. The **Area** setting can give better results in some cases. Performing WYSIWYG resynthesis for area in this way typically reduces register-to-register timing performance.

Related Information

Perform WYSIWYG Primitive Resynthesis logic option
For information about this logic option

4.2.3.5. Guideline: Use Register Packing

The **Auto Packed Registers** option implements the functions of two elements into one logic element by combining the register of one element, in which only the register is used with the LUT of another element, in which only the LUT is used.

Remember: DSP register packing is not always possible. For a list of conditions that prevent register packing, refer to the "Fixed Point DSP Register Packing Summary and Fixed Point DSP Register Packing Details" section of *Fitter Feature Specific Report* in the Quartus Prime Pro Edition help.

DSP Register Packing Entity Assignment

In addition, you can control DSP register packing at the entity level by specifying the **DSP Register Packing** entity assignment in the Assignment Editor, or with the corresponding `DSP_REGISTER_PACKING` assignment in the project `.qsf`. **DSP Register Packing** specifies how aggressively the Fitter optimizes DSP performance by automatically packing registers into the internal registers of the specified DSP blocks. With the default **Balanced** setting, the Fitter packs registers into the specified DSP blocks that improve timing. With **Always** enabled, the Fitter aggressively pack registers into the specified DSP blocks, unless your constraints or other legality restrictions prevent packing. With **Disable** enabled, registers do not pack into the specified DSP blocks. The following is the equivalent `.qsf` assignment:

```
set_instance_assignment -name DSP_REGISTER_PACKING -to \
<to> -entity <name> <value>
```

DSP_REGISTER_PACKING_LEVEL Entity Assignment

In addition, you can enter the `DSP_REGISTER_PACKING_LEVEL` entity assignment directly in the project `.qsf` to specify the maximum number of register stages desired for a specific DSP. `DSP_REGISTER_PACKING_LEVEL` specifies the maximum number of registers that you want to pack in the specified DSP instance. The following are `DSP_REGISTER_PACKING_LEVEL` setting values:

- `0`—equivalent to disabling DSP register packing operation of the DSP.
- `1`—the Fitter tries to pack one layer of registers from the DSP's input side.
- `2`—the Fitter tries to add an additional layer of registers from the DSP's output side.
- `3` or `4`—the Fitter tries to add one or two layers of the pipeline registers from the input side.

If the Compiler cannot implement the packing level you specify, the Compiler issues a warning message indicating that the assignment is not respected. the Fixed Point DSP Register Packing Details report also describes the reasons the packing level cannot be met. The following is the equivalent `.qsf` assignment:

```
set_instance_assignment -name DSP_REGISTER_PACKING_LEVEL -to \
<to> -entity <entity name> <value>
```

Fixed Point DSP Register Packing Summary Report and Fixed Point DSP Register Packing Details Report

After running the Compiler's **Plan** stage, the Compilation Report includes the Fixed Point DSP Register Packing Summary report, and the Fixed Point DSP Register Packing Details report. These reports provide information about the use of DSP blocks in your design, including DSP register packing data. The summary report lists how many DSP blocks are fully registered, partially registered, or unregistered.

The Fixed Point DSP Register Packing Details report also indicates the names of the registers packed into register banks, the register usage (fully registered, partially registered, or unregistered), and the reasons preventing any register packing. Viewing these register name details in the report allows you to readily identify registers for packing assignments.

  For details about reason preventing register packing

4.2.3.6. Guideline: Remove Fitter Constraints

A design with conflicting constraints or constraints that are difficult to meet may not fit in the targeted device. For example, a design might fail to fit if the location or Logic Lock assignments are too strict and not enough routing resources are available on the device.

To resolve routing congestion caused by restrictive location constraints or Logic Lock region assignments, use the **Routing Congestion** task in the Chip Planner to locate routing problems in the floorplan, then remove any internal location or Logic Lock region assignments in that area. If your design still does not fit, the design is over-constrained. To correct the problem, remove all location and Logic Lock assignments and run successive compilations, incrementally constraining the design before each compilation. You can delete specific location assignments in the Assignment Editor or the Chip Planner. To remove Logic Lock assignments in the Chip Planner, in the Logic Lock Regions Window, or on the Assignments menu, click **Remove Assignments.** Turn on the assignment categories you want to remove from the design in the **Available assignment categories** list.

Related Information

Analyzing and Optimizing the Design Floorplan on page 142

4.2.3.7. Guideline: Flatten the Hierarchy During Synthesis

Synthesis tools typically provide the option of preserving hierarchical boundaries, which can be useful for verification or other purposes. However, the Quartus Prime software optimizes across hierarchical boundaries so as to perform the most logic minimization, which can reduce area in a design with no design partitions.

4.2.3.8. Guideline: Re-target Memory Blocks

If the Fitter cannot resolve a design due to memory resource limitations, the design may require a type of memory that the device does not have.

For memory blocks created with the Parameter Editor, edit the RAM block type to target a new memory block size.

The Compiler can also infer ROM and RAM memory blocks from the HDL code, and the synthesis engine can place large shift registers into memory blocks by inferring the Shift register (RAM-based) IP core. When you turn off this inference in the synthesis tool, the synthesis engine places the memory or shift registers in logic instead of memory blocks. Also, turning off this inference prevents registers from being moved into RAM, improving timing performance,

Depending on the synthesis tool, you can also set the RAM block type for inferred memory blocks. In Quartus Prime synthesis, set the **ramstyle** attribute to the desired memory type for the inferred RAM blocks. Alternatively, set the option to **logic** to implement the memory block in standard logic instead of a memory block.

Review the Resource Utilization by Entity report in the report file to determine whether there is an unusually high register count in any of the modules corresponding with an unexpectedly low RAM block count. Some coding styles prevent the Quartus Prime software from inferring RAM blocks from the source code because of the blocks' architectural implementation, forcing the software to implement the logic in flip-flops.

For example, an asynchronous reset on a register bank might make the register bank incompatible with the RAM blocks in the device architecture, so Compiler implements the register bank in flip-flops. It is often possible to move a large register bank into RAM by slight modification of associated logic.

Using the appropriate memory can also help reduce resource use. For example, a shallow but wider memory may be more suitable for MLABs, rather than for M20K memory blocks.

4.2.3.9. Guideline: Use Physical Synthesis Options to Reduce Area

The physical synthesis options available at **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)** help you decrease resource usage. When you enable physical synthesis, the Quartus Prime software makes placement-specific changes to the netlist that reduce resource utilization for a specific Intel device.

Note: Physical synthesis increases compilation time. To reduce the impact on compilation time, you can apply physical synthesis options to specific instances.

Related Information

Advanced Fitter Settings Dialog Box

4.2.3.10. Guideline: Retarget or Balance DSP Blocks

A design might not fit because it requires more DSP blocks than the target FPGA device has available.

You can implement all DSP block functions with logic cells, so you can retarget some of the DSP blocks to logic to obtain a fit.

If the DSP function was created with the parameter editor, open the parameter editor and edit the function so it targets logic cells instead of DSP blocks. The Quartus Prime software uses the `DEDICATED_MULTIPLIER_CIRCUITRY` IP core parameter to control the implementation.

DSP blocks also can be inferred from your HDL code for multipliers, multiply-adders, and multiply-accumulators. You can turn off this inference in your synthesis tool. When you are using Quartus Prime synthesis, you can disable inference by turning off the **Auto DSP Block Replacement** logic option for your entire project. Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)**. Turn off **Auto DSP Block Replacement**. Alternatively, you can disable the option for a specific block with the Assignment Editor.

The Quartus Prime software also offers the **DSP Block Balancing** logic option, which implements DSP block elements in logic cells or in different DSP block modes. The default **Auto** setting allows DSP block balancing to convert the DSP block slices automatically as appropriate to minimize the area and maximize the speed of the design. You can use other settings for a specific node or entity, or on a project-wide basis, to control how the Quartus Prime software converts DSP functions into logic cells and DSP blocks. Using any value other than **Auto** or **Off** overrides the `DEDICATED_MULTIPLIER_CIRCUITRY` parameter used in IP core variations.

For designs with large number of low-precision arithmetic operations, such as additions and multiplications, you can enable fractal synthesis optimizations. Fractal synthesis optimizations are useful for high-throughput, arithmetic-intensive designs that exceed all available DSP resources. These optimizations are beneficial in designs with large numbers of low-precision arithmetic operations, such as additions and multiplications.

Related Information

Fractal Synthesis Optimizations, Quartus Prime Pro Edition User Guide: Design Compilation

4.2.3.11. Guideline: Use a Larger Device

If a successful fit cannot be achieved because of a shortage of routing resources, you might require a larger device.

4.2.3.12. Guideline: Reduce Global Signal Congestion

For Stratix 10 and Arria 10 devices, you can refer to the generated Global Signal Visualization report to see global signal routing and clock sector utilization in an interactive heat map.

The presence of too many signals in a clock sector can result in congestion and routing failures in the Fitter's place stage. Use the Global Signal Visualization Report to debug global signal routing congestion and global signal placement and routing failures.

The interactive heat map shows the number of signals in use for a given clock sector. If these global signals are clocks, use clock region assignments to move clocks away from the affected clock sectors.

4.2.3.13. Guideline: Report Pipelining Information

Pipelining the design can be useful for providing resources for retiming and improving performance. However, excessive pipelining can unnecessarily consume area. Use the report_pipeline function to identify areas in the design with excess pipelining.

Related Information

Quartus Prime Pro Edition User Guide: Design Optimization

4.2.4. Routing

Resolve routing resource problems with these guidelines.

4.2.4.1. Guideline: Set Auto Packed Registers to Sparse or Sparse Auto

The **Auto Packed Registers** option reduces LE or ALM count in a design. You can set this option by clicking **Assignment ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**.

Related Information

Auto Packed Registers logic option

4.2.4.2. Guideline: Set Fitter Aggressive Routability Optimizations to Always

The **Fitter Aggressive Routability Optimization** option is useful if your design does not fit due to excessive routing wire utilization.

If there is a significant imbalance between placement and routing time (during the first fitting attempt), it might be because of high wire utilization. Turning on the **Fitter Aggressive Routability Optimizations** option can reduce your compilation time.

On average, this option can save up to 6% wire utilization, but can also reduce performance by up to 4%, depending on the device.

Related Information

Fitter Aggressive Routability Optimizations logic option

4.2.4.3. Guideline: Increase Router Effort Multiplier

The Router Effort Multiplier controls how quickly the router tries to find a valid solution. The default value is 1.0 and legal values must be greater than 0.

- Numbers higher than 1 help designs that are difficult to route by increasing the routing effort.
- Numbers closer to 0 (for example, 0.1) can reduce router runtime, but usually reduce routing quality slightly.

Experimental evidence shows that a multiplier of 3.0 reduces overall wire usage by approximately 2%. Using a Router Effort Multiplier higher than the default value can benefit designs with complex datapaths with more than five levels of logic. However, congestion in a design is primarily due to placement, and increasing the Router Effort Multiplier does not necessarily reduce congestion.

Note: Any Router Effort Multiplier value greater than 4 only increases by 10% for every additional 1. For example, a value of 10 is actually 4.6.

4.2.4.4. Guideline: Remove Fitter Constraints

A design with conflicting constraints or constraints that are difficult to meet may not fit in the targeted device. For example, a design might fail to fit if the location or Logic Lock assignments are too strict and not enough routing resources are available on the device.

To resolve routing congestion caused by restrictive location constraints or Logic Lock region assignments, use the **Routing Congestion** task in the Chip Planner to locate routing problems in the floorplan, then remove any internal location or Logic Lock region assignments in that area. If your design still does not fit, the design is over-constrained. To correct the problem, remove all location and Logic Lock assignments and run successive compilations, incrementally constraining the design before each compilation. You can delete specific location assignments in the Assignment Editor or the Chip Planner. To remove Logic Lock assignments in the Chip Planner, in the Logic Lock Regions Window, or on the Assignments menu, click **Remove Assignments.** Turn on the assignment categories you want to remove from the design in the **Available assignment categories** list.

Related Information

Analyzing and Optimizing the Design Floorplan on page 142

4.2.4.5. Guideline: Optimize Synthesis for Routability

You can specify Compiler optimization modes that optimize for routability over speed.

If resource utilization is an important concern, you can optimize for routability rather than speed.

The High-Placement Routability Effort, **High Packing Routability Effort**, and **Optimize Netlist for Routability Optimization** modes apply optimizations that improve routability of the design.

The Quartus Prime software provides additional attributes and options that can help improve the quality of your synthesis results.

Related Information

Optimization Mode

4.2.4.6. Guideline: Optimize Source Code

If your design does not fit because of routing problems and the methods described in the preceding sections do not sufficiently improve the routability of the design, you can modify the design at the source to achieve the desired results.

You can often improve results significantly by making design-specific changes to your source code, such as duplicating logic or changing the connections between blocks that require significant routing resources.

You can use the Design Assistant to help you identify areas in the design that can benefit from optimization. For example, the following Design Assistant rules identify registers in the design with high tension span, for which register duplication simplifies place and route.

You can also view the Global Router Wire Utilization Map report to identify instances and nets that utilize many global wire resources.

4.2.4.7. Guideline: Use a Larger Device

If a successful fit cannot be achieved because of a shortage of routing resources, you might require a larger device.

4.3. Scripting Support

You can run procedures and assign settings described in this chapter in a Tcl script. You can also run procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus Prime command-line and Tcl API Help browser.

1. To run the Help browser, type the following command at the command prompt:

   ```
   quartus_sh --qhelp
   ```

   You can specify many of the options described in this section either in an instance, or at a global level, or both.
2. Use the following Tcl command to make a global assignment:

   ```
   set_global_assignment -name <QSF variable name> <value>
   ```
3. Use the following Tcl command to make an instance assignment:

   ```
   set_instance_assignment -name <QSF variable name> <value> -to <instance name>
   ```

Note: If the <*value*> field includes spaces (for example, 'Standard Fit'), you must enclose the value in straight double quotation marks.

4.3.1. Initial Compilation Settings

Use the Quartus Prime Settings File (`.qsf`) variable name in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 12. Advanced Compilation Settings

Setting Name	.qsf File Variable Name	Values	Type
Placement Effort Multiplier	PLACEMENT_EFFORT_MULTIPLIER	Any positive, non-zero value	Global
Router Effort Multiplier	ROUTER_EFFORT_MULTIPLIER	Any positive, non-zero value	Global
Router Timing Optimization level	ROUTER_TIMING_OPTIMIZATION_LEVEL	NORMAL, MINIMUM, MAXIMUM	Global
Final Placement Optimization	FINAL_PLACEMENT_OPTIMIZATION	ALWAYS, AUTOMATICALLY, NEVER	Global

4.3.2. Resource Utilization Optimization Techniques

This table lists QSF assignments and applicable values for Resource Utilization Optimization settings:

Table 13. Resource Utilization Optimization Settings

Setting Name	.qsf File Variable Name	Values	Type
Auto Packed Registers	QII_AUTO_PACKED_REGISTERS	AUTO, OFF, NORMAL, MINIMIZE AREA, MINIMIZE AREA WITH CHAINS,SPARSE, SPARSE AUTO	Global, Instance
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance
Optimization Technique	OPTIMIZATION_TECHNIQUE	AREA, SPEED, BALANCED	Global, Instance
Speed Optimization Technique for Clock Domains	SYNTH_CRITICAL_CLOCK	ON, OFF	Instance
State Machine Encoding	STATE_MACHINE_PROCESSING	AUTO, ONE-HOT, GRAY, JOHNSON, MINIMAL BITS, ONE-HOT, SEQUENTIAL, USER-ENCODE	Global, Instance
Auto RAM Replacement	AUTO_RAM_RECOGNITION	ON, OFF	Global, Instance
Auto ROM Replacement	AUTO_ROM_RECOGNITION	ON, OFF	Global, Instance

continued...

Setting Name	.qsf File Variable Name	Values	Type
Auto Shift Register Replacement	AUTO_SHIFT_REGISTER_RECOGNITION	ON, OFF	Global, Instance
Auto Block Replacement	AUTO_DSP_RECOGNITION	ON, OFF	Global, Instance
Number of Processors for Parallel Compilation	NUM_PARALLEL_PROCESSORS	Integer between 1 and 16 inclusive, or ALL	Global

4.4. Area Optimization Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2023.10.02	23.3	• Updated *Guideline: Use Register Packing* to include link to help topic with list of reasons that prevent register packing.
2023.07.24	23.2	• Added new *Route Stage Reports* section to describe latest routing reports to alleviate routing congestion.
2023.04.03	23.1	• Revised *Guideline: Use Register Packing* to describe latest changes for DSP Register Packing and DSP_REGISTER_PACKING_LEVEL entity assignments and reporting.
2022.01.07	21.4	• Corrected syntax error in *Scripting Support* topic. • Added link to *Fitter Reports* topic. • Added new *Design Assistant Recommendations* topic. • Revised *Compilation Messages* topic. • Added *Chip Planner Visualization* topic. • Added reference to Design Assistant to *Guideline: Optimize Source Code* topic. • Revised *Guideline: Optimize Synthesis for Area, Not Speed* topic to mention Aggressive Area Optimization Mode. • Revised *Guideline: Optimize Synthesis for Area, Not Speed* topic to mention Aggressive Area Optimization Mode and remove Speed Optimization Technique for Clock Domains reference. • Revised *Guideline: Retarget Memory Blocks* topic to mention use of appropriate embedded memory IP. • Revised *Guideline: Retarget or Balance DSP Blocks* topic to mention use of fractal synthesis. • Added *Guideline: Report Pipelining Information* topic. • Added reference to Global Router Wire Utilization Map report to *Guideline: Optimize Source Code* topic. • Removed references to obsolete Timing Optimization Advisor.
2018.10.18	18.1	• Corrected broken link to Optimization Modes Help topic.
2018.09.24	18.1	• Divided topic: *Resource Utilization* into topics: *Resource Utilization Information*, *Flow Summary Report*, *Fitter Reports*, *Analysis and Synthesis Reports*, and *Compilation Messages*.
2018.07.03	18.0	Fixed typo and added links in topic *Guideline: Retarget Memory Blocks*.
2017.05.08	17.0	• Removed information about deprecated Integrated Synthesis • Revised topics: *Resolving Resource Utilization Issues*, *Guideline: Optimize Synthesis for Area, Not Speed*
2016.10.31	16.1	• Implemented Intel rebranding.

continued...

Document Version	Quartus Prime Version	Changes
2016.05.02	16.0	• Removed information about deprecated physical synthesis options.
2015.11.02	15.1	Changed instances of *Quartus II* to *Intel Quartus Prime*.
2014.12.15	14.1	Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Synthesis Optimizations to Compiler Settings.
June 2014	14.0	• Removed Cyclone III and Stratix III devices references. • Removed Macrocell-Based CPLDs related information. • Updated template.
May 2013	13.0	Initial release.

5. Timing Closure and Optimization

This chapter describes techniques to improve timing performance when designing for Intel FPGA devices. The application of techniques varies between designs and target FPGA device. Applying each technique does not improve results in all cases.

The default settings and options in the Quartus Prime software provide the most balanced trade-off between compilation time, resource utilization, and timing performance. You can then adjust these settings to determine whether a different mix of settings might provide better results for your design.

5.1. Optimize Multi Corner Timing

Process variations and changes in operating conditions can result in path delays that are significantly smaller than those in the slow corner timing model. As a consequence, the design can present hold time violations on those paths, and in rare cases, additional setup time violations.

In addition, designs targeting newer device families (with smaller process geometry) do not always present the slowest circuit performance at the highest operating temperature. The temperature at which the circuit is slowest depends on the selected device, the design, and the compilation results. The Quartus Prime software manages this new dependency by providing newer device families with three different timing corners—Slow 85°C corner, Slow 0°C corner, and Fast 0°C corner. For other device families, two timing corners are available—Fast 0°C and Slow 85°C corner.

The **Optimize multi-corner timing** option directs the Fitter to meet timing requirements at all process corners and operating conditions. The resulting design implementation is more robust across process, temperature, and voltage variations. This option is on by default, and increases compilation time by approximately 10%.

When this option is off, the Fitter optimizes designs considering only slow-corner delays from the slow-corner timing model (slowest manufactured device for a given speed grade, operating in low-voltage conditions).

5.2. Optimize Critical Paths

Critical paths are timing paths in your design that have a negative slack and may require optimization. These timing paths can span from device I/Os to internal registers, registers to registers, or from registers to device I/Os.

The slack of a path determines its criticality; slack appears in the timing analysis report, which you can generate using the Timing Analyzer.

Design analysis for timing closure is a fundamental requirement for optimal performance in highly complex designs. The analytical capability of the Chip Planner helps you close timing on complex designs.

Related Information

Critical Path Delay Reduction Trade-Offs on page 11

5.2.1. Viewing Critical Paths

Viewing critical paths in the Chip Planner shows why a specific path is failing. You can see if any modification in the placement can reduce the negative slack. To display paths in the floorplan, perform a timing analysis and display results on the Timing Analyzer.

5.3. Optimize Critical Chains

Critical chains are design paths that limit further register retiming optimization. You can use the Hyper-Aware design flow to shorten design cycles and optimize critical chain performance for Stratix 10 and Agilex 7 devices. The Hyper-Aware design flow maximizes use of Hyper-Registers by combining automated register retiming with implementation of targeted timing closure recommendations (Fast Forward compilation). This sum of techniques drive the highest performance for Hyperflex® architecture designs.

A critical chain reports the design paths that limit further register retiming optimization. The Quartus Prime Pro Edition software provides the Hyper-Retimer critical chain reports to help you improve design performance. You can focus on higher level optimization, because the Hyper-Retimer uses Hyper-Registers to evenly balance slacks on all the registers in a critical chain.

Related Information

Hyperflex Architecture High-Performance Design Handbook

5.3.1. Viewing Critical Chains

Looking at the critical chain shows the exact logic that limits retiming operations in your design. For example, you can see if the retiming is limited by your RTL code, or by the constraints you applied on the design. Quartus Prime Pro Edition reports one critical chain per clock domain and clock domain crossing.

The critical chain is available at two different stages in the Hyper Aware Design Flow:

- In the Retiming Limit Details Report—this report for the retiming stage in the Hyper Aware Design Flow, and is enabled by default.
- In the Fast Forward Compilation Report—Click **Fast Forward Timing Closure Recommendations** on the Compilation Dashboard to run..
- You can also graphically visualize the critical chains in the Technology Map Viewer.

Related Information

- Stratix 10 HyperFlex Design: Analyzing Critical Chains (OS10CRCHNS) Online Course

5.4. Design Evaluation for Timing Closure

As you move towards completion of your design, you can begin evaluating your design for timing closure. Follow the techniques in this section to evaluate whether your design is likely to close timing. If your design requires further steps for timing closure, you can use the analysis techniques in this section to determine whether RTL changes can help you to close timing.

5.4.1. Review Messages

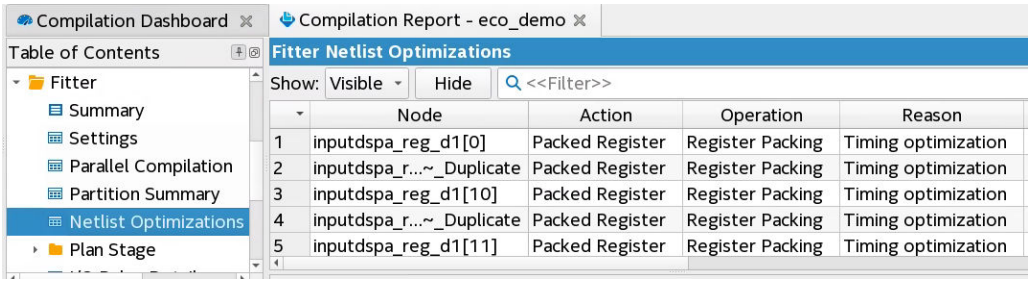
After compiling your design, review the messages in each section of the compilation report. Most designs that fail timing start out with other problems that the Fitter reports as warning messages during compilation. Determine what causes a warning message, and whether to fix or ignore the warning.

After reviewing the warning messages, review the informational messages. Take note of anything unexpected, for example, unconnected ports, ignored constraints, missing files, or other unexpected conditions.

5.4.2. Evaluate Fitter Netlist Optimizations

You can specify options that direct the Fitter to perform optimizations to the design netlist. Specify global options, such as register packing, duplicating or deleting logic cells, or inverting signals by clicking **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**.

Figure 27. Netlist Optimizations Report



5.4.3. Evaluate Optimization Results

After checking what optimizations were done and how they improved performance, evaluate the runtime it took to get the extra performance. To reduce compilation time, review the physical synthesis and netlist optimizations over a couple of compilations, and edit the RTL to reflect the changes that physical synthesis performed. If a particular set of registers consistently get retimed, edit the RTL to retime the registers the same way. If the changes are made to match what the physical synthesis algorithms did, the physical synthesis options can be turned off to save compile time while getting the same type of performance improvement.

5.4.4. Evaluate Resource Usage

Evaluate the device resources that the design consumes, including global and non-global signal usage, routing utilization, and clustering difficulty. Determine whether you approach capacity for any type of resource that might limit performance.

5.4.4.1. Evaluate Global and Non-Global Usage

For Arria 10 and Cyclone 10 GX designs that contain many clocks, evaluate global and non-global signals to determine whether global resources are used effectively, and if not, consider making changes. After running the Fitter, refer to the Global and Other Fast Signals report to review data on these signals.

Note: Stratix 10 and Cyclone 10 GX devices do not contain regional clocks, but use local routing.

The figure shows an example of inefficient use of a global clock.

Figure 28. Inefficient Use of a Global Clock in Arria 10 Design—Single Fan-Out from Global Clock

Global & Other Fast Signals

Location	Fan-Out	Global Resource Used	Global Line Name
FRACTIONALPLL_X98_Y2_N0	1	Global Clock	--
PLLOUTPUTCOUNTER_X98_Y2_N1	29044	Global Clock	GCLK7
PLLOUTPUTCOUNTER_X98_Y13_N1	253103	Global Clock	GCLK6
FF_X185_Y66_N13	280349	Global Clock	GCLK8
PIN_AE17	4887	Global Clock	GCLK4
FRACTIONALPLL_X98_Y11_N0	1	Global Clock	--
PLLOUTPUTCOUNTER_X98_Y3_N1	1	Global Clock	GCLK5
PLLOUTPUTCOUNTER_X98_Y1_N1	1691	Regional Clock	RCLK29
PLLOUTPUTCOUNTER_X98_Y8_N1	302	Regional Clock	RCLK23
PLLOUTPUTCOUNTER_X98_Y11_N1	141	Regional Clock	RCLK25
PLLOUTPUTCOUNTER_X98_Y10_N1	17	Regional Clock	RCLK22

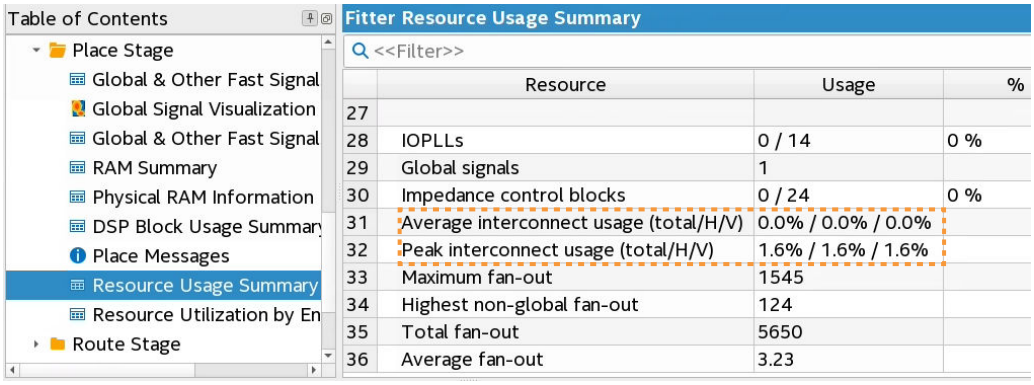
If you assign these resources to a Regional Clock, the Global Clock becomes available for another signal. You can ignore signals with an empty value in the **Global Line Name** column as the signal uses dedicated routing, and not a clock buffer. The Non-Global High Fan-Out Signals report lists the highest fan-out nodes not routed on global signals. `Reset` and `enable` signals appear at the top of the list.

If there is routing congestion in the design, and there are high fan-out non-global nodes in the congested area, consider using global or regional signals to fan-out the nodes, or duplicate the high fan-out registers so that each of the duplicates can have fewer fan-outs. Use the Chip Planner to locate high fan-out nodes, to report routing congestion, and to determine whether the alternatives are viable.

5.4.4.2. Evaluate Routing Usage

Review routing usage reported in the **Fitter Resource Usage Summary** report.

Figure 29. Fitter Resource Usage Summary Report



Average interconnect usage reports the average amount of interconnect that is used, out of what is available on the device. **Peak interconnect usage** reports the largest amount of interconnect used in the most congested areas.

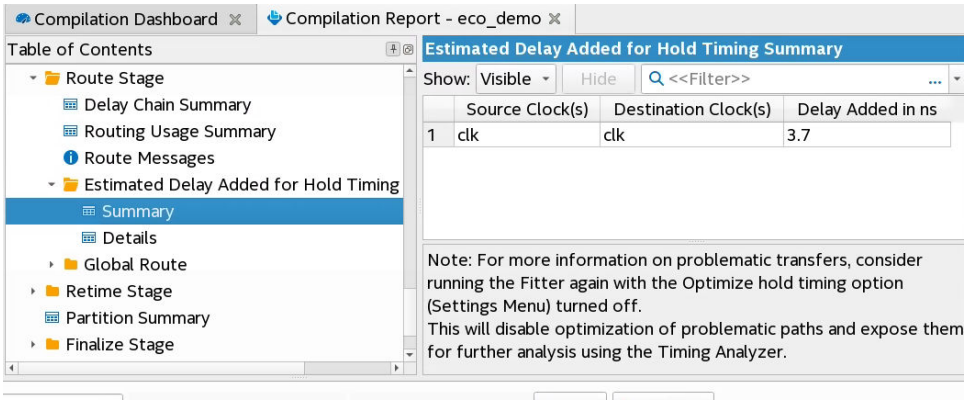
Designs with an average value below 50% typically do not have any problems with routing. Designs with an average between 50-65% may have difficulty routing. Designs with an average over 65% typically have difficulty meeting timing unless the RTL tolerates a highly utilized chip. Peak values at or above 90% are likely to have problems with timing closure; a 100% peak value indicates that all routing in an area of the device has been used, so there is a high possibility of degradation in timing performance.

5.4.4.3. Evaluate Wires Added for Hold

During routing the Fitter may add wire between register paths to increase delay to meet hold time requirements. The Fitter reports how much routing delay was added in the **Estimated Delay Added for Hold Timing** report. Excessive additional wire can indicate an error with the constraint. The cause of such errors is typically incorrect multicycle transfers between multi-rate clocks, and between different clock networks.

Review the specific register paths in the **Estimated Delay Added for Hold Timing** report to determine whether the Fitter adds excessive wire to meet hold timing.

Figure 30. Estimated Delay Added for Hold Timing Report

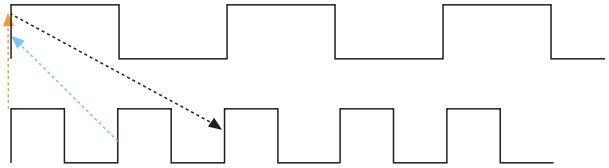


An example of an incorrect constraint which can cause the router to add wire for hold requirements is when there is data transfer from 1x to 2x clocks. Assume the design intent is to allow two cycles per transfer. Data can arrive any time in the two destination clock cycles by adding a multicycle setup constraint as shown in the example:

```
set_multicycle_path -from 1x -to 2x -setup -end 2
```

The timing requirement is relaxed by one 2x clock cycle, as shown in the black line in the waveform in the figure.

Figure 31. Timing Requirement Relaxed Waveform



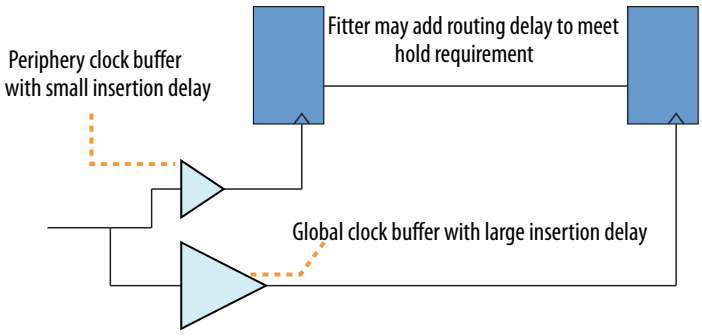
The default hold requirement, shown with the dashed blue line, can force the router to add wire to guarantee that data is delayed by one cycle. To correct the hold requirement, add a multicycle constraint with a hold option.

```
set_multicycle_path -from 1x -to 2x -setup -end 2
set_multicycle_path -from 1x -to 2x -hold -end 1
```

The orange dashed line in the figure above represents the hold relationship, and no extra wire is required to delay the data.

The router can also add wire for hold timing requirements when data transfers in the same clock domain, but between clock branches that use different buffering. Transferring between clock network types happens more often between the periphery and the core. The following figure shows data is coming into a device, a periphery clock drives the source register, and a global clock drives the destination register. A global clock buffer has larger insertion delay than a periphery clock buffer. The clock delay to the destination register is much larger than to the source register, hence extra delay is necessary on the data path to ensure that it meets its hold requirement.

Figure 32. Clock Delay



To identify cases where a path has different clock network types, review the path in the Timing Analyzer, and check nodes along the source and destination clock paths. Also, check the source and destination clock frequencies to see whether they are the

same, or multiples, and whether there are multicycle exceptions on the paths. Finally, ensure that all cross-domain paths that are false by intent have an associated false path exception.

If you suspect that routing is added to fix real hold problems, you can disable the **Optimize hold timing** advanced Fitter setting (**Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter) ➤ Optimize hold timing**). Recompile the design with **Optimize hold timing** disabled, and then rerun timing analysis to identify and correct any paths that fail hold time requirements.

Note: Disable the **Optimize hold timing** option only when debugging your design. Ensure to enable the option (default state) during normal compiles. Wire added for hold is a normal part of timing optimization during routing and is not always a problem.

5.4.5. Evaluate Other Reports and Adjust Settings Accordingly

5.4.5.1. Difficulty Packing Design

In the Fitter Resource Section, under the **Resource Usage Summary**, review the **Difficulty Packing Design** report. The **Difficulty Packing Design** report details the effort level (low, medium, or high) of the Fitter to fit the design into the device, partition, and Logic Lock region.

As the effort level of **Difficulty Packing Design** increases, timing closure gets harder. Going from medium to high can result in significant drop in performance or increase in compile time. Consider reducing logic to reduce packing difficulty.

5.4.5.2. Review Ignored Assignments

The Compilation Report includes details of any assignments that the Fitter ignores. The Fitter may ignore assignments if they refer to nodes names that change, but assignments are not updated accordingly. Make sure that the Fitter is not ignoring any valid assignments.

5.4.5.3. Review Non-Default Settings

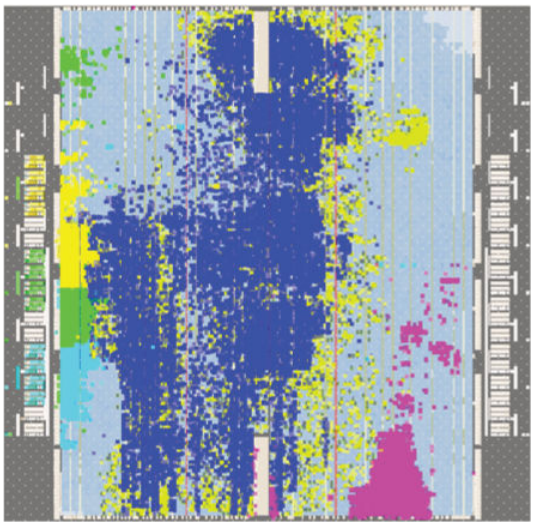
The Synthesis and Fitter reports list all settings set to a non-default value during the compilation. Review the non-default settings to ensure benefit.

5.4.5.4. Review the Design Floorplan

Use the Chip Planner for reviewing placement. You can use the Chip Planner to locate hierarchical entities, using colors for each located entity in the floorplan. Look for logic that seems out of place, based on where you expect it to be

For example, logic that interfaces with I/Os should be close to the I/Os, and logic that interfaces with an IP or memory should be close to the IP or memory.

Figure 33. Floorplan with Color-Coded Entities



The following notes describe use of the visualization in *Floorplan with Color-Coded Entities*:

- The green block is spread apart. Check to see if those paths are failing timing, and if so, what connects to that module that could affect placement.
- The blue and aqua blocks are spread out and mixed together. Check if connections between the two modules contribute to this.
- The pink logic at the bottom must interface with I/Os at the bottom edge. Check fan-in and fan-out of a highlighted module by using the buttons on the task bar. Look for signals that go a long way across the chip and see if they are contributing to timing failures.
- Check global signal usage for signals that affect logic placement, and verify if the Fitter placed logic feeding a global buffer close to the buffer and away from related logic. Use settings like high fan-out on non-global resource to pull logic together.
- Check for routing congestion. The Fitter spreads out logic in highly congested areas, making the design harder to route.

5.4.5.5. Adjust Placement Effort

You can increase the **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter) ➤ Placement Effort Multiplier** value to spend additional compilation time and effort in Place stage of the Fitter.

Adjust the multiplier after reviewing and optimizing other settings and RTL. Try an increased value, up to 4, and reset to default if performance or compile time does not improve.

5.4.5.6. Adjust Fitter Effort

Fitter **Optimization mode** settings allow you to specify whether the Compiler focuses optimization efforts for performance, resource utilization, power, or compile times.

By default, the Fitter **Optimization mode** is set to **Balanced (Normal flow)** mode, which reduces Fitter effort and compilation time as soon as timing requirements are met. You can optionally select another **Optimization mode** to target performance, area, routability, power, or compile time.

To increase Fitter effort further, you can also enable the **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter) ➤ Fitter Effort** option. The default **Auto Fit** setting reduces Fitter effort once timing requirements are met. **Standard Fit (highest effort)** setting uses maximum effort regardless of the design's requirements, leading to higher compilation time and more timing margin.

5.4.5.7. Review Timing Constraints

Ensure that you constrain all clocks with the correct frequency requirements.

To confirm the proper application of timing constraints, run the Design Assistant and then review and correct any timing constraint rule violations. In addition, you can review the **Ignored Constraints** report to locate any constraints assigned to invalid node names in the design. These invalid node names are most commonly caused by changes that you make in the design hierarchy that are not yet reflected in the constraint. Similarly, review the **Report Unconstrained Paths** report to locate unconstrained paths. Add constraints as necessary so that the Compiler can fully optimize the design.

5.4.6. Evaluate Clustering Difficulty

You can evaluate clustering difficulty to help reach timing closure. You can monitor clustering difficulty whenever you add logic and recompile. Use the clustering information to gauge how much timing closure difficulty is inherent in your design.

- If your design is full but clustering difficulty is low or medium, your design itself, rather than clustering, is likely the main cause of congestion.
- Conversely, congestion occurring after adding a small amount of logic to the design, can be due to clustering. If clustering difficulty is high, this contributes to congestion regardless of design size.

5.4.7. Revise and Recompile

Look for obvious problems that you can fix with minimal effort. To identify where the Compiler had trouble meeting timing, perform seed sweeping with about five compiles. Doing so shows consistently failing paths. Consider recoding or redesigning that part of the design.

To reach timing closure, a well written RTL can be more effective than changing your compilation settings. Seed sweeping can also be useful if the timing failure is very small, and the design has already been optimized for performance improvements and is close to final release. Additionally, seed sweeping can be used for evaluating changes to compilation settings. Compilation results vary due to the random nature of fitter algorithms. If a compilation setting change produces lower average performance, undo the change.

Sometimes, settings or constraints can cause more problems than they fix. When significant changes to the RTL or design architecture have been made, compile periodically with default settings and without Logic Lock regions, and re-evaluate paths that fail timing.

5.5. Timing Optimization

You can use the techniques and tools in this section to optimize timing when your design does not meet its timing requirements. Also, refer to the design recommendations in *Optimizing for Timing Closure, Quartus Prime Pro Edition User Guide: Design Recommendations*.

5.5.1. Correct Design Assistant Rule Violations

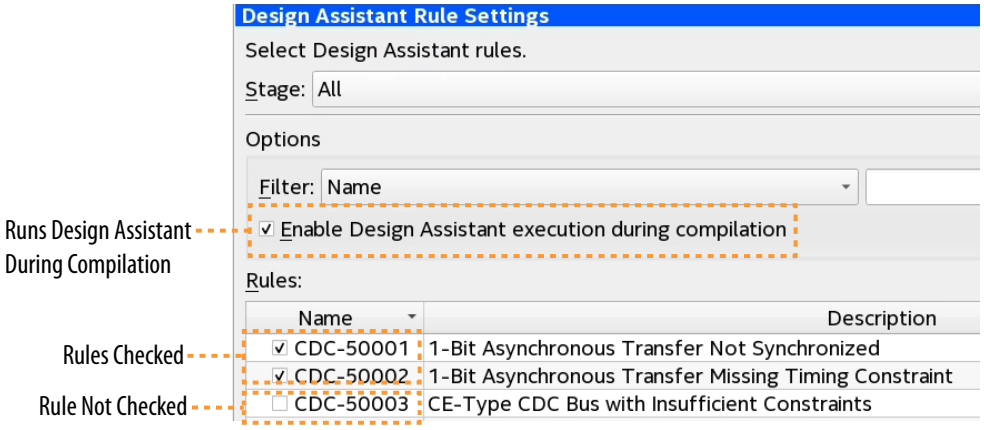
After running any stage of the Compiler, review the Design Assistant reports to analyze any design rule violations and view recommendations to correct failing paths. When enabled, the Quartus Prime Design Assistant automatically runs during compilation and reports any violations against a set of Intel FPGA-recommended design guidelines. Design Assistant rules include Timing Closure, Clocking, CDC, reset, and floorplanning.

You can customize the Design Assistant for your design characteristics and reporting requirements. Run Design Assistant in Compilation Flow mode to view the violations relevant for Compiler stages. Run in analysis mode from tools like the Timing Analyzer and Chip Planner to cross-probe from an individual rule violation to more information.

Follow these steps to enable and run Design Assistant and view results following compilation:

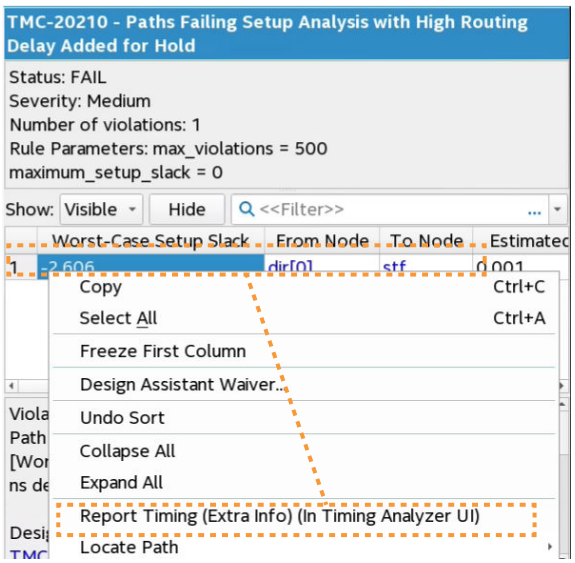
1. Click **Assignments ➤ Settings ➤ Design Assistant Rules Settings**.

Figure 34. Design Assistant Rules Settings



2. To enable Design Assistant checking during compilation, turn on **Enable Design Assistant execution during compilation**.
3. To run Design Assistant during compilation, run one or more modules of the Compiler. Design Assistant reports results for each stage in the Compilation Report.
4. To view the results for each rule, click the rule in the **Rules** list. A description of the rule and design recommendations for correction appear.
5. For timing path-related rule violations, right-click the node or path, and then click **Report Timing (Extra Info)** or **Report Path (Extra Info)**. The Timing Analyzer loads and automatically displays the **Report Timing** or **Report Path** data related to the rule violation, allowing you to probe every aspect of the violation. **Report Path** can report timing even for paths that are cut.

Figure 35. Cross Probing From Design Assistant Rule Violations to Timing Analyzer



Related Information

Quartus Prime Pro Edition User Guide: Design Recommendations

5.5.2. Implement Fast Forward Timing Closure Recommendations

In traditional FPGA timing closure flows, the starting point for most design analysis is the critical path. Due to the nature of Hyperflex architecture and the availability of the Hyper Retimer, it is best to start you timing closure activities from the Retiming Limit Report. Provide the Hyper-Retimer as many optimization opportunities as possible, before having to look into more time intensive and potentially manual timing closure techniques.

Related Information

Hyperflex Architecture High-Performance Design Handbook

5.5.2.1. Retiming Limit Details Report

Use the Retiming Limit Details report to get specific information on what is currently limiting the Hyper Retimer from performing more optimizations.

The Retiming Limit Details report specifies:

- Clock Transfer: Clock domain, or the clock domain transfer for which the critical chain applies
- Limiting Reason: Design conditions which prevent further optimizations from happening.
- Critical Chain Details: Timing paths associated with the timing restrictions.

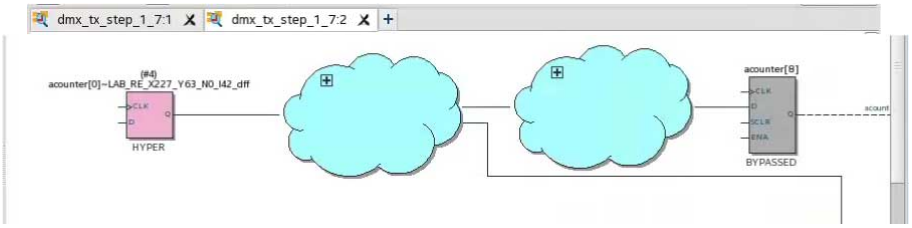
5.5.2.1.1. Using the Retiming Limit Details Report

To access the Retiming Limit Details report:

1. In the **Reports** tab, double-click **Retiming Limit Details** under **Fitter ➤ Retime Stage**.
2. To locate the critical chain in the Technology Map Viewer, right-click any path and click **Locate Critical Chain in Technology Map Viewer**.

   The Technology Map Viewer displays a schematic representation of the complete critical chain after place, route and register retiming.

Figure 36. Critical Chain in Technology Map Viewer



5.5.2.2. Fast Forward Timing Closure Recommendations

When running Fast Forward compilation, the Compiler removes signals from registers to allow mobility within the netlist for subsequent retiming. Fast Forward compilation generates design-specific timing closure recommendations, and predicts maximum performance with removal of all timing restrictions.

After you complete Fast Forward explorations, you can determine which recommendations to implement to provide the most benefit. Implement appropriate recommendations in your RTL, and recompile the design to achieve the performance levels that Fast Forward reports.

The Fast Forward Details Report provides the following information:

Table 14. Fast Forward Details Report Information

Name	Description
Step	Displays the various Fast Forward optimization steps, starting from the pre-optimization base compilation. • Each step comes with its associated critical chain. • Each step corresponds to a new optimization cumulative to the previous step.
Fast Forward Optimization	Analyzed Summary of the optimizations necessary to implement each step.
Estimated f_{MAX}	Estimated f_{MAX} performance after you implement the recommendations for this step in your design. This is cumulative, and step *n* represents the potential f_{MAX} after implementing all previous steps.
Optimization Analyzed	(cumulative) List of all the consecutive optimization steps applied.
Recommendation for Critical Chain	Lists recommended changes to your designs. These recommendations are geared towards removing retiming limitations, and allowing register movement.

5.5.2.2.1. Generating Fast Forward Timing Closure Recommendations

To generate Fast Forward timing closure recommendations:

1. On the Compilation Dashboard, click **Fast Forward Timing Closure Recommendations**.
   The Compiler runs prerequisite synthesis or Fitter stages as needed, and generates timing closure recommendations in the Compilation Report.
2. View timing closure recommendations in the Compilation Report to evaluate design performance, and implement key RTL performance improvements.

The Quartus Prime Pro Edition software allows you to automate or refine Fast Forward analysis:

- To run Fast Forward compilation during each full compilation, click **Assignments ➤ Settings ➤ Compiler Settings ➤ HyperFlex**, and turn on **Run Fast Forward Timing Closure Recommendations during compilation**.
- To modify how Fast Forward compilation interprets specific I/O and block types, click **Assignments ➤ Settings ➤ Compiler Settings ➤ HyperFlex Advanced Settings**.

5.5.2.2.2. Implementing Fast Forward Recommendations

After implementing timing closure recommendations in your design, you can rerun the Retime stage to obtain the predictive performance gains.

You can continue exploring performance and implementing RTL changes to your code until you reach the desired performance target. Once you have completed all the modifications you want to do, continue your timing closure activities with the traditional techniques explained in this document.

For more information about implementing Fast Forward timing closure recommendations in your design, refer to the *Implement Fast Forward Recommendations* section of the *Hyperflex Architecture High Performance Design Handbook*

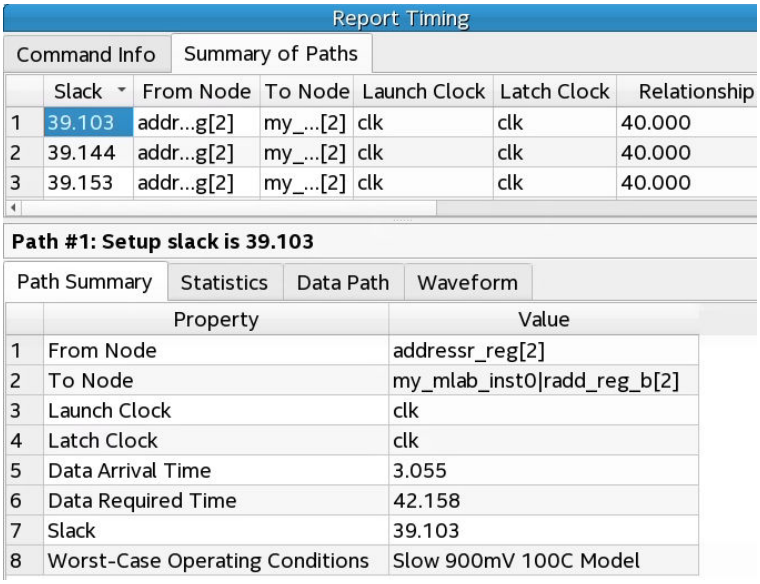
5.5.3. Review Timing Path Details

Reporting the timing paths and routing details can help uncover correctable timing and routing delays and other conditions that prevent retiming registers for higher performance.

5.5.3.1. Report Timing

The Timing Analyzer's **Reports ➤ Timing Slack ➤ Report Timing...** command allows you to specify settings to report the timing of any path or clock domain in the design. The equivalent scripting command is `report_timing`.

Figure 37. Report Timing Report



You can specify diverse options to customize the reporting. You can specify the **Clocks** and **Targets** that the report displays, the **Analysis Type** to run, whether to display **Extra Info** in the report, and the **Output** options for the report. For example, you can increase the number of paths to report, add a **Target** filter, and add a **From Clock**.

Figure 38. Report Timing Dialog Box (Top Section)

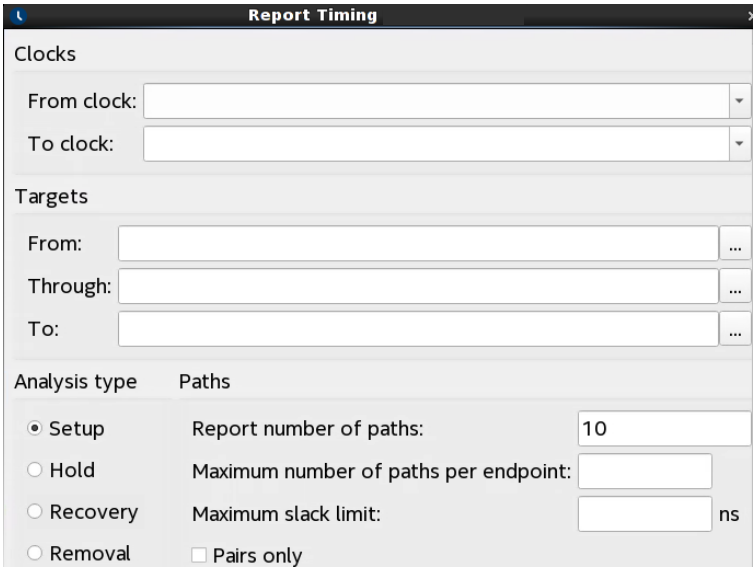


Figure 39. Report Timing Dialog Box (Bottom Section)

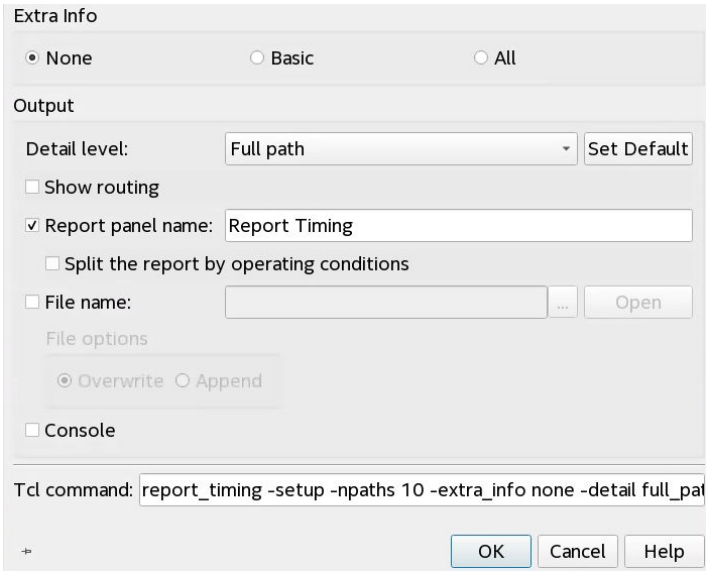

Table 15. Report Timing Settings

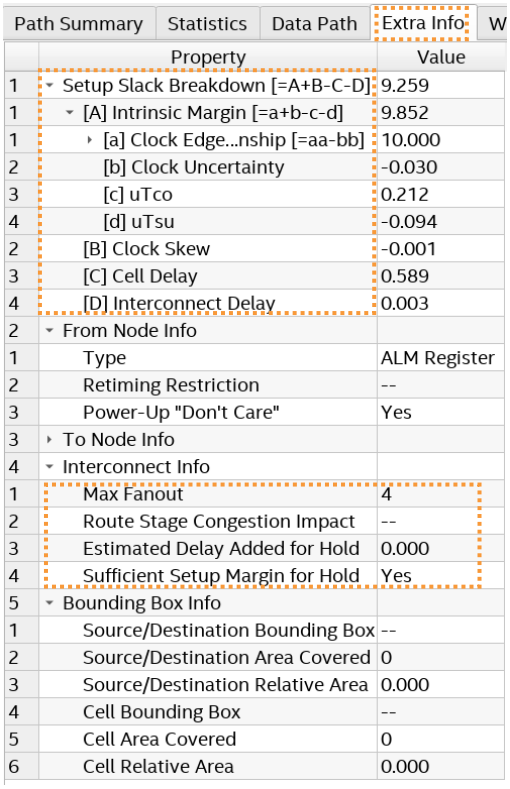
Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Targets	Specifies the target node for **From Clock** and **To Clock** to report paths with only those endpoints. Specify an I/O or register name or I/O port for this option. The field also supports wildcard characters. For example, to report only paths within a specific hierarchy: `report_timing -from *|egress:egress_inst|* \` `  -to *|egress:egress_inst|* -(other options)` When the **From**, **To**, or **Through** boxes are empty, the Timing Analyzer assumes all possible targets in the device. The **Through** option limits the report to paths that pass through combinatorial logic, or a particular pin on a cell.
Analysis type	The **Analysis type** options are **Setup**, **Hold**, **Recovery**, or **Removal**. The Timing Analyzer reports the results for the type of analysis you select.
Paths	Specifies the number of paths to display by endpoint and slack level. The default value for **Report number of paths** is 10, otherwise, the report can be very long. Enable **Pairs only** to list only one path for each pair of source and destination. Limit further with **Maximum number of paths per endpoints**. You can also filter paths by entering a value in the **Maximum slack limit** field.
Extra Info	Provides additional data that is relevant for diagnosing timing failure root cause, such as setup slack breakdown, and unexpected routing detours caused by congestion and hold time fix-up. Specify whether to include **None**, **Basic**, or **All** extra information in the report. The **Extra Info** tab data can help you identify potential, unnecessary routing detours, as well as placement or circuit issues that restrict the path f_{MAX} performance. Refer to Setup Slack Breakdown On the Extra Info Tab on page 81. • **All**—report includes **Extra Info** tab that reports extra information for source timing endpoints that pass through the unregistered output of a RAM or DSP block, or for destination timing endpoints that pass through the unregistered input of a DSP block. The **Data Path** tab includes Estimated Delay Added for Hold and Route Stage Congestion Impact data. • **Basic**—report includes the **Extra Info** tab but no extra information on the **Data Path** tab. • **None**—report includes no **Extra Info** tab or other extra information on the **Data Path** tab.
Output	Specify the path types the analysis includes in output for **Detail level**:

continued...

Option	Description
	• **Summary**—level includes basic summary reports. Review the **Clock Skew** column in the **Summary** report. If the skew is less than +/-150ps, the clock tree is well balanced between source and destination. • **Path only**—displays all the detailed information, except the **Data Path** tab displays the clock tree as one line item. • **Path and Clock**—displays the same as **Path only** with respect to the clock. • **Full path**—when higher clock skew is present, enable the **Full path** option. This option breaks the clock tree into greater detail, showing every cell, including the input buffer, PLL, global buffer (called CLKCTRL_), and any logic. Review this data to determine the cause of clock skew in your design. Use the **Full path** option for I/O analysis because only the source clock or destination clock is inside the FPGA, and therefore the delay is a critical factor to meet timing.
Show routing	Shows routing data in the report.
Split the report by operating conditions	For the operating condition timing corners, subdivides the data by each operating condition.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

Figure 40. Extra Info Tab

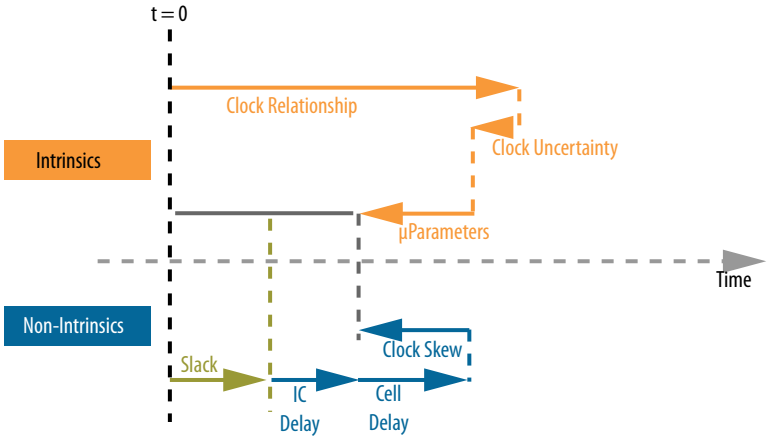


Setup Slack Breakdown On the Extra Info Tab

The **Extra Info** tab contains other timing metrics to help you diagnose timing closure issues, including **Setup Slack Breakdown** for the path.

The slack of a path specifies the margin by which the path meets its timing requirement. The setup slack breakdown is a numeric value that the Timing Analyzer calculates from the following timing requirements and path element delays:

Figure 41. Setup Slack Breakdown Calculations



A path can fail timing requirements for many varied reasons. For example, the clock relationship can be impossibly tight, or there can be excessive routing delays that alone cause failure for the timing path. Calculating the intrinsic margin of a timing path, and then comparing that margin to other delays of the path, can help identify the specific reasons why a path fails its timing requirement.

The **Extra Info** tab can help you identify potential significant or unexpected routing detours caused by congestion and hold time fix-up. The **Extra Info** tab can also report extra information for source timing endpoints that pass through the unregistered output of a RAM or DSP block, or for destination timing endpoints that pass through the unregistered input of a DSP block.

You can review the **Extra Info** data and **Locate Path** or **Locate Chip Area** in Chip Planner, Technology Map Viewer, or Resource Property Viewer to determine whether to make changes to improve placement and routing.

Some delay elements are more sensitive to a path's placement and routing than others. Intrinsic delays that are part of **Setup Slack Breakdown** are less sensitive to placement and routing, and are inherent in the RTL and timing requirements. Non-intrinsic delays are the other delays that are sensitive to placement and routing.

Table 16. Extra Info Tab Data

Extra Info Data	Description
Intrinsic Margin	Reports the intrinsic and non-intrinsic timing elements that comprise the timing path slack value. Intrinsic margin is a numeric value that the Timing Analyzer calculates from the timing requirements and path element delays. The Timing Analyzer also derives the slack of the path from the same requirements and delays, but with a different calculation. Intrinsic delays are less sensitive to placement and routing, and are inherent in the RTL and timing requirements. Non-intrinsic delays are the other delays that are sensitive to placement and routing.
From Node Info	Specifies the node Type, any Retiming Restriction, and any Power-Up "Don't Care" attributes for the From Node. Consider removing the retiming restriction to allow retiming and improve performance for timing closure.
To Node Info	Specifies the node Type, any Retiming Restriction, and any Power-Up "Don't Care" attributes for the To Node. Consider removing the retiming restriction to allow retiming and improve performance for timing closure.
Max Fanout	Reports the maximum fan-out of register and combinational nodes in the path.
Route Stage Congestion Impact	Reports whether routing has a **Low**, **Medium**, or **High** impact on congestion. A **Low** value suggests timing issues are not congestion related. A **High** value suggests competition for scarce routing resources plays a role in poor timing.
Estimated Delay Added for Hold	Reports the estimated amount of delay added on to the fastest delay route to satisfy hold. This value can help you determine whether delays are routing congestion or Hold related.
Sufficient Setup Margin for Hold	Reports whether the setup margin is suitable for the hold timing. **Yes**, indicates that the setup margin is sufficient. **No** indicates that the setup margin is insufficient for hold timing.
Source/Destination Bounding Box	Reports the lower-left and upper-right coordinates for the boundary box enclosing the source and destination registers. In an ideal case, the **Source/Destination Bounding Box**, **Cell Bounding Box**, and **Interconnect Bounding Box** values are roughly the same, and the relative areas are approximately 1.0. If the cell bounding box size grows relative to the **Source/Destination Bounding Box**, that can indicate a potential unnecessary routing detour on the path.
Source/Destination Area Covered	Reports the total area covered in terms of LABs.
Source/Destination Relative Area	Reports the area for the source and destination, relative to the **Source/Destination Bounding Box**. The value is always 1.0, which equals the same size.
Cell Bounding Box	Reports the lower-left and upper-right coordinates for the boundary box enclosing the source and destination registers, and any cells in the path.
Cell Area Covered	Reports the area for the cell, relative to the **Source/Destination Bounding Box**. A value of 1.0 equals the same size. A value greater than 1.0 can indicate a path has a cell outside of the space between the registers in the path.

The following describe the interpretation of timing conditions indicated by the **Setup Slack Breakdown**:

- **When the Setup Slack Breakdown is less than 0**—the path has such a tight timing relationship, a significant difference in microparameters, or such significant clock source uncertainty, that the path fails before the addition of any delay. Review the SDC constraints to verify that the timing relationship is correct. An incorrect relationship can exist between unrelated clocks that lack the proper timing cut. Ensure that parameterizable hard blocks (such as 20K RAM and DSP blocks) are fully registered. Investigate clock sources to verify that the clocks use global signals for routing.
- **When the clock skew exceeds the Setup Slack Breakdown**—address the clock transfer to meet timing on the path. You may need to create clock region assignments. You might also need to redesign cross-clock transfers to switch from synchronous to asynchronous implementation, such as with a FIFO or other handshake.

- **When the cell delay is greater than its intrinsic margin**—reduce the cell delay, as the path would fail timing even if the clocks are perfect and use no routing wires. Rewrite RTL to reduce the logic depth, restructure logic to allow the Compiler to use faster LUT inputs, or unblock retiming optimizations. The Compiler can automatically retime registers to reduce logic depth, but only in ways that maintain functionality and that the device architecture supports. To unblock the Hyper-Retimer, remove asynchronous resets and initial conditions.
- **When the interconnect delay is greater than its intrinsic margin**—the path would fail timing even if the clocks are perfect, and there is no logic. This occurs if registers are too far apart, or a timing path detours around a congested chip area. Review the fan-in and fan-out of registers that are far apart. Apply Logic Lock regions so the Fitter places the registers closer together. Use Logic Lock regions only after determining why placement is initially poor.

5.5.3.2. Report Logic Depth

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Logic Depth...** command allows you to report the number of logic levels within a clock domain. This value typically corresponds to the number of look-up tables (LUTs) that a path passes through.

The equivalent scripting command is `report_design_metrics -logic_depth`. **Report Logic Depth** shows the distribution of logic depth among the critical paths, allowing you to identify areas where you can reduce logic levels in your RTL.

Figure 42. Report Logic Depth (Histogram)

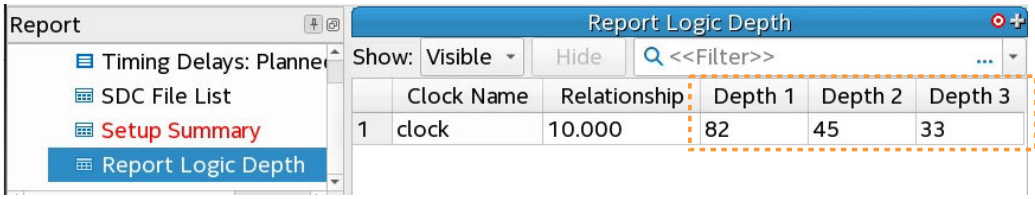

Figure 43. Report Paths of Depth 3

Call report logic depth by topology for each clock, intraclock only.

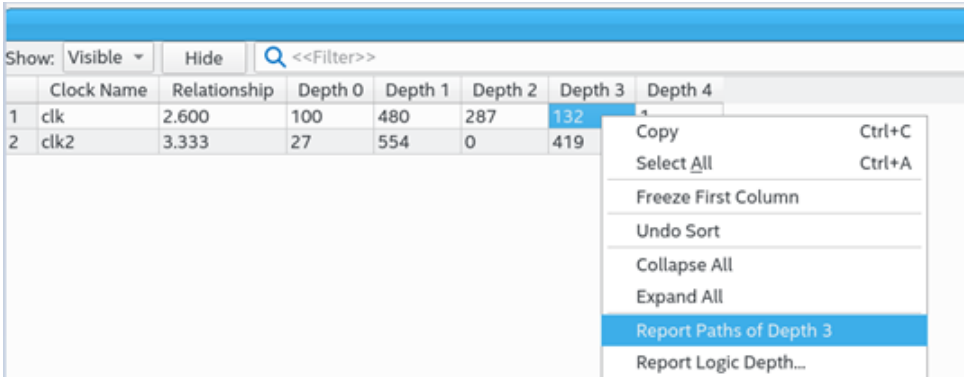

Figure 44. Summary of Paths

Close timing with accurate histogram cross probing.

You can specify various options to customize the reporting.

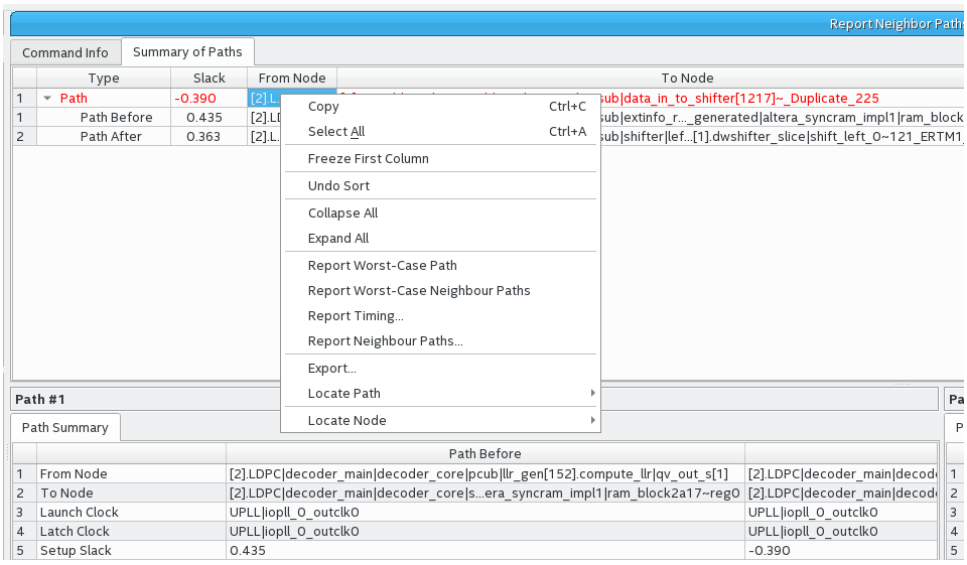
Table 17. Report Logic Depth Settings

Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Targets	Specifies the target node for **From Clock** and **To Clock** to report logic depth with only those endpoints. Specify an I/O or register name or I/O port for this option. The field also supports wildcard characters. When the **From**, **To**, or **Through** boxes are empty, the Timing Analyzer assumes all possible targets in the device. The **Through** option limits the report for paths that pass through combinatorial logic, or a particular pin on a cell.
Analysis type	The **Setup**, **Hold**, **Recovery**, and **Removal** analyses report the logic depths of the top *X* paths by slack. **Topology** analysis reports the logic depths of the top *X* paths by logic depth.
Paths	Specifies the number of paths to display by endpoint and slack level. The default value for **Report number of paths** is 10, otherwise, the report can be very long. Enable **Pairs only** to list only one path for each pair of source and destination. Limit further with **Maximum number of paths per endpoints**. You can also filter paths by entering a value in the **Maximum slack limit** field.
Detail	Specify whether to display on **Histogram** or full **Path** level of detail.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

5.5.3.3. Report Neighbor Paths

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Neighbor Paths...** command helps you to determine the root cause of critical paths (for example, high logic level, retiming limitation, sub-optimal placement, I/O column crossing, hold fix-up, time borrowing, or others). The equivalent scripting command is `report_design_metrics -neighbor_paths`.

Figure 45. Report Neighbor Paths Report



Report Neighbor Paths reports the most timing-critical paths in the design, including associated slack, additional path summary information, and path bounding boxes. **Report Neighbor Paths** shows the most timing-critical **Path Before** and **Path After** each critical **Path**. You can optionally view multiple before and after paths. Retiming or logic balancing of the **Path** can simplify timing closure if there is negative slack on the **Path**, but positive slack on the **Path Before** or **Path After**.

Table 18. Report Neighbor Path Dialog Box Settings

Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Targets	Specifies the target node for **From Clock** and **To Clock** to report neighbor paths with only those endpoints. Specify an I/O or register name or I/O port for this option. The field also supports wildcard characters. When the **From**, **To**, or **Through** boxes are empty, the Timing Analyzer assumes all possible targets in the device. The **Through** option limits the report for paths that pass through combinatorial logic, or a particular pin on a cell.
Analysis type	The **Analysis type** options are **Setup**, **Hold**, **Recovery**, or **Removal**. The Timing Analyzer reports the results for the type of analysis you select.
Paths	Specifies the number of paths to display by endpoint and slack level. The default value for **Report number of paths** is 10, otherwise, the report can be very long. Enable **Pairs only** to list only one path for each pair of source and destination. Limit further with **Maximum number of paths per endpoints**. You can also filter paths by entering a value in the **Maximum slack limit** field.
Report Number of Neighbor Paths	Specifies the number of neighbor paths to report, allowing you to view a number of the top adjacent paths entering the critical path, and the top paths exiting the critical path.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.
Extra Info	Specifies extra info.

5.5.3.4. Report Register Spread

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Register Spread...** command analyzes the final placement to identify registers with sinks pulling them in various directions. These registers are potential candidates for duplication. The equivalent scripting command is `report_register_spread`.

Registers that drive in opposite directions and connect to high fan-out can have placement-warping effects on the floorplan that impact f_{MAX}. The placement-warping may not cause timing failures. Therefore, you can view this report to identify such registers. Taking steps to address the registers listed in the report can make placement of the design easier and improve f_{MAX} performance.

You can automate duplication of registers with the `DUPLICATE_REGISTER` and `DUPLICATE_HIERARCHY_DEPTH` `.qsf` assignments, or you can manually modify RTL to duplicate registers or refactor logic. Refer to "Automatic Register Duplication: Hierarchical Proximity" in *Quartus Prime Pro Edition User Guide: Design Optimization*.

Figure 46. Report Register Spread Report

Report Register Spread

Show: Visible | Hide | <<Filter>>

Register Name	Register_Location	Number of Endpoints	Endpoint Centroid	Total Distance of Endpoints
counter_a[0]~ERTM	(69, 67)	78	(69, 67)	117.0
counter_a[1]~ERTM	(68, 67)	39	(68, 66)	21.4
counter_b[1]~ERTM	(70, 67)	39	(70, 67)	21.4
counter_b[2]~ERTM	(70, 67)	38	(70, 67)	20.9
counter_a[2]~ERTM	(68, 67)	38	(68, 66)	20.9
counter_b[3]~ERTM	(70, 67)	37	(70, 66)	20.4

You can specify various options to customize the report.

Table 19. Report Register Spread Settings

Option	Available Settings
Spread Type	Specifies the type of spread data in the report: • **Tension**—reports the sum over each sink of the distance from it to the centroid of all the sinks. • **Angle**—reports how far around the source register the fan-outs wrap, expressed from 0 to 360 degrees. This value corresponds to 360 minus the maximum angle between any two angularly adjacent sinks. This metric complements **Tension** by identifying registers which are surrounded by their sinks in all directions, and not those registers only being pulled in a few directions. • **Span**—reports the maximum 1-dimensional delta between the left bottom-most sink and the right top-most sink. • **Area**—reports the coverage of the sinks by number of LABs on the FPGA device. This option multiplies the span of the sinks in both X- and Y- dimensions. This metric complements **Span** by incorporating both dimensional spans of the sinks, and not only the maximum sink. • **Count**—reports registers with the largest sink counts.
Sink Type	Specifies the type of sink in the report: • **Endpoint**—the nodes (usually registers) that terminate timing paths from a register. • **Immediate Fanout**—the immediately connected nodes of the register. For example, lookup tables, other registers, RAM, or DSP blocks.
From Clock	Filters paths in the report to show only the launching clocks you specify.

continued...

Option	Available Settings
To Clock	Filters paths in the report to show only the latching clocks you specify, allowing you to debug one clock at a time.
Report number of registers	Specifies the number of registers to display in the report. The default value for **Report number of registers** is 10.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

Figure 47. Report Register Spread Types

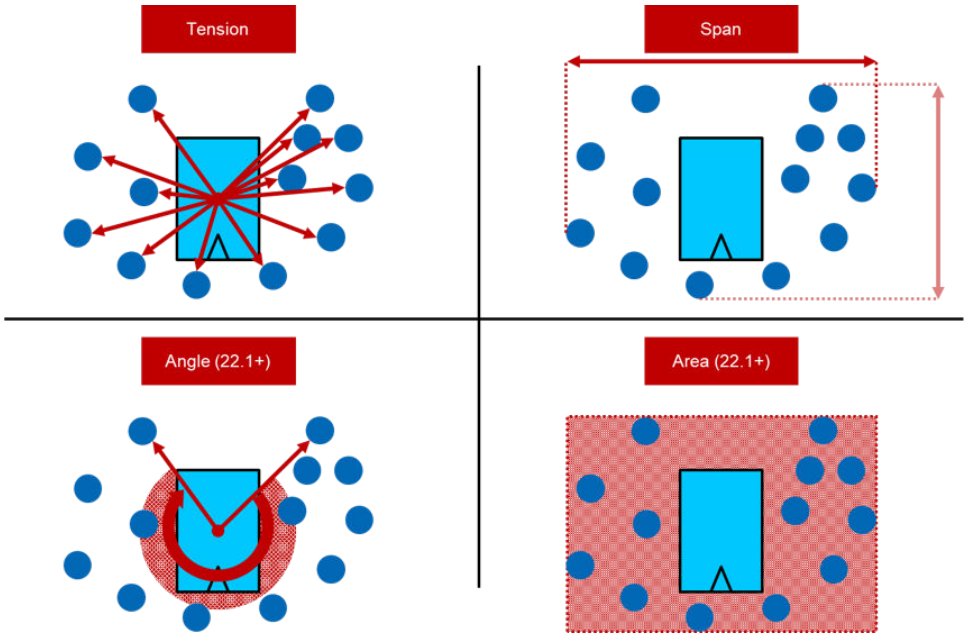


Figure 48. Report Register Spread Dialog Box

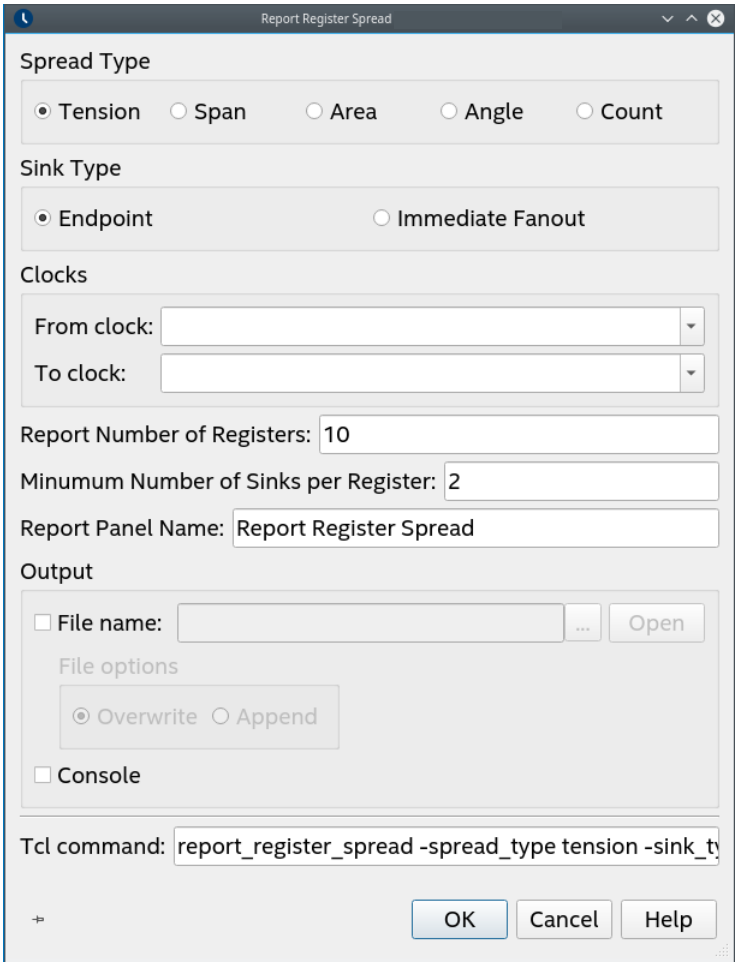

5.5.3.5. Report Route Net of Interest

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Route Net of Interest...** command allows you to report the nets that require the most effort from the router. The report shows the percentage of total router effort for the nets reported. The equivalent scripting command is `report_route_net_of_interest`.

This report allows you to identify nets that should not require significant router effort. For example, you might expect that low speed management interface nets are not timing critical, and therefore not require much router effort. However, if **Report Route Net of Interest** reports that some nets in the low speed management interface require significant effort from the router, you can investigate that further. The investigation can determine whether the timing constraints are correct, whether the fan-out is significant and can reduce through driver duplication, or whether the net passes through congested areas.

Figure 49. Report Route Net of Interest Report

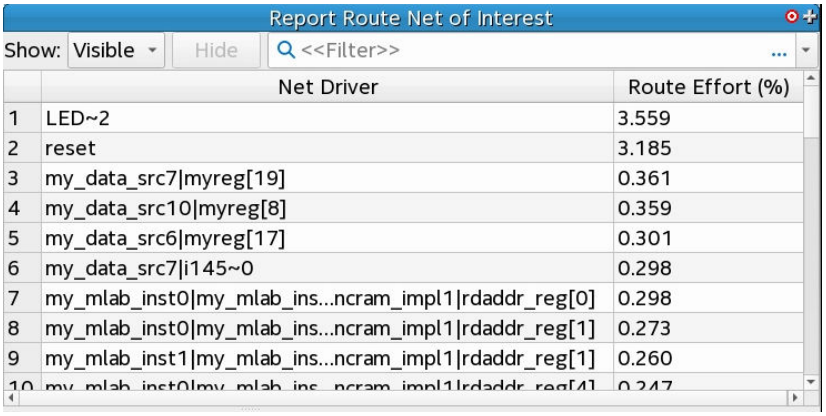

Figure 50. Report Route Net of Interest Dialog Box

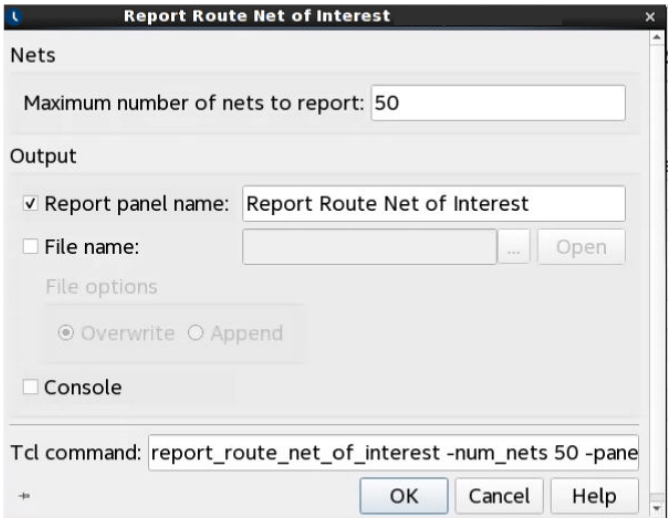


From the Route Net of Interest Report in the Timing Analyzer GUI, you can right-click on any net and run Report Timing for more details about the net, its slack, and any of the net's paths.

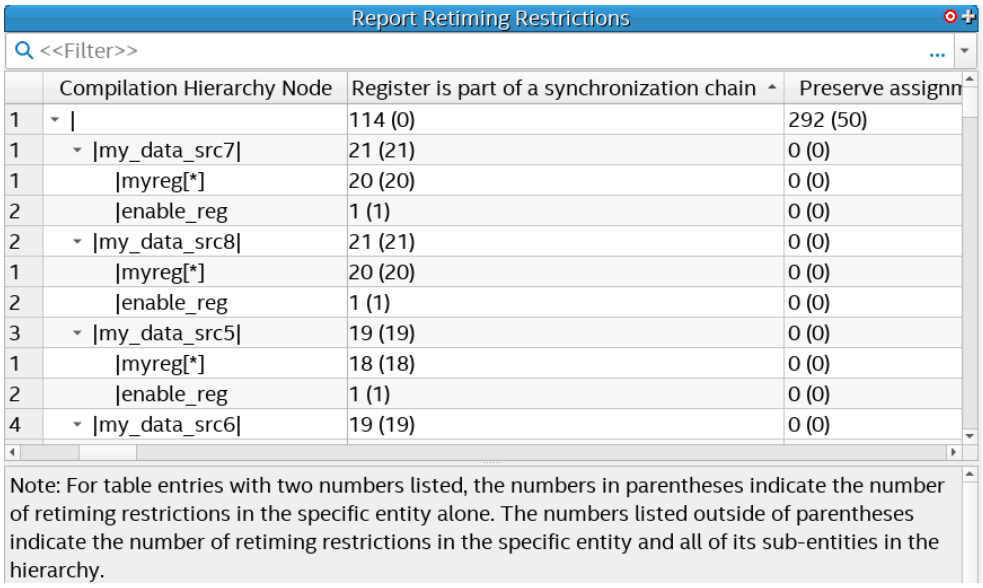
Table 20. Report Route Net of Interest Settings

Option	Available Settings
Nets	Specifies the **Maximum number of nets to report**. The default value is 50.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

5.5.3.6. Report Retiming Restrictions

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Retiming Restrictions...** command allows you to report the occurrences of design conditions that restrict Hyper-Retiming, such as Power-up "Care" restrictions, and don't touch or preserve attributes for each port. You can refer to this report to improve the circuit and remove retiming restrictions that limit circuit performance. `report_retiming_restrictions` is the equivalent scripting command.

Figure 51. Report Retiming Restrictions Report



For table entries with two number values, the number in parentheses indicates the number of retiming restrictions in the specific entity alone. The number listed outside of parentheses indicates the number of retiming restrictions in the specific entity and all of its sub-entities in the `hierarchy`.

Retiming Restrictions and Workarounds, Hyperflex Architecture High-Performance Design Handbook

5.5.3.7. Report Pipelining Information

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Pipelining Information...** command allows you to generate a report that can help you to identify potential areas of over-pipelining in your design. Excessive pipelining unnecessarily consumes area. The equivalent scripting command is `report_pipelining_info`.

Report Pipelining Information... does not perform any functional analysis in making the recommended pipeline stage adjustment. You must be aware of any potential functional changes from removing pipeline stages. There may be circumstances when all the stages in a register pipeline are necessary for functional reasons. The report helps to identify location with more registers than necessary for covering distance.

18	u_final_dat_hp|GEN_REG_INPUT.R_data[17][0]	2.809	0	1
19	u_final_dat_hp|GEN_REG_INPUT.R_data[18][0]	2.865	0	1
20	u_final_dat_hp|GEN_REG_INPUT.R_data[19][0]	2.743	2	1
21	final_dat[0]~reg0	2.855	0	1

To help identify potential over-pipelining, **Report Pipelining Information** reports:

- The recommended pipeline stage adjustment across bus
- The minimum total slack of one bit across bus
- The minimum average slack of one bit across bus
- The distance between the registers
- The width of buses in your design
- The number of sequential registers
- The number of registers on the bus

The Recommended Pipeline Stage Adjustment Across Bus reports the number of registers that you can remove from the bus for each bit. The Average Distance Per Stage, Max Distance Per Stage, and Min Distance Per Stage columns report the Manhattan distance measured in logic array blocks (LABs). The Bus Average Depth, Bus Max Depth, and Bus Min Depth columns report the number of sequential, single fan-out registers. For registers that have more than one clock source, the report lists the fastest one.

The **1+** sign under Recommended Pipeline Stage Adjustment Across Bus column means that the bus might need to add more registers to meet timing requirement. Refer to the Fast Forward Timing Closure Recommendations report.

If the report identifies a large register chain with multiple sequential registers, and the distance between registers is low, that condition can suggest over-pipelining. You may be able to remove some registers to recover some of the device area and reduce congestion.

The following options are available for this report:

Figure 55. Report Pipelining Information Dialog Box

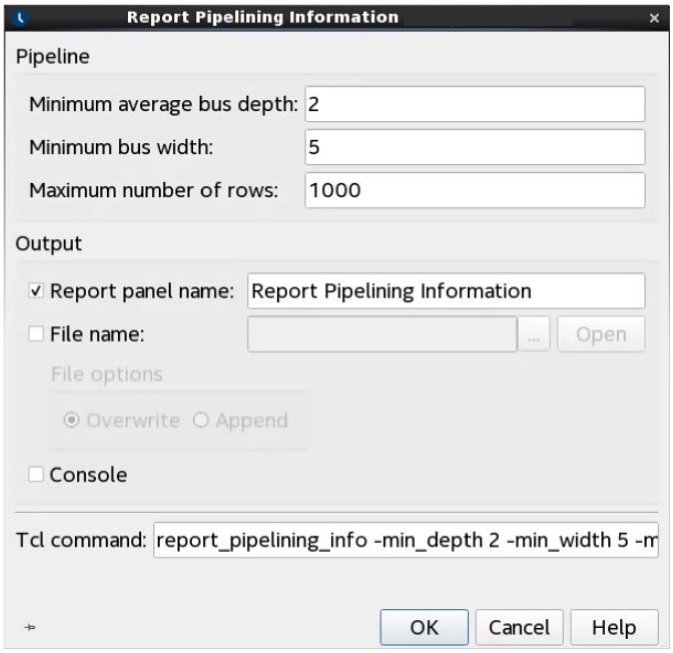

Table 21. Report Pipelining Information Settings

Option	Available Settings
Pipeline	Specifies the thresholds for reporting a register pipeline. You can define the **Minimum average bus depth**, the **Minimum bus width**, and the **Maximum number of rows** that the report includes.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

5.5.3.8. Report CDC Viewer

The Timing Analyzer's **Reports ➤ Clock Domain Crossings ➤ Report CDC Viewer...** command allows you to configure and display a custom clock domain crossing report and the Clock Domain Crossing (CDC) Viewer. The CDC Viewer graphically displays the setup, hold, recovery, or removal analysis of all clock transfers in your design. The equivalent scripting command is `report_cdc_viewer`.

Table 22. Report Clock Domain Crossing Viewer Settings

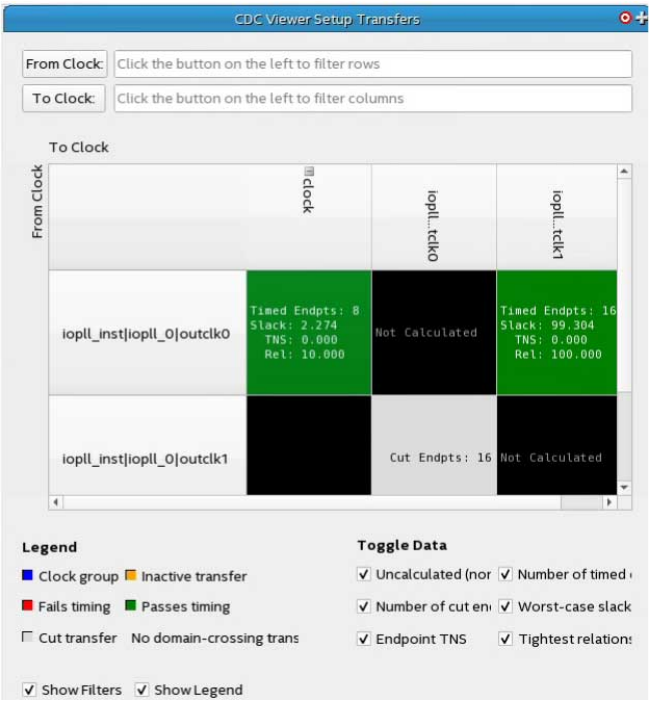
Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Analysis type	Options are **Setup**, **Hold**, **Recovery**, or **Removal**. The Timing Analyzer reports the results for the type of analysis you select.
Transfers	Specifies the type of clock transfers to include or exclude from the report, including **Timed transfers**, **Fully cut transfers**, **Clock groups, Inactive clocks**, and **Non-crossing transfers**. You can specify the **Maximum slack limit** and **Grid options** for the report.
Detail level	**Full** shows all details of the report and **Summary** filters the details and shows summary data.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data, and specify **Grid** or **List** format. *Note:* In grid format reports, clocks with non-crossing transfers always appear if they have transfers between other clocks.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

You can specify the following options to customize CDC Viewer reporting:

Table 23. CDC Viewer Report Controls

Control	Description
From Clock: and **To Clock:**	Filters the display according to the clock names you specify. Click **From Clock:** or **To Clock:** to search for specific clock names.
Legend	Defines the status colors. A color coded grid displays the clock transfer status. The clock headers list each clock with transfers in the design. The GUI truncates long clock names, but you can view the full name in a tool tip or by resizing the clock header cell. The GUI represents the generated clocks as children of the parent clock. A '+' icon next to a clock name indicates the presence of generated clocks. Clicking on the clock header displays the generated clocks associated with that clock.
Toggle Data	The text in each transfer cell contains data specific to each transfer. Turn on or off display of the following types of data: • **Number of timed endpoints** between clocks— the number of timed, endpoint-unique paths in the transfer. A path being "timed" means that analysis occurs on that path. Only paths with unique endpoints count towards this total. • **Number of cut endpoints** between clocks— the number of cut endpoint-unique paths, instead of timed paths. These paths are cut by either a false path or clock group assignment. Timing analysis skips such paths. • **Worst-case slack** between clocks— the worst-case slack among all endpoint-unique paths in the transfer. • **Total negative slack** between clocks— the sum of all negative slacks among all endpoint-unique paths in this transfer. • **Tightest relationship** between clocks— the lowest-value setup, hold, recovery, or removal relationship between the two clocks in this transfer.
Show Filters and **Show Legend**	Turns on or off Filters and **Legend**.

Figure 56. CDC Viewer Setup Transfers Report



Each block in the grid is a transfer cell. Each transfer cell uses color and text to display important details of the paths in the transfer. The color coding represents the following states:

Table 24. Transfer Cell Content

Cell Color	Color Legend
Black	Indicates no transfers. There are no paths crossing between the source and destination clock of this cell.
Green	Indicates passing timing. All timing paths in this transfer, that have not been cut, meet their timing requirements.
Red	Indicates failing timing. One or more of the timing paths in the transfer do not meet their timing requirements. If the transfer is between unrelated clocks, the paths likely require a synchronizer chain.
Blue	Indicates clock groups. The source and destination clocks of these transfers are cut by means of asynchronous clock groups.
Gray	Indicates a cut transfer. All paths in this transfer are cut by false paths. Therefore, timing analysis does not consider these paths.
Orange	Indicates inactive clocks. One of the clocks in the transfer is an inactive clock (with the `set_active_clocks` command). The Timing Analyzer ignores such transfers.

Right-click menus allow you to perform operations on transfer cells and clock headers. When the operation is a Timing Analyzer report or SDC command, a dialog box opens containing the contents of the transfer cell.

Table 25. Transfer Cell Right-Click Menus

Command	Description
Copy	Copies the contents of the transfer cell or clock header to the clipboard.
Report Timing	Reports timing. Not available for transfer cells with no valid paths (gray or black cells).
Report Endpoints	Reports endpoints. Not available for transfer cells with no cut paths (gray or black cells).
Report False Path	Reports false paths. Not available for transfer cells with no valid paths (black cells).
Report Exceptions	Reports exceptions. Only available for clock group transfers (blue cells).
Report Exceptions (with clock groups)	Reports exceptions with clock groups. Only available for clock group transfers (blue cells).
Set False Path	Sets a false path constraint.
Set Multicycle Path	Sets a multicycle path exception.
Set Min Delay	Sets a min delay constraint.
Set Max Delay	Sets a max delay constraint.
Set Clock Uncertainty	Sets a clock uncertainty constraint.

Table 26. Clock Header Right-Click Menus

Command	Description
Copy (include children)	Copies the name of the clock header, and the names of each of its derived clocks. This option only appears for clock headers with generated clocks.
Expand/Collapse All Rows/Columns	Shows or hides all derived clocks in the grid.
Create Slack Histogram	Generates a slack histogram report for the clock you select.
Report Timing From/To Clock	Generates a timing report for the clock you select. If you do not expand the clock to display derived clocks, the timing report includes all clocks that derive from the clock. To prevent this, expand the clock before right-clicking it.
Remove Clock(s)	Removes the clock you select from the design. If you do not expand the clock, timing analysis removes all clocks that derive from the clock.

You can view CDC Viewer output in any of the following formats:

- A report panel in the Timing Analyzer
- Output in the Timing Analyzer Tcl console
- A plain-text file
- An HTML file you can view in a web browser.

Related Information

Tips for Analyzing Failing Clock Paths that Cross Clock Domains on page 129

5.5.3.9. Timing Closure Recommendations

The **Report Timing Closure Recommendations** command in the Timing Analyzer **Task** pane analyzes paths and provides specific recommendations based on path characteristics. Since Design Assistant now provides more targeted timing closure recommendations, **Report Timing Closure Recommendations** is marked for deprecation.

5.5.3.10. Global Network Buffers

Routing paths allow you to identify global network buffers that fail timing. Buffer locations names reflect the network they drive.

- CLK_CTRL_Gn—for Global driver
- CLK_CTRL_Rn—for Regional driver

Buffers that access the global networks are in the center of each side of the device. Buffering to route a core logic signal on a global signal network causes insertion delay. Trade-offs to consider for global and non-global routing are source location, insertion delay, fan-out, distance a signal travels, and possible congestion if the signal demotes to local routing.

5.5.3.10.1. Source Location

If you cannot move the register feeding the global buffer closer, then consider changing either the design logic or the routing type.

5.5.3.10.2. Insertion Delay

If the design requires a global signal, consider adding half a cycle to timing by using a negative-edge triggered register to generate the signal, and use a multicycle setup constraint.

Figure 57. Negative-Edge Triggered Register

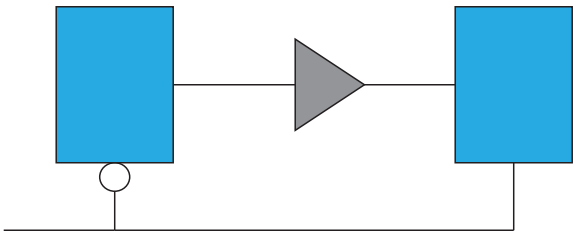


Figure 58. Multicycle Setup Constraint

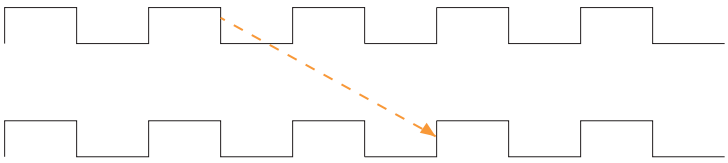


```
set_multicycle_path -from <generating_register> -setup -end 2
```

5.5.3.10.3. Fan-Out

Nodes with very high fan-out that use local routing tend to pull logic that they drive close to the source node. This can make other paths fail timing. Duplicating registers can help reduce the impact of high fan-out paths. Consider manually duplicating and preserving these registers. Using a MAX_FANOUT assignment may make arbitrary groups of fan-out nodes, whereas a designer can make more intelligent fan-out groups.

5.5.3.10.4. Global Signal Assignment

You can use the Global Signal assignment to control the global signal usage on a per-signal basis. For example, if a signal needs local routing, you set the Global Signal assignment to **Off**.

5.5.3.11. Resets and Global Networks

The Compiler often routes reset signals on global networks. Sometimes, the use of a global network causes recovery failures. Consider reviewing the placement of the register that generates the reset and the routing path of the signal.

5.5.3.12. Suspicious Setup

Suspicious setup failures include paths with very small or very large requirements.

One typical cause is math precision error. For example, 10Mhz/3 = 33.33 ns per period. In three cycles, the time is 99.999 ns vs 100.000 ns. Setting a maximum delay can provide an appropriate setup relationship.

Another cause of failure are paths that must be false by design intent, such as:

- Asynchronous paths handled through FIFOs, or
- Slow asynchronous paths that rely on handshaking for data that remain available for multiple clock cycles.

To prevent the Fitter from having to meet unnecessarily restrictive timing requirements, consider adding false or multicycle path statements.

5.5.3.13. Auto Shift Register Replacement

During synthesis, the Compiler can convert shift registers or register chains into RAMs to save area. However, conversion to RAM often reduces speed. The Compiler names the converted registers with the prefix "altshift_taps".

- If paths that fail timing begin or end in shift registers, consider disabling the **Auto Shift Register Replacement** option. Do not convert registers that are intended for pipelining.
- For shift registers that are converted to a chain, evaluate area/speed trade off of implementing in RAM or logic cells.
- If a design uses nearly the full device capacity, you can save area by shifting register conversion to RAM, benefiting non-critical clock domains. You can change the settings from the default **AUTO** to **OFF** globally, or on a register or hierarchy basis.

5.5.3.14. Clocking Architecture

For better timing results, place all registers driven by a regional clock in one quadrant of the chip. You can review the clock region boundaries in the Chip Planner.

Timing failure can occur when the I/O interface at the top of the device connects to logic driven by a regional clock which is in one quadrant of the device, and placement restrictions force long paths to and from I/Os to logic across quadrants.

Use a different type of clock source to drive the logic, such as global, which covers the whole device, or dual-regional which covers half the device. Alternatively, you can reduce the frequency of the I/O interface to accommodate the long path delays. You can also redesign the pinout of the device to place all the specified I/Os adjacent to the regional clock quadrant. This issue can happen when register locations are restricted, such as with Logic Lock regions, clocking resources, or hard blocks (memories, DSPs, IPs).

The **Extra Fitter Information** tab in the Timing Analyzer timing report informs you when placement is restricted for nodes in a path.

Related Information

Viewing Available Clock Networks in Chip Planner on page 149

5.5.4. Try Optional Fitter Settings

This section focuses only on the optional timing-optimization Fitter settings, which are the **Optimize Hold Timing**, **Optimize Multi-Corner Timing**, and **Fitter Aggressive Routability Optimization**.

Caution: The settings that best optimize different designs might vary. The group of settings that work best for one design does not necessarily produce the best result for another design.

Related Information

Advanced Fitter Setting Dialog Box Help Topic
In *Quartus Prime Help*

5.5.4.1. Optimize Hold Timing

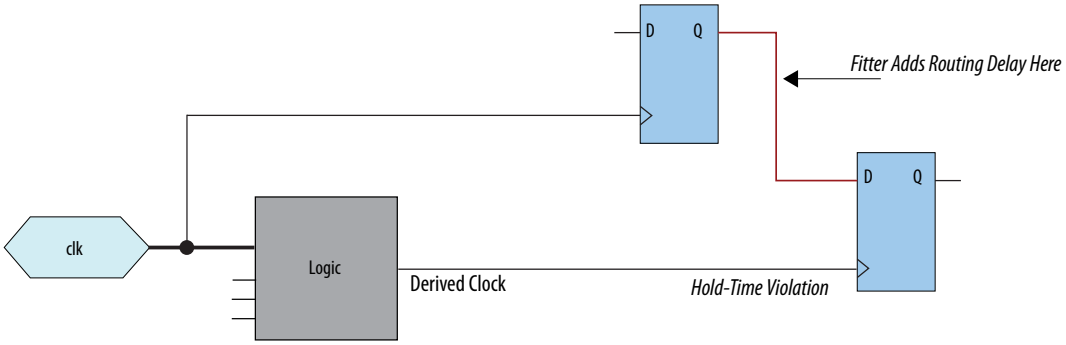
The **Optimize Hold Timing** option directs the Quartus Prime software to optimize minimum delay timing constraints.

When you turn on **Optimize Hold Timing** in the **Advanced Fitter Settings** dialog box, the Quartus Prime software adds delay to paths to ensure that your design meets the minimum delay requirements. If you select **I/O Paths and Minimum TPD Paths**, the Fitter works to meet the following criteria:

- Hold times (t_H) from the device input pins to the registers
- Minimum delays from I/O pins to I/O registers or from I/O registers to I/O pins
- Minimum clock-to-out time (t_{CO}) from registers to output pins

If you select **All Paths**, the Fitter also works to meet hold requirements from registers to registers, as highlighted in blue in the figure, in which a derived clock generated with logic causes a hold time problem on another register.

Figure 59. Optimize Hold Timing Option Fixing an Internal Hold Time Violation



However, if your design still has internal hold time violations between registers, you can manually add delays by instantiating LCELL primitives, or by making changes to your design, such as using a clock enable signal instead of a derived or gated clock.

Quartus Prime Pro Edition User Guide: Design Recommendations

5.5.4.2. Fitter Aggressive Routability Optimization

The **Fitter Aggressive Routability Optimizations** logic option allows you to specify whether the Fitter aggressively optimizes for routability. Performing aggressive routability optimizations may decrease design speed, but may also reduce routing wire usage and routing time.

This option is useful if routing resources are resulting in no-fit errors, and you want to reduce routing wire use.

The table lists the settings for the **Fitter Aggressive Routability Optimizations** logic option.

Table 27. Fitter Aggressive Routability Optimizations Logic Option Settings

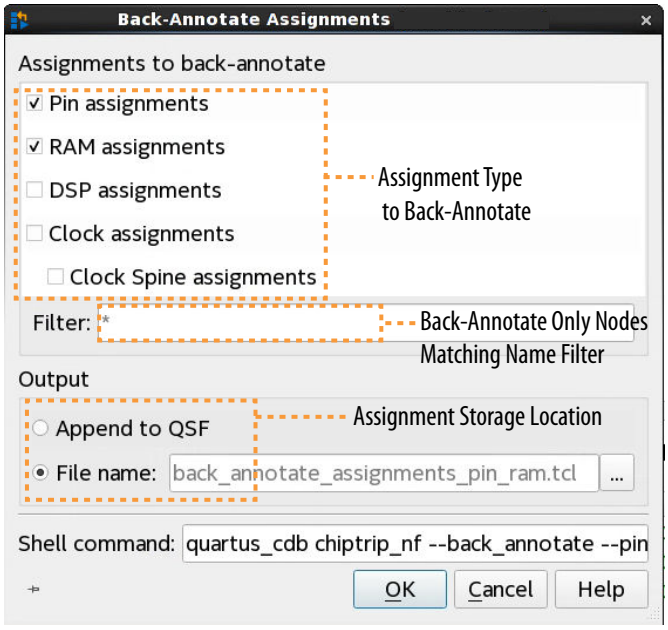
Settings	Description
Always	The Fitter always performs aggressive routability optimizations. If you set the **Fitter Aggressive Routability Optimizations** logic option to **Always**, reducing wire utilization may affect the performance of your design.
Never	The Fitter never performs aggressive routability optimizations. If improving timing is more important than reducing wire usage, then set this option to **Automatically** or **Never**.
Automatically	The Fitter performs aggressive routability optimizations automatically, based on the routability and timing requirements of the design. If improving timing is more important than reducing wire usage, then set this option to **Automatically** or **Never**.

5.5.5. Back-Annotating Optimized Assignments

The Compiler maps the elements of your design to specific device resources during fitting. After compilation, you can back-annotate (copy) the Compiler's resource assignments to preserve that same implementation in subsequent compilations. Back-annotation can simplify timing closure by allowing you to lock down placement of your optimized results.

Locking down placement of large blocks related to Clocks, RAMs, and DSPs can produce higher f_{MAX} with less noise. Large blocks like RAMs and DSPs have heavier connectivity than regular LABs, complicating movement during placement. When a seed produces good results from suitable RAM and DSP placement, you can capture that placement with back-annotation. Subsequent compiles can then benefit from the high quality RAM and DSP placement from the good seed.

Figure 60. Back-Annotate Assignments Dialog Box



To back-annotate (copy) the device resource assignments from the last compilation to the project `.qsf` (or to a Tcl file) for use in the next compilation:

1. Run a full compilation, or run the Fitter through at least the **Place** stage.
2. Click **Assignments ➤ Back-Annotate Assignments**.
3. Under **Assignments to back-annotate**, specify whether you want to preserve **Pin assignments**, **RAM assignments**, **DSP assignments**, **Clock assignments**, and **Clock Spine assignments** in the back-annotation.
4. In **Filter**, specify a text string (including wildcards) if you want to filter back-annotated assignments by entity name.
5. Under **Output**, specify whether to save the back-annotated assignments to the `.qsf` or to a Tcl file. A default Tcl file name displays.

Alternatively, you can run back-annotation with the following `quartus_cdb` executable. The **Shell command** field displays the shell command constructed by the options that you specify in the GUI.

```
quartus_cdb chiptrip_nf --back_annotate --pin --ram --dsp --clocks \
    --spines --file "<file>.tcl"
```

Note: Check available arguments by running `quartus_cdb <project> --back_annotate --help`.

5.5.6. Optimize Settings with Design Space Explorer II

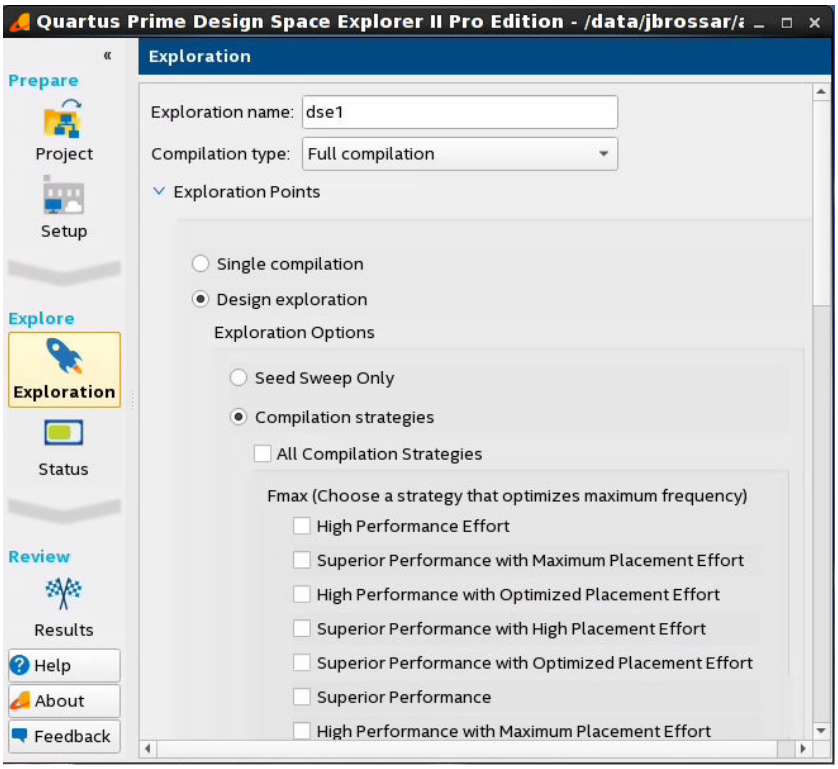
The Design Space Explorer II tool (**Tools ➤ Launch Design Space Explorer II**) allows you to find optimal project settings for resource, performance, or power optimization goals. Design Space Explorer II (DSE II) processes a design using combinations of settings and constraints, and reports the best combination of settings and constraints for the design. You can also take advantage of the DSE II parallelization abilities to compile on multiple computers.

In DSE II, an *exploration point* is a collection of Analysis & Synthesis, Fitter, and placement settings, and a group of exploration points is a *design exploration*. A design exploration can also include different fitter seeds.

DSE II compiles the design using the settings corresponding to each exploration point. When the compilation finishes, DSE II evaluates the performance data against an optimization goal that you specify. You can direct the DSE II to optimize for timing, area, or power.

If a design is close to meeting timing or area requirements, you can try different seeds with the DSE II, and find one seed that meets timing or area requirements.

Figure 61. Design Space Explorer II



You can run DSE II at any step in the design process; however, because large changes in a design can neutralize gains achieved from optimizing settings, Intel FPGA recommends that you run DSE II late in the design cycle.

Note: When comparing the results of different seed sweeps with DSE II, changing any of the following variables can cause differences in the compilation results between seed sweeps, resulting in a somewhat different fit in each case:

- The number or type of CPUs that DSE II uses to perform the seed sweeps
- Any change to the operating system
- Any change to source file content or location
- Any change to the Compiler settings or Timing Analyzer settings

For more information, refer to Fitter Seed on page 127.

Related Information

Using Design Space Explorer
21 Minute Online Course

5.5.6.1. DSE II Computing Resources

You can configure DSE II to take advantage of your computing resources to run the design explorations. In the DSE II GUI, the **Setup** page contains the job launch options, and the **Status** page allows you to monitor and control jobs.

DSE II supports running compilations on your local computer or a remote host through LSF, SSH or Torque. For SSH, you can also define a comma-separated list of remote hosts.

If you have a laptop or standard computer, you can use the single compilation feature to compile your design on a workstation with higher computing performance and memory capacity.

When running on a compute farm, you can direct the DSE II to safely exit after submitting all the jobs while the compilations continue to run until completion. Optionally, you can receive an e-mail when the compilations are complete.

If you launch jobs using SSH, the remote host must enable public and private key authentication. For private keys encrypted with a pass phrase, the remote host must run the ssh key agent to decrypt the private key, so the `quartus_dse` executable can access the key.

Note: Windows remote hosts require Cygwin's sshd server and PuTTY.

5.5.6.2. DSE II Optimization Parameters

DSE II provides a collection of predefined exploration spaces that focus on what you want to optimize. Additionally, you can define a set of compilation seeds. The number of explorations points is the number of seeds multiplied by the number of exploration modes.

Note: The availability of predefined spaces depends on the device family that the design targets.

In the DSE GUI, you specify these settings in the **Exploration** page.

Related Information

Exploration Page (Design Space Explorer II)
In *Quartus Prime Help*

5.5.6.3. DSE II Result Management

DSE II compares the compilation results to determine the best Quartus Prime software settings for the design. The **Report** page displays a summary of results.

In an exploration, DSE II selects the best worst-case slack value from among all timing corners across all exploration points. If you want to optimize for worst-case setup slack or hold slack, specify timing constraints in the Quartus Prime software.

Disk Space

By default, DSE II saves all the compilation data. You can save disk space by limiting the type of files that you want to save after a compilation finishes. These settings are in the **Exploration** page, **Results** section.

Reports

DSE II has reporting tools that help you quickly determine important design metrics, such as worse-case slack, across all exploration points.

DSE II provides a performance data report for all points it explores and saves the information in a `project-name.dse.rpt` file in the project directory. DSE II archives the settings of the exploration points in Quartus Prime Archive Files (`.qar`).

Related Information

Report Page (Design Space Explorer II)
In *Quartus Prime Help*

5.5.6.4. Running DSE II

Note: Before running DSE II, specify the timing constraints for the design.

This description covers the type of settings that you need to define when you want to run a design exploration. For details about all the options available in the GUI, refer to the Quartus Prime Help.

To perform a design exploration with the DSE II tool:

1. Start the DSE II tool.

   If you have an open project in the Quartus Prime software and launch DSE II, a dialog box appears asking if you want to close the Quartus Prime software. Click **Yes**.
2. In the **Project** page, specify the project and revision that you want to explore.
3. In the **Setup** page, specify whether you want to perform a local or a remote exploration, and set up the job launch.
4. In the **Exploration** page, specify optimization settings and goals.
5. When the configuration is complete, click **Start**.

5.5.7. Aggregating and Comparing Compilation Results with Exploration Dashboard

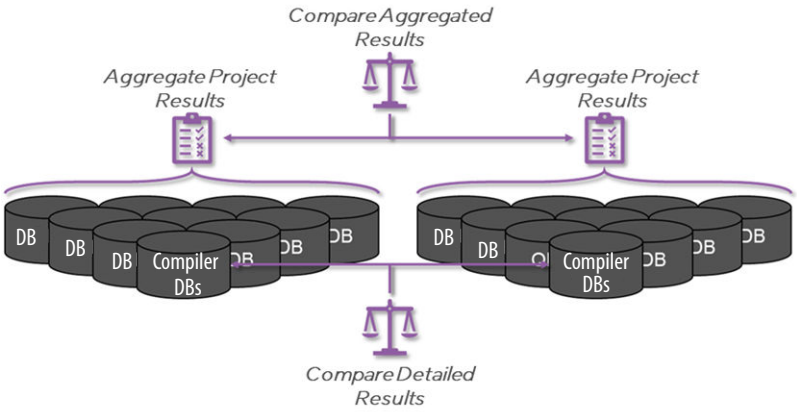
You can use the Exploration Dashboard (`quartus_edw`) in the Quartus Prime Pro Edition software to aggregate and compare compilation results between multiple Quartus Prime projects or sets of compilation results.

The Exploration Dashboard allows you to easily coordinate and view the compilation and timing results from multiple projects running on separate instances of the Quartus Prime software. For example, you can analyze and compare versions of the same design that differ by RTL changes, or perhaps only differ by project settings. The Exploration Dashboard provides the power and flexibility to support multi-project analysis for a diverse range of work flows and analysis tasks.(1)

The Exploration Dashboard interfaces with multiple Quartus Prime projects simultaneously in a single workspace to help you close timing by aggregating and comparing results from multiple seeds or multiple versions of your design.

- Aggregating compilation results—Exploration Dashboard reports what is common in all the compilation results for a version of your design.
- Comparing compilation results—Exploration Dashboard reports the differences between different versions of your design.

Figure 62. Exploration Dashboard Use Model



Use the Exploration Dashboard to quickly compare the aggregated compilation results from multiple projects or sets of results to determine the best implementation and impact of changes. The Exploration Dashboard supports use cases like the following:

- Identify all of the failing timing paths, in all seeds, after completing a seed sweep.
- Determine whether the average f_{MAX} improves after RTL optimization.
- Track a scorecard of design performance as the project proceeds towards completion.
- Compare compilation results across Quartus Prime software versions.

(1) Exploration Dashboard is pre-production status in Quartus Prime Pro Edition v.24.1, and supports analysis of compilation results generated with Quartus Prime Pro Edition software version 21.1 through version 24.1. Other versions may function but are not verified.

For example, you can use Exploration Dashboard to report timing on all of your various compilation seeds, and view the path from all seeds in a single report view. Exploration dashboard allows you to compare historical results against new data. This allows you to track improvement over time on critical design metrics, such as Fmax and power.

The Exploration Dashboard is currently a Tcl-based API that employs an object-property model to aggregate and compare objects across multiple compilation databases that store results from your different compilations.

Note: For a step-by-step tutorial using the Exploration Dashboard GUI and an example design, refer to *AN 1006: Multi-Project Analysis with Exploration Dashboard*.

Related Information

AN 1006: Multi-Project Analysis with Exploration Dashboard

5.5.7.1. Aggregation Use Case

Aggregation helps you see all the results from your compiles in one workspace. For example, you can use aggregation to determine whether particular timing failures occur commonly or occasionally. Focusing your optimization work on failures that occur commonly has higher impact than focusing on failures that occur occasionally.

Aggregation is helpful because of the stochastic nature of the Quartus Prime Compiler. This stochastic nature means that the Compiler employs random heuristics in some decision-making processes. These heuristics perform well on average, but certain sequences can have unusually good or bad outcomes.

Often, the seed value that governs these random decisions is a project input that you can change to explore for a given design without changing the design. Because these random decisions are sensitive to specific netlist topologies, constraints, and design file content ordering, various different project element changes can result in the "seed effect" without any meaningful change to the design. Therefore, any given compilation result is not a precise measure of the quality of the design. While an individual compilation is the only source of programming files, you can run multiple compilations with different seed values in parallel, with each project containing its own seed value, to obtain the best results.

When performing aggregation, you are usually looking for common trends and limitations among the results. Since the compiles that you analyze with aggregation are different compilations of the exact same design, any random differences between the projects should cancel out, and any fundamental issues should recur.

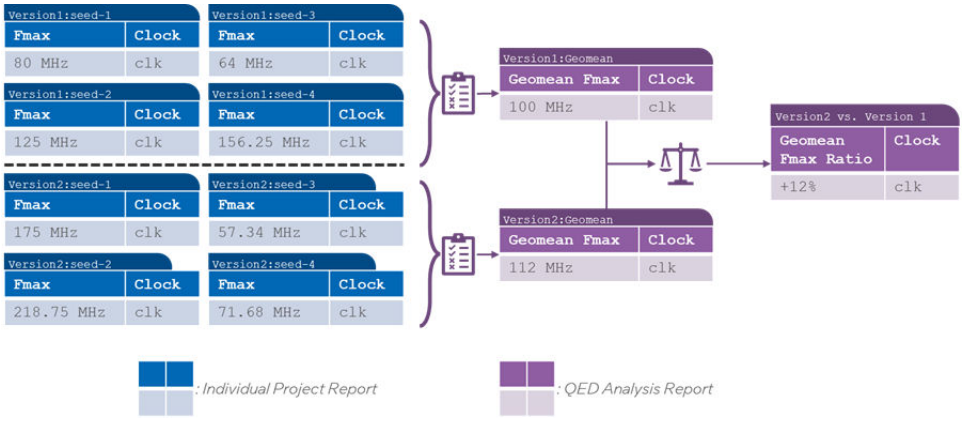
Nevertheless, there can be certain projects and seeds that are outliers. You can then compare to the aggregate of the remaining projects. You can use this method to either explain unusually good or unusually bad results in the outlier projects in comparison with typical results.

5.5.7.2. Comparison Use Case

Comparison of compilation results can be helpful in determining the set of conditions or properties that are different between two sets of compilation results. For example, you can compare the differences between sets of compilation results that you generate at different times from the similar source files. From the perspective of the Quartus Prime Compiler, such projects are technically different. You can also export Exploration Dashboard results for further mathematical analysis in other tools.

Comparison allows you to determine whether certain design changes result in the compilation results that you want. You can compare the aggregate-before results to the aggregate-after results. Exploration Dashboard can analyze multiple seeds of each version of the design together first, and then compare the common results across versions of the design. In comparison use cases, the goal is to decide if the design changes made the design better or worse overall.

Figure 63. Visualization of Fmax Aggregation and Comparison Analysis



Visualization of Fmax Aggregation and Comparison Analysis illustrates an example of aggregation followed by comparison. In this example use-case:

1. The designer first compiles “Version1” of their design four times through four different seed values.
2. The designer next makes some changes to the design for “Version2”.
3. The designer compiles “Version2” four times.

To determine if the “Version2” design changes improve the design performance overall, the designer can follow these steps:

1. Aggregate the Fmax results from each version by taking the geometric mean (geomean) of the Fmax across seeds.
2. Compare the geomean values and conclude that “Version2” has an expected +12% improvement to Fmax compared to "Version1".

The Exploration Dashboard is instrumental in this comparison because no other individual seed versus seed comparison can show this result. Comparison of the individual compilation results can lead to a different conclusion.

5.5.7.3. Exploration Dashboard Object-Property Model

The Exploration Dashboard operates on an object-property model that defines the following roles, responsibilities, and properties of the major object types:

Figure 64. Visualization of the Objects in the Exploration Dashboard Environment

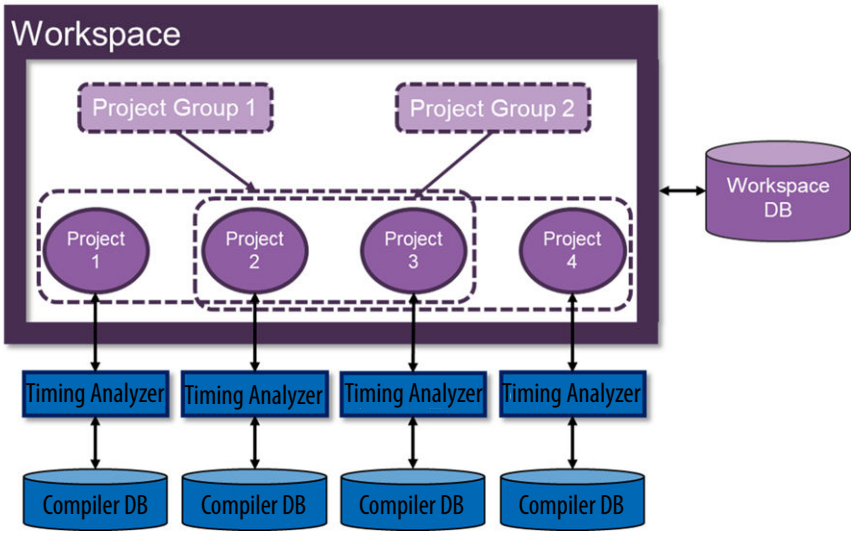


Table 28. Exploration Dashboard Terms

Term	Description
Workspace	The workspace is a single container for all other Exploration Dashboard objects, reports, and results. The workspace governs all persistence, namespace, and portability requirements of Exploration Dashboard flows. The properties of the workspace govern global settings and behaviors that do not pertain to any individual group or project.
Project Handle	Corresponds 1:1 with a Compiler database and the necessary configurations to access it. The purpose of the Project Handle is to launch a new Quartus Prime software process and send commands and data back and forth over a communication channel.
Project Group	Provides a method to refer to and work with an arbitrary subset of the Project Handles that are loaded in the workspace. Each project group can contain any number of projects. Each project ID present in a group's projects property corresponds to a project object that is guaranteed to have that group's ID present in its groups property.
Compiler database	The database that preserves the compilation results from one previous run of the Compiler.

Note: For the complete Exploration Dashboard Tcl API, refer to *::quartus::qed* in the *Quartus Prime Pro Edition User Guide: Scripting*.

Related Information

::quartus::qed, Quartus Prime Pro Edition User Guide: Scripting

5.5.7.3.1. Base Exploration Dashboard Properties

This section describes the Exploration Dashboard objects and properties that you can configure and use for aggregating and comparing compilation results in the Exploration Dashboard.

The following base objects and properties are common across all objects and accessible using `set_property` and `get_property`.

Table 29. Base Exploration Dashboard Objects and Properties

Property Name	Property Type	Property Description	Default Value	Read-Only	Comments
`type`	Either: `project`, `group`, or `workspace`	Type of the object	N/A (must be specified)	True	
`id`	string	Identifier associated with the object	Automatically generated based on the `type` (for example, `project_1`)		All IDs must be globally unique within a Workspace. Constructing an object causes an error if you specify an ID that is already allocated to another object.
`user_data`	string	Arbitrary data you want to store	N/A		You can optionally access `user_data` using methods described below.

::qed::set_user_data and ::qed::get_user_data Specializations

In addition to `set_property` and `get_property` `user_data` also supports the `set_user_data` and `get_user_data` specializations for access. These specializations allow for more convenience when using the recommended (but unrequired) method of managing `user_data` like a Tcl dictionary.

For example, you can use the `qed::get_property` command to retrieve the value of the `user_data` property. You could then treat it as a `dict` and use `dict get` or `dict set` commands to manipulate the value, and optionally store any changes with the `qed::set_property command`.

The following shows equivalent examples using the two methods discussed:

```
::qed::get_user_data <object> -key <key>
```

is equivalent to:

```
set tmp [::qed::get_property <object> -property user_data]
dict get $tmp <key>
```

Similarly,

```
::qed::set_user_data <object> -key <key> -value <value>
```

is equivalent to:

```
set tmp [qed::get_property <object> -property user_data]
dict set tmp <key> <value>
::qed::set_property <object> -property user_data -value $tmp
```

5.5.7.3.2. Project Handle Properties

The main purpose of Project Handle objects is to configure, launch, and manage a connection to a single project compilation database.

Table 30. Project Handle Properties

Property Name	Property Type	Property Description	Default Value	Read-Only	Comments
`qpf_path`	String (must be a valid path to a `.qpf` file)	Project file corresponding to the project and database to open and interface with	N/A		
`project_directory`	String	Directory name of the project file you interface with	N/A	True	Derived from the `qpf_path` value
`project_name`	String	Base name of the project file being interfaced with	N/A	True	Derived from the `qpf_path` value
`revision_name`	String	Revision name to specify	N/A		If unspecified, Exploration Dashboard assumes that the revision name is the default revision name for the project. This updates when you set the `qpf_path` property.
`connection_status`	Enum	Reflects the state of the communication channel after the `launch_connection` or `disconnect` methods complete successfully.	`CLOSED`	True	Can be one of `STARTING`, `READY`, `CLOSED`, `RUNNING`, `TIMEOUT`, or `ANY`
`groups`	List of Project Group IDs	Set of groups to which the project belongs.	N/A		A project can be in any number of groups. Each group ID present in a project's `groups` property corresponds to a group object that is guaranteed to have that project's ID present in its `projects` property . Project `groups` properties are kept consistent with group `projects` properties). *Note:* All projects must be in at least one group. Running `sanitize_workspace` creates and places all ungrouped projects into a default group.
`db_state`	Enum	Indicates whether the project's compilation database is loaded or not	`Unloaded`	True	Can be one of `unloaded` or `loaded`.

5.5.7.3.3. Project Group Objects and Properties

The main purpose of a Project Group is to provide a convenient way to refer to and work with an arbitrary subset of the Project Handles that are loaded in the workspace.

Table 31. Project Group Objects and Properties

Property Name	Property Type	Property Description	Default Value	Read-Only	Comments
`projects`	List of Project Group IDs	Set of projects belonging to the group	N/A		A group can contain any number of projects. Each project ID present in a group's `projects` property corresponds to a project object that is guaranteed to have that group's ID present in its `groups` property (group `projects` properties are kept consistent with project `groups` properties).

5.5.7.3.4. Workspace Objects and Properties

The main purpose of a workspace is to act as a single container for all other Exploration Dashboard objects, reports, and results. The workspace also handles persistence, namespace, and portability for Exploration Dashboard flows.

Table 32. Workspace Objects and Properties

Property Name	Property Type	Property Description	Default Value	Read-Only	Comments
`default_group_id`	Valid Group ID	ID of the default group that `sanitize_workspace` uses to ensure all projects are placed in at least one group.	`default_group_1`		The default group ID is reserved upon workspace construction, but the default group itself isn't constructed until required by `sanitize_workspace`. You can modify this property to designate a specific group as the default group for un-grouped projects.

5.5.7.4. Starting the Exploration Dashboard

To start the Exploration Dashboard using the Tcl API, follow these steps:

1. To start the Exploration Dashboard, perform one of the following:
   - To start Exploration Dashboard in shell mode with the Quartus Prime Pro Edition software, type the following command:
     ```
     quartus_ed -s
     ```
   - To start the Exploration Dashboard in GUI mode with the Quartus Prime Pro Edition software, type the following command:
     ```
     quartus_edw
     ```
2. To create a group in the workspace, type the following command and specify a group name:
   ```
   ::qed::create_object -type group <group name>
   ```
3. To add project objects to the workspace for exploration, type the following command to specify the type of object (project), a unique ID (for example based on the `seednumber`), and the path to the `.qpf` file:
   ```
   ::qed::create_object -type <project|group> -qpf_path <qpf path> <id>
   ```
   The following commands show examples of this syntax:
   ```
   ::qed::create_object -type project -qpf_path ../seed2/top.qpf seed2
   ```
   The Exploration Dashboard creates the `id` if unspecified. Repeat this step for each project object that you want to add to the workspace for aggregation and comparison.
4. To perform workspace legality checks and modify the state of your workspace to make it legal, type the following command:
   ```
   qed::sanitize_workspace
   ```

The Exploration Dashboard is ready to receive other commands to analyze, aggregate, and compare the compilations results from the project objects in the workspace. For the complete Exploration Dashboard Tcl API, search for *::quartus::qed* in the *Quartus Prime Pro Edition User Guide: Scripting*.

Note: For a step-by-step tutorial using the Exploration Dashboard GUI and an example design, refer to *AN 1006: Multi-Project Analysis with Exploration Dashboard*.

5.5.8. I/O Timing Optimization Techniques

This stage of design optimization focuses on I/O timing, including setup delay (t_{SU}), hold time (t_H), and clock-to-output (t_{CO}) parameters.

Before proceeding with I/O timing optimization, ensure that:

- The design's assignments follow the suggestions in the *Initial Compilation: Required Settings* section of the *Design Optimization Overview* chapter.
- Resource utilization is satisfactory.

Note: Complete this stage before proceeding to the register-to-register timing optimization stage. Changes to the I/O paths affect the internal register-to-register timing.

Summary of Techniques for Improving Setup and Clock-to-Output Times

The table lists the recommended order of techniques to reduce t_{SU} and t_{CO} times. Reducing t_{SU} times increases hold (t_H) times.

Note: Verify which options are available to each device family

Table 33. Improving Setup and Clock-to-Output Times

Order	Technique	Affects t_{SU}	Affects t_{CO}
1	Verify of that the appropriate constraints are set for the failing I/Os (refer to *Initial Compilation: Required Settings*)	Yes	Yes
2	Use timing-driven compilation for I/O (refer to *Fast Input, Output, and Output Enable Registers*)	Yes	Yes
3	Use fast input register (refer to *Programmable Delays*)	Yes	N/A
4	Use fast output register, fast output enable register, and fast OCT register (refer to *Programmable Delays*)	N/A	Yes
5	Decrease the value of **Input Delay from Pin to Input Register** or set **Decrease Input Delay to Input Register = ON**	Yes	N/A
6	Decrease the value of **Input Delay from Pin to Internal Cells** or set **Decrease Input Delay to Internal Cells = ON**	Yes	N/A
7	Decrease the value of **Delay from Output Register to Output Pin** or set **Increase Delay to Output Pin = OFF** (refer to *Fast Input, Output, and Output Enable Registers*)	N/A	Yes
8	Increase the value of **Input Delay from Dual-Purpose Clock Pin to Fan-Out Destinations** (refer to *Fast Input, Output, and Output Enable Registers*)	Yes	N/A
9	**Use PLLs to shift clock edges**	Yes	Yes
10	Increase the value of **Delay to output enable pin** or set **Increase delay to output enable pin** (refer to *Use PLLs to Shift Clock Edges*)	N/A	Yes

5.5.8.1. I/O Timing Constraints

Timing Analyzer supports the Synopsys* Design Constraints (SDC) format for constraining your design. When using the Timing Analyzer for timing analysis, use the `set_input_delay` constraint to specify the data arrival time at an input port with respect to a given clock. For output ports, use the `set_output_delay` command to specify the data arrival time at an output port's receiver with respect to a given clock. You can use the `report_timing` Tcl command to generate the I/O timing reports.

The I/O paths that do not meet the required timing performance are reported as having negative slack and are highlighted in red in the Timing Analyzer **Report** pane. In cases where you do not apply an explicit I/O timing constraint to an I/O pin, the Quartus Prime timing analysis software still reports the **Actual** number, which is the timing number that must be met for that timing parameter when the device runs in your system.

Related Information

Quartus Prime Pro Edition User Guide: Timing Analyzer

5.5.8.2. Optimize IOC Register Placement for Timing Logic Option

This option moves registers into I/O elements to meet t_{SU} or t_{CO} assignments, duplicating the register if necessary (as in the case in which a register fans out to multiple output locations). This option is turned on by default and is a global setting.

The **Optimize IOC Register Placement for Timing** logic option affects only pins that have a t_{SU} or t_{CO} requirement. Using the I/O register is possible only if the register directly feeds a pin or is fed directly by a pin. Therefore, this logic option does not affect registers with any of the following characteristics:

Note: To optimize registers with these characteristics, use other Quartus Prime Fitter optimizations.

- Have combinational logic between the register and the pin
- Are part of a carry chain
- Have an overriding location assignment
- Use the asynchronous load port and the value is not 1 (in device families where the port is available)

Related Information

Optimize IOC Register Placement for Timing Logic Option Help Topic
In *Quartus Prime Help*

5.5.8.3. Fast Input, Output, and Output Enable Registers

You can place individual registers in I/O cells manually by making fast I/O assignments with the Assignment Editor. By default, with correct timing assignments, the Fitter places the I/O registers in the correct I/O cell or in the core, to meet the performance requirement.

If the fast I/O setting is on, the register is always placed in the I/O element. If the fast I/O setting is off, the register is never placed in the I/O element. This is true even if the **Optimize IOC Register Placement for Timing** option is turned on. If there is

no fast I/O assignment, the Quartus Prime software determines whether to place registers in I/O elements if the **Optimize IOC Register Placement for Timing** option is turned on.

You can also use the four fast I/O options (**Fast Input Register**, **Fast Output Register**, **Fast Output Enable Register**, and **Fast OCT Register**) to override the location of a register that is in a Logic Lock region and force it into an I/O cell. If you apply this assignment to a register that feeds multiple pins, the Fitter duplicates the register and places it in all relevant I/O elements.

For more information about the **Fast Input Register** option, **Fast Output Register** option, **Fast Output Enable Register** option, and **Fast OCT (on-chip termination) Register** option, refer to Quartus Prime Help.

5.5.8.4. Programmable Delays

You can use various programmable delay options to minimize the t_{SU} and t_{CO} times. Programmable delays are advanced options that you use only after you compile a project, check the I/O timing, and determine that the timing is unsatisfactory.

The Quartus Prime software automatically adjusts the applicable programmable delays to help meet timing requirements. For detailed information about the effect of these options, refer to the device family handbook or data sheet.

After you have made a programmable delay assignment and compiled the design, you can view the implemented delay values for every delay chain and every I/O pin in the **Delay Chain Summary** section of the Compilation Report.

You can assign programmable delay options to supported nodes with the Assignment Editor. You can also view and modify the delay chain setting for the target device with the Chip Planner and Resource Property Editor. When you use the Resource Property Editor to make changes after performing a full compilation, recompiling the entire design is not necessary; you can save changes directly to the netlist. Because these changes are made directly to the netlist, the changes are not made again automatically when you recompile the design. The change management features allow you to reapply the changes on subsequent compilations.

Although the programmable delays in newer devices are user-controllable, Intel recommends their use for advanced users only. However, the Quartus Prime software might use the programmable delays internally during the Fitter phase.

For details about the programmable delay logic options available for Intel devices, refer to the following Quartus Prime Help topics:

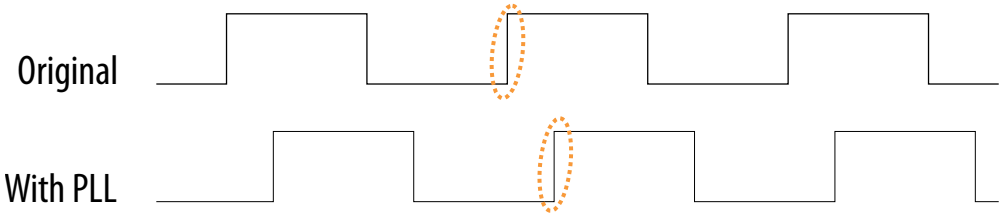
5.5.8.5. Use PLLs to Shift Clock Edges

Using a PLL typically improves I/O timing automatically. If the timing requirements are still not met, most devices allow the PLL output to be phase shifted to change the I/O timing. Shifting the clock backwards gives a better t_H at the expense of t_{SU}, while shifting it forward gives a better t_{SU} at the expense of t_H. You can use this technique only in devices that offer PLLs with the phase shift option.

Figure 65. Shift Clock Edges Forward to Improve t_{SU} at the Expense of t_H



You can achieve the same type of effect in certain devices by using the programmable delay called **Input Delay from Dual Purpose Clock Pin to Fan-Out Destinations**.

5.5.8.6. Use Fast Regional Clock Networks and Regional Clocks Networks

Regional clocks provide the lowest clock delay and skew for logic contained in a single quadrant. In general, fast regional clocks have less delay to I/O elements than regional and global clocks, and are used for high fan-out control signals. Placing clocks on these low-skew and low-delay clock nets provides better t_{CO} performance.

Intel devices have a variety of hierarchical clock structures. These include dedicated global clock networks, regional clock networks, fast regional clock networks, and periphery clock networks. The available resources differ between the various Intel device families.

For the number of clocking resources available in your target device, refer to the appropriate device handbook.

5.5.8.7. Spine Clock Limitations

In Arria 10 and Cyclone 10 GX designs with high clock routing demands, limitations in the Quartus Prime software can cause spine clock errors. These limits do not apply to Stratix 10 or Agilex 7 designs.

These errors can occur with designs using multiple memory interfaces and high-speed serial interface (HSSI) channels, especially with PMA Direct mode.

Global clock networks, regional clock networks, and periphery clock networks have an additional level of clock hierarchy known as spine clocks. Spine clocks drive the final row and column clocks to their registers; thus, the clock to every register in the chip is reached through spine clocks. Spine clocks are not directly user controllable.

To reduce these spine clock errors, constrain your design to use your regional clock resources better:

- If your design does not use Logic Lock regions, or if the Logic Lock regions are not aligned to your clock region boundaries, create additional Logic Lock regions and further constrain your logic.
- To ensure that the global promotion process uses the correct locations, assign specific pins to the I/Os using these periphery features.
- By default, some Intel FPGA IP functions apply a global signal assignment with a value of dual-regional clock. If you constrain your logic to a regional clock region and set the global signal assignment to **Regional** instead of **Dual-Regional**, you can reduce clock resource contention.

Related Information

Viewing Available Clock Networks in Chip Planner on page 149

5.5.9. Register-to-Register Timing Optimization Techniques

The next stage of design optimization seeks to improve register-to-register (f_{MAX}) timing. The following sections provide available options if the design does not meet timing requirements after compilation.

Coding style affects the performance of a design to a greater extent than other changes in settings. Always evaluate the code and make sure to use synchronous design practices.

Note: In the context of the Timing Analyzer, register-to-register timing optimization is the same as maximizing the slack on the clock domains in a design. The techniques in this section can improve the slack on different timing paths in the design.

Before performing design optimizations, understand the structure of the design as well as the effects of techniques in different types of logic. Techniques that do not benefit the logic structure can decrease performance.

Related Information

- Design Assistant Rules List

5.5.9.1. Optimize Source Code

In many cases, optimizing the design's source code can have a very significant effect on your design performance. In fact, optimizing your source code is typically the most effective technique for improving the quality of your results and is often a better choice than using Logic Lock or location assignments.

You can use the Design Assistant to help identify areas in the design for timing optimization. Be aware of the number of logic levels needed to implement your logic while you are coding. Too many levels of logic between registers might result in critical paths failing timing. Try restructuring the design to use pipelining or more efficient coding techniques. Also, try limiting high fan-out signals in the source code. When possible, duplicate and pipeline control signals. Make sure the duplicate registers are protected by a preserve attribute, to avoid merging during synthesis.

If the critical path in your design involves memory or DSP functions, check whether you have code blocks in your design that describe memory or functions that are not being inferred and placed in dedicated logic. You might be able to modify your source code to cause these functions to be placed into high-performance dedicated memory or resources in the target device. When using RAM/DSP blocks, enable the optional input and output registers.

Ensure that your state machines are recognized as state machine logic and optimized appropriately in your synthesis tool. State machines that are recognized are generally optimized better than if the synthesis tool treats them as generic logic. In the Quartus Prime software, you can check the State Machine report under **Analysis & Synthesis** in the Compilation Report. This report provides details, including state encoding for each state machine that was recognized during compilation. If your state machine is not recognized, you might have to change your source code to enable it to be recognized.

5.5.9.2. Improving Register-to-Register Timing

The choice of options and settings to improve the timing margin (slack) or to improve register-to-register timing depends on the failing paths in the design. To achieve the results that best approximate your performance requirements, apply the following techniques and compile the design after each step:

1. Ensure that your timing assignments are complete and correct. For details, refer to the *Initial Compilation: Required Settings* section in the *Design Optimization Overview* chapter.
2. Review all Design Assistant rule violations and other warning messages from your initial compilation and check for ignored timing assignments. Design Assistant helps to identify and correct any invalid timing constraints.
3. Apply netlist synthesis optimization options.
4. To optimize for speed, apply the following synthesis options:
   - Optimize Synthesis for Speed, Not Area
   - Flatten the Hierarchy During Synthesis
   - Set the Synthesis Effort to High
   - Prevent Shift Register Inference
   - Use Other Synthesis Options Available in Your Synthesis Tool
5. To optimize for performance, turn on Advanced Physical Optimization
6. Try different Fitter seeds. If only a small number of paths are failing by small negative slack, then you can try with a different seed to find a fit that meets constraints in the Fitter seed noise.

   Note: Omit this step if a large number of critical paths are failing, or if the paths are failing by a long margin.

7. To control placement, make Logic Lock assignments.
8. Modify your design source code to fix areas of the design that are still failing timing requirements by significant amounts.
9. Make location assignments, or as a last resort, perform manual placement by back-annotating the design.

   You can use Design Space Explorer II (DSE) to automate the process of running different compilations with different settings.

   If these techniques do not achieve performance requirements, additional design source code modifications might be required.

Related Information

- Optimize Settings with Design Space Explorer II on page 102
- Initial Compiler Settings on page 7

5.5.9.3. Physical Synthesis Optimizations

The Quartus Prime software offers physical synthesis optimizations that can help improve design performance regardless of the synthesis tool. You can apply physical synthesis optimizations both during synthesis and during fitting.

During the synthesis stage of the Quartus Prime compilation, physical synthesis optimizations operate either on the output from another EDA synthesis tool, or as an intermediate step in synthesis. These optimizations modify the synthesis netlist to improve either area or speed, depending on the technique and effort level you select.

To view and modify the synthesis netlist optimization options, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**.

If you use a third-party EDA synthesis tool and want to determine if the Quartus Prime software can remap the circuit to improve performance, use the **Perform WYSIWYG Primitive Resynthesis** option. This option directs the Quartus Prime software to un-map the LEs in an atom netlist to logic gates, and then map the gates back to Intel-specific primitives. Intel-specific primitives enable the Fitter to remap the circuits using architecture-specific techniques.

The Quartus Prime Compiler optimizes the design to achieve maximum speed performance, minimum area usage, or balances high performance and minimal logic usage, according to the setting of the **Optimization Technique** option. Set this option to **Speed** or **Balanced**.

During the Fitter stage of the Quartus Prime compilation, physical synthesis optimizations make placement-specific changes to the netlist that improve speed performance results for the specific Intel device.

  In *Quartus Prime Help*

5.5.9.4. Set Power Optimization During Synthesis to Normal Compilation

The default value for the Compiler's **Power Optimization During Synthesis** setting is **Normal Compilation**. However, if **Power Optimization During Synthesis** is set to **Extra Effort**, design performance can be affected. To avoid any possible effect, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Power Optimization During Synthesis** to confirm the **Normal Compilation** setting value.

Related Information

Power Optimization

5.5.9.5. Optimize Synthesis for Performance, Not Area

Design performance varies depending on coding style, synthesis tool used, and options you specify when synthesizing. Change your synthesis options if a large number of paths are failing, or if specific paths fail by a great margin and have many levels of logic.

Identify the default optimization targets of your Synthesis tool, and set your device and timing constraints accordingly. For example, if you do not specify a target frequency, some synthesis tools optimize for area.

Optimize for performance by specifying the **High Performance Effort**, **High Performance with Maximum Placement Effort**, **High Performance with Aggressive Power Effort**, **Superior Performance**, or **Superior Performance with Maximum Placement Effort** optimization mode.

Related Information

Optimization Technique Logic Option Help Topic
In *Quartus Prime Help*

5.5.9.6. Flatten the Hierarchy During Synthesis

Synthesis tools typically let you preserve hierarchical boundaries, which can be useful for verification or other purposes. However, the best optimization results generally occur when the synthesis tool optimizes across hierarchical boundaries, because doing so often allows the synthesis tool to perform the most logic minimization, which can improve performance. Whenever possible, flatten your design hierarchy to achieve the best results.

5.5.9.7. Set the Synthesis Effort to High

Synthesis tools offer varying synthesis effort levels to trade off compilation time with synthesis results. Set the synthesis effort to **high** to achieve best results when applicable.

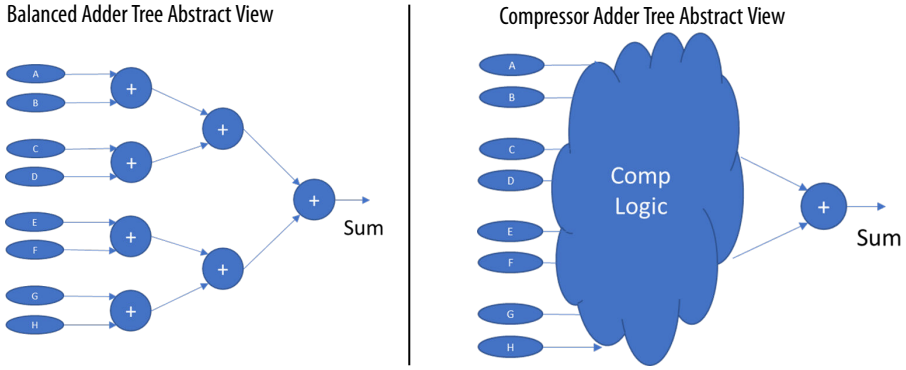
5.5.9.8. Change Adder Tree Styles

Structuring adder trees appropriately to match your targeted Intel FPGA device architecture and application can provide significant improvements in your design's efficiency and performance.

A good example of an application using a large adder tree is a finite impulse response (FIR) correlator. Using a pipelined binary or ternary adder tree appropriately can greatly improve the quality of your results for such applications.

Because ALMs can implement functions of up to six inputs, you can improve the performance of certain designs by using a compressor implementation for adder trees, rather than the default balanced binary tree implementation. The expected downside tradeoff of the compressor implementation is the use of more ALM logic resources. However, the overall logic depth is lower, and the final timing characteristics improve.

Figure 66. Balanced Binary Versus Compressor Style Adder Trees



For designs that may benefit, you can apply the **Use Compressor Implementation** (USE_COMPRESSOR_IMPLEMENTATION) global, entity, or instance assignment to specify whether the Compiler synthesizes adder trees as balanced binary trees, or as compressor style trees.

You can specify this assignment in the Assignment Editor, or with the following assignment in the `.qsf`.

```
set_instance_assignment -name USE_COMPRESSOR_IMPLEMENTATION ALWAYS -to <foo>
```

You can specify this assignment as either a global assignment, entity assignment, or instance assignment. You can alternatively use this assignment with `altera_attribute` to create instance assignments as well. For example:

```
(* altera_attribute = "-name USE_COMPRESSOR_IMPLEMENTATION ALWAYS" *) module
foo(a, b, c, o);
```

The following options are available for this assignment:

Table 34. Use Compressor Implementation Assignment Options

Option	Description
Always	The Compiler always synthesizes all adder trees with this assignment as compressor style trees. There is a limit of at least 2 non-constant operands before this triggers (otherwise synthesis implements a binary add or a pure-LUT implementation depending on size).
Never	The Compiler never synthesizes the assigned adder tree as a compressor. The Compiler synthesizes the adder as either a balanced binary tree, or if sufficiently small, in pure LUTs.
Auto	This setting currently behaves the same as the **Never** setting. The Compiler synthesizes the adder as either a balanced binary tree, or if sufficiently small, in pure LUTs. This setting never uses compressor style adder trees.

5.5.9.9. Duplicate Registers for Fan-Out Control

Often, timing failures can occur due to the influence of signals that are not directly involved in the failing transfers. This condition tends to manifest when off-critical nets, most commonly with a high fan-out, span a large distance and consequentially, warp the optimization of other paths around them.

Duplicating the sources of these types of globally-influential signals can help to disperse them across many hops, or even across many clock cycles, and focus more on local transfers.

For example, by duplicating a high fan-out signal in the form of a tree of registers, you can disperse the signal over several clock cycles. As the signal progresses down the tree, it progressively feeds more into local copies of the original registers, such that any individual register's destinations are well-localized and its influence on register optimization is minimal. The key to this optimization is to determine how to assign the original signal’s fan-outs among the duplicates. If any individual register requires driving a large distance, the benefit of the tree can be removed.

You can manually create a register tree and group the endpoints in the RTL by leveraging your system-level knowledge about how best to disperse the signal throughout your design, but it can be time consuming and have a widespread impact. For more information about manually creating a register tree, refer to Manual Register Duplication on page 122.

You can create register trees automatically in one of the following ways.

- Estimated Physical Proximity
- Hierarchical Proximity

Each method has its own methodology to determine the number of duplicates to create and how to assign the fan-outs between the duplicates.

5.5.9.9.1. Manual Register Duplication

Synthesis tools support options or attributes that specify the maximum fan-out of a register. When using Quartus Prime synthesis, you can set the **Maximum Fan-Out** logic option in the Assignment Editor to control the number of destinations for a node so that the fan-out count does not exceed a specified value. You can also use the `maxfan` attribute in your HDL code. The software duplicates the node as required to achieve the specified maximum fan-out.

Logic duplication using **Maximum Fan-Out** assignments normally increases resource utilization, and can potentially increase compilation time, depending on the placement and the total resource usage within the selected device.

The improvement in timing performance that results from **Maximum Fan-Out** assignments is design-specific. This is because when you use the **Maximum Fan-Out** assignment, the Fitter duplicates the source logic to limit the fan-out, but does not control the destinations that each of the duplicated sources drive. Therefore, it is possible for duplicated source logic to be driving logic located all around the device. To avoid this situation, you can use the **Manual Logic Duplication** logic option.

If you are using **Maximum Fan-Out** assignments, benchmark your design with and without these assignments to evaluate whether they give the expected improvement in timing performance. Use the assignments only when you get improved results.

You can manually duplicate registers in the Quartus Prime software regardless of the synthesis tool used. To duplicate a register, apply the **Manual Logic Duplication** logic option to the register with the Assignment Editor.

Note: Some Fitter optimizations may cause a small violation to the **Maximum Fan-Out** assignments to improve timing.

5.5.9.9.2. Automatic Register Duplication: Estimated Physical Proximity

The DUPLICATE_REGISTER assignment helps in leveraging estimated physical proximity information to guide the creation of duplicates and their fan-out assignments.

```
set_instance_assignment -name DUPLICATE_REGISTER -to <register_name>
<num_duplicates>
```

where,

- register_name is the register to duplicate. To create a register tree from a chain, create a unique assignment for each register in the chain. DUPLICATE_REGISTER assignments are processed in the appropriate order if they apply to registers that drive each other in a chain.
- num_duplicates is the number of duplicates of the register to create (including the original). If the original signal has M fan-out, the average fan-outs of the duplicates are M/N but any individual duplicate may have more or fewer, at the discretion of the algorithm.

The DUPLICATE_REGISTER assignment is processed during the Fitter stage. It is necessary to create the duplicates and assign fan-outs between the duplicates based on early estimates of physical proximity to maximize the amount of time spent optimizing the design post-duplication. However, this renders fine-grained assignment decisions imprecise. The DUPLICATE_REGISTER assignment is best used when the number of duplicates is small (under 100) and the groups created are coarse-grained enough to allow for flexibility during optimization after the duplicates are created.

The **Fitter Duplication Summary** panel of the Fit report details the DUPLICATE_REGISTER assignments picked up by Quartus Prime Pro Edition. It also summarizes any registered signal with greater than 1000 fan-outs, as they could be reasonable candidates for DUPLICATE_REGISTER assignments in future.

Important:

- Setting PHYSICAL_SYNTHESIS to OFF disables DUPLICATE_REGISTER.
- Unlike other physical synthesis optimizations, the DUPLICATE_REGISTER assignment does allow duplication of registers that feed asynchronous clears and registers having location assignments.
- The DUPLICATE_REGISTER assignment does not process registers that have any of the following conditions:
  - Registers drive global signals or clock signals.
  - Registers have timing assignments or exceptions applied to them.
  - Registers have a `preserve` attribute or a PRESERVE_REGISTER assignment.
  - Registers are marked as `don't touch`.
  - Registers drive or are driven by other partitions.

5.5.9.9.3. Automatic Register Duplication: Hierarchical Proximity

Leveraging design hierarchy information to guide the creation of duplicates and their fan-out assignments is enabled by the DUPLICATE_HIERARCHY_DEPTH assignment.

```
set_instance_assignment -name DUPLICATE_HIERARCHY_DEPTH -to <register_name>
<num_levels>
```

where,

- `register_name` is the last register in a chain that fans out to multiple hierarchies. To create a register tree, ensure that there are sufficient simple registers behind the node and those simple registers are automatically pulled into the tree.
- `num_levels` corresponds to the upper bound of the number of registers that exist in the chain to use for duplicating down the hierarchies.

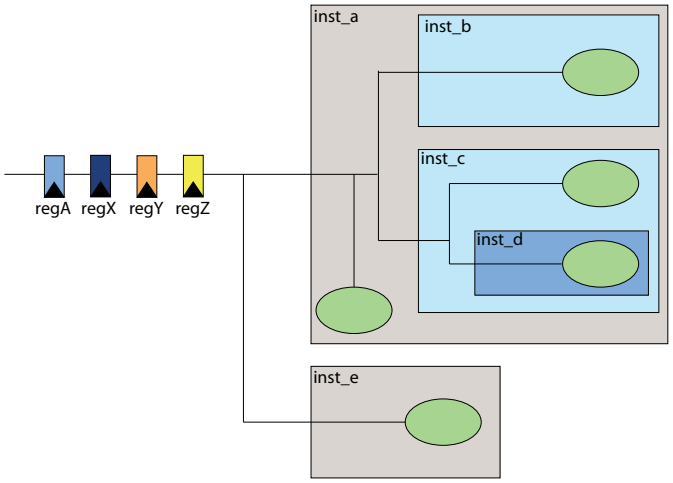
The DUPLICATE_HIERARCHY_DEPTH assignment is processed during the Synthesis stage. It is common for high-fanout signals to go through a pipeline of registers and drive into a sub-hierarchy of modules. For example, a system-wide reset can be propagated over several clock cycles and driven into many modules across the design. In several scenarios, it is useful to take advantage of the structure of this sub-hierarchy to infer the structure of the register tree to be created, such that endpoints within similar hierarchies are assigned the same copy of the signal, and branches in the design hierarchy dictates where to place branches in the register tree.

Important: The registers in the chain must satisfy all of the following conditions to be included in duplication:

- Registers must be fed only by another register.
- Registers must not be fed by a combinational logic.
- Registers must not be part of a synchronizer chain.
- Registers must not have any secondary signals.
- Registers must not have a `preserve` attribute or a PRESERVE_REGISTER assignment.
- All registers in the chain except the last one must have only one fan-out.

Consider the following example illustration of a netlist with a register chain and hierarchical organization of the endpoints it drives. The DUPLICATE_HIERARCHY_DEPTH assignment duplicates the pipeline registers across hierarchies, as shown in Registers Duplicated Across Hierarchies.

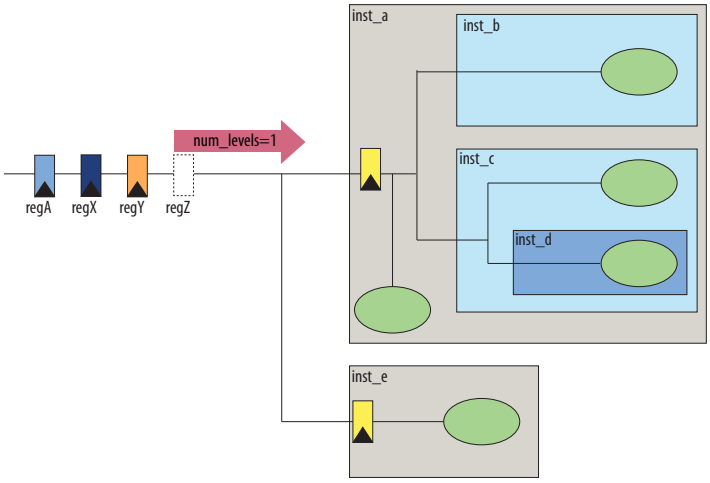
Figure 67. Original Diagram Showing Four Pipeline Registers Connected to Multiple Hierarchies



In this case, regZ is the appropriate assignment target as it is the endpoint in a chain of four registers. There is a maximum of three duplication candidates in this example (regZ, regY, and regX), so the assignment value can be anywhere between 1 and 3. regA is not pulled into the hierarchy to preserve the timing and optimization of paths that precede it. The DUPLICATE_HIERARCHY_DEPTH assignment is best used when a signal must be duplicated to more than 100 duplicates and the sub-hierarchy below the chain is deep and meaningful enough to guide the structure of the tree required.

Figure 68. Netlist After Duplicating regZ to Hierarchy Level One

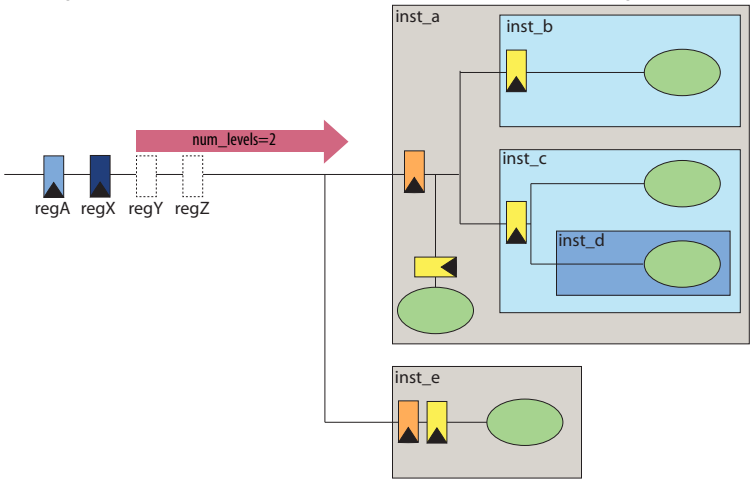
```
set_instance_assignment -name DUPLICATE_HIERARCHY_DEPTH -to regZ 1
```



When num_levels is set to 1, only regZ is pulled out of the chain and pushed down one hierarchy level into its fan-out tree.

Figure 69. Netlist After Duplicating regZ to Hierarchy Level Two

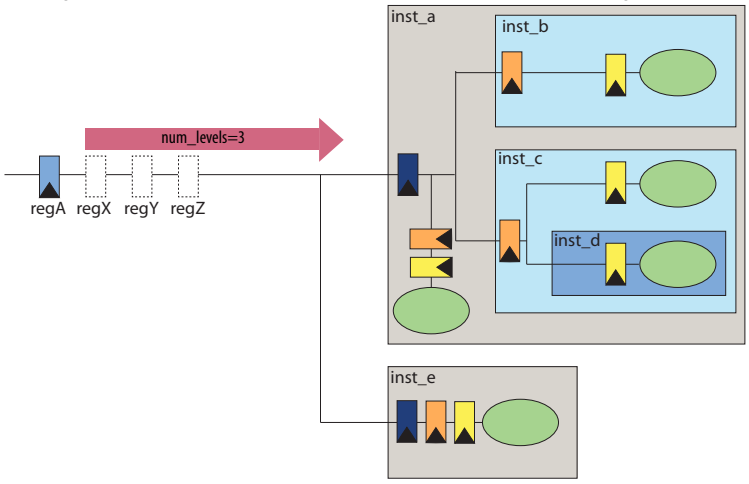
```
set_instance_assignment -name DUPLICATE_HIERARCHY_DEPTH -to regZ 2
```



When `num_levels` is set to 2, both `regY` and `regZ` are pulled out of the chain. `regZ` ends up at a maximum hierarchy depth two and `regY` ends up at hierarchy depth one.

Figure 70. Registers Duplicated Across Hierarchies

```
set_instance_assignment -name DUPLICATE_HIERARCHY_DEPTH -to regZ 3
```



When `num_levels` is set to 3, all three registers (`regZ`, `regY` and `regZ`) are pulled out of the chain and pushed to a maximum hierarchy depth of three, two, and one levels, respectively.

The **Hierarchical Tree Duplication Summary** panel in the Synthesis report provides information on the registers specified by the `DUPLICATE_HIERARCHY_DEPTH` assignment. It also includes a reason for the chain length that can be used as a starting point for further improvements with the assignment. The Synthesis report also provides a panel named **Hierarchical Tree Duplication Details**, which provides information about the individual registers in the chain that can be used to better understand the structure of the implemented duplicates.

5.5.9.10. Prevent Shift Register Inference

Turning off the inference of shift registers can increase performance. This setting forces the software to use logic cells to implement the shift register, instead of using the ALTSHIFT_TAPS IP core to implement the registers in memory block. If you implement shift registers in logic cells instead of memory, logic utilization increases.

5.5.9.11. Use Other Synthesis Options Available in Your Synthesis Tool

With your synthesis tool, experiment with the following options if they are available:

- Turn on register balancing or retiming
- Turn on register pipelining
- Turn off resource sharing

These options can increase performance, but typically increase the resource utilization of your design.

5.5.9.12. Fitter Seed

The Fitter seed affects the initial placement configuration of the design. Any change in the initial conditions changes the Fitter results; accordingly, each seed value results in a somewhat different fit. You can experiment with different seeds to attempt to obtain better fitting results and timing performance.

Changes in the design impact performance between compilations. This random variation is inherent in placement and routing algorithms—it is impossible to try all seeds and get the absolute best result.

Note: Any design change that directly or indirectly affects the Fitter has the same type of random effect as changing the seed value. This includes any change in source files, **Compiler Settings** or **Timing Analyzer Settings**. The same effect can appear if you use a different computer processor type or different operating system, because different systems can change the way floating point numbers are calculated in the Fitter.

If a change in optimization settings marginally affects the register-to-register timing or number of failing paths, you cannot always be certain that your change caused the improvement or degradation, or whether it is due to random effects in the Fitter. If your design is still changing, running a seed sweep (compiling your design with multiple seeds) determines whether the average result improved after an optimization change, and whether a setting that increases compilation time has benefits worth the increased time, such as with physical synthesis settings. The sweep also shows the amount of random variation to expect for your design.

If your design is finalized you can compile your design with different seeds to obtain one optimal result. However, if you subsequently make any changes to your design, you might need to perform seed sweep again.

Click **Assignments ➤ Compiler Settings** to control the initial placement with the seed. You can use the DSE II to perform a seed sweep easily.

To specify a Fitter seed use the following Tcl command :

```
set_global_assignment -name SEED <value>
```

5.5.9.13. Set Maximum Router Timing Optimization Level

To improve routability in designs where the router did not pick up the optimal routing lines, set the **Router Timing Optimization Level** to **Maximum**. This setting determines how aggressively the router tries to meet the timing requirements. Setting this option to **Maximum** can marginally increase design speed at the cost of increased compilation time. Setting this option to **Minimum** can reduce compilation time at the cost of marginally reduced design speed. The default value is **Normal**.

5.5.9.14. Register-to-Register Timing Analysis

Your design meets timing requirements when you do not have negative slack on any register-to-register path on any of the clock domains. When timing requirements are not met, a report on the failed paths can uncover more detail.

5.5.9.14.1. Tips for Analyzing Failing Paths

When you are analyzing failing paths, examine the reports and waveforms to determine if the correct constraints are being applied, and add timing exceptions as appropriate. A multicycle constraint relaxes setup or hold relationships by the specified number of clock cycles. A false path constraint specifies paths that can be ignored during timing analysis. Both constraints allow the Fitter to work harder on affected paths.

- Focus on improving the paths that show the worst slack. The Fitter works hardest on paths with the worst slack. If you fix these paths, the Fitter might be able to improve the other failing timing paths in the design.
- Check for nodes that appear in many failing paths. These nodes are at the top of the list in a timing report panel, along with their minimum slacks. Look for paths that have common source registers, destination registers, or common intermediate combinational nodes. In some cases, the registers are not identical, but are part of the same bus.
- In the timing analysis report panels, click the **From** or **To** column headings to sort the paths by source or destination registers. If you see common nodes, these nodes indicate areas of your design that might be improved through source code changes or Quartus Prime optimization settings. Constraining the placement for just one of the paths might decrease the timing performance for other paths by moving the common node further away in the device.

5.5.9.14.2. Tips for Analyzing Failing Clock Paths that Cross Clock Domains

When analyzing clock path failures:

- Check whether these paths cross two clock domains. In paths that cross two clock domains, the **From Clock** and **To Clock** in the timing analysis report are different.

Figure 71. Different Value in From Clock and To Clock Field

Setup Transfers

	From Clock	To Clock	RR Paths	FR Paths	RF Paths	FF Paths
1	clkin	clkin	21	0	0	0
2	clkin	clkout	false path	0	0	0
3	clkout	clkout	31	0	0	0

- Check if the design contains paths that involve a different clock in the middle of the path, even if the source and destination register clock are the same.
- Check whether failing paths between these clock domains need to be analyzed synchronously. Set failing paths that are not to be analyzed synchronously as false paths.
- When you run `report_timing` on a design, the report shows the launch clock and latch clock for each failing path. Check whether the relationship between the launch clock and latch clock is realistic and what you expect from your knowledge of the design. For example, the path can start at a rising edge and end at a falling edge, which reduces the setup relationship by one half clock cycle.
- Review the clock skew that appears in the Timing Report. A large skew may indicate a problem in the design, such as a gated clock, or a problem in the physical layout (for example, a clock using local routing instead of dedicated clock routing). When you have made sure the paths are analyzed synchronously and that there is no large skew on the path, and that the constraints are correct, you can analyze the data path. These steps help you fine tune your constraints for paths across clock domains to ensure you get an accurate timing report.
- Check if the PLL phase shift is reducing the setup requirement. You might adjust this by using PLL parameters and settings.
- Ignore paths that cross clock domains for logic protected with synchronization logic (for example, FIFOs or double-data synchronization registers), even if the clocks are related. Alternatively, specify the `set_clock_groups -exclusive` setting between unrelated clocks
- Set false path constraints on all unnecessary paths. Attempting to optimize unnecessary paths can prevent the Fitter from meeting the timing requirements on timing paths that are critical to the design.

Report CDC Viewer on page 93

5.5.9.14.3. Tips for Critical Path Analysis

When analyzing the failing paths in a design, it is helpful to understand the interactions around the critical paths.

To understand what may be pulling on a critical path, the following `report_timing` command can be useful.

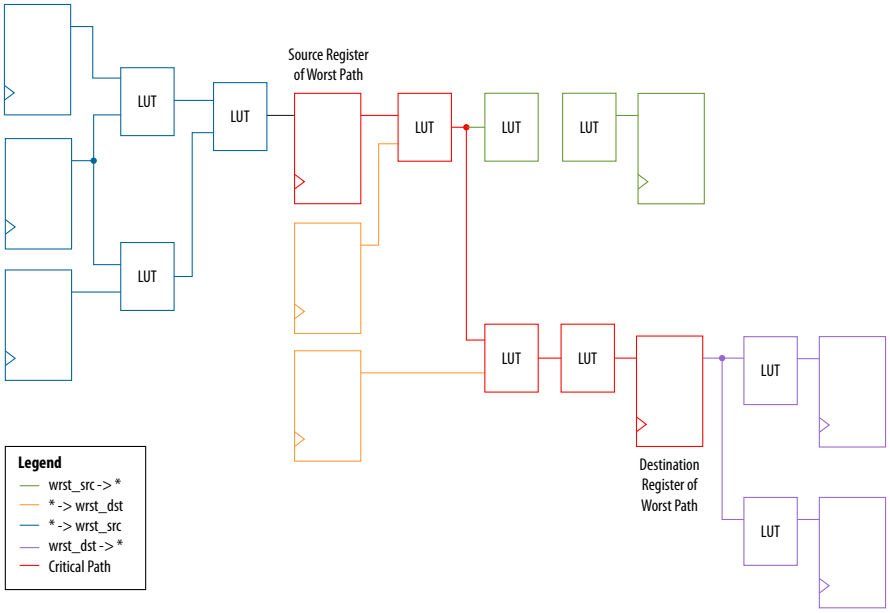
1. In the project directory, run the `report_timing` command to find the nodes in a critical path.
2. Copy the code below in a `.tcl` file, and replace the first two variable with the node names from the **From Node** and **To Node** columns of the worst path. The script analyzes the path between the worst source and destination registers.

```
set wrst_src <insert_source_of_worst_path_here>
set wrst_dst <insert_destination_of_worst_path_here>
report_timing -setup -npaths 50 -detail path_only -from $wrst_src \
-panel_name "Worst Path||wrst_src -> *"
report_timing -setup -npaths 50 -detail path_only -to $wrst_dst \
-panel_name "Worst Path||* -> wrst_dst"
report_timing -setup -npaths 50 -detail path_only -to $wrst_src \
-panel_name "Worst Path||* -> wrst_src"
report_timing -setup -npaths 50 -detail path_only -from $wrst_dst \
-panel_name "Worst Path||wrst_dst -> *"
```

3. From the **Script** menu, source the `.tcl` file.
4. In the resulting timing panel, locate timing failed paths (highlighted in red) in the Chip Planner, and view information such as distance between the nodes and large fan-outs.

   The figure shows a simplified example of what these reports analyzed.

Figure 72. Timing Report



The critical path of the design is in red. The relation between the `.tcl` script and the figure is:

- The first two lines show everything inside the two endpoints of the critical path that are pulling them in different directions.
  - The first `report_timing` command analyzes all paths the source is driving, shown in green.
  - The second `report_timing` command analyzes all paths going to the destination, including the critical path, shown in orange.
- The last two `report_timing` commands show everything outside of the endpoints pulling them in other directions.

If any of these neighboring paths have slacks near the critical path, the Fitter is balancing these paths with the critical path, trying to achieve the best slack.

Related Information

Review Timing Path Details on page 77

5.5.9.14.4. Tips for Creating a .tcl Script to Monitor Critical Paths Across Compiles

Many designs have the same critical paths show up after each compile. In other designs, critical paths bounce around between different hierarchies, changing with each compile.

This behavior happens in high speed designs where many register-to-register paths have very little slack. Different placements can then result in timing failures in the marginal paths.

1. In the project directory, create a script named `TQ_critical_paths.tcl`.
2. After compilation, review the critical paths and then write a generic `report_timing` command to capture those paths.

   For example, if several paths fail in a low-level hierarchy, add a command such as:

```
report_timing –setup –npaths 50 –detail path_only \
   –to “main_system: main_system_inst|app_cpu:cpu|*” \
   –panel_name “Critical Paths||s: * -> app_cpu”
```

3. If there is a specific path, such as a bit of a state-machine going to other `*count_sync*` registers, you can add a command similar to:

```
report_timing –setup –npaths 50 –detail path_only \
   –from “main_system: main_system_inst|egress_count_sm:egress_inst|update” \
   –to “*count_sync*” –panel_name “Critical Paths||s: egress_sm|update ->
count_sync”
```

4. Execute this script in the Timing Analyzer after every compilation, and add new `report_timing` commands as new critical paths appear.

   This helps you monitor paths that consistently fail and paths that are only marginal, so you can prioritize effectively

5.5.9.14.5. Global Routing Resources

Global routing resources are designed to distribute high fan-out, low-skew signals (such as clocks) without consuming regular routing resources. Depending on the device, these resources can span the entire chip or a smaller portion, such as a

quadrant. The Quartus Prime software attempts to assign signals to global routing resources automatically, but you might be able to make more suitable assignments manually.

For details about the number and types of global routing resources available, refer to the relevant device handbook.

Check the global signal utilization in your design to ensure that the appropriate signals have been placed on the global routing resources. In the Compilation Report, open the Fitter report and click **Resource Section**. Analyze the Global & Other Fast Signals and Non-Global High Fan-out Signals reports to determine whether any changes are required.

You might be able to reduce skew for high fan-out signals by placing them on global routing resources. Conversely, you can reduce the insertion delay of low fan-out signals by removing them from global routing resources. Doing so can improve clock enable timing and control signal recovery/removal timing, but increases clock skew. Use the **Global Signal** setting in the Assignment Editor to control global routing resources.

5.5.9.14.6. Register RAMS and DSPs

If your design includes long timing paths going to and from RAMs and DSPs, you must fully register the RAMs and DSPs.

RAM and DSP performance can vary, depending on the memory mode. A memory using read-during-write mode is slower than a memory that uses a different mode. Refer to your FPGA device documentation for hardware performance specifications. If the f_{MAX} is restricted due to mode, change to a different memory mode with a higher performance specification, if possible.

5.5.10. Metastability Analysis and Optimization Techniques

Metastability problems can occur when a signal is transferred between circuitry in unrelated or asynchronous clock domains, because the designer cannot guarantee that the signal meets its setup and hold time requirements. The mean time between failures (MTBF) is an estimate of the average time between instances when metastability could cause a design failure.

You can use the Quartus Prime software to analyze the average MTBF due to metastability when a design synchronizes asynchronous signals and to optimize the design to improve the MTBF. These metastability features are supported only for designs constrained with the Timing Analyzer, and for select device families.

Synchronization identification can affect retiming. Registers that the Compiler identifies as being part of a synchronizer are not retimed. The default chain length is 3, but in some cases, a synchronizer chain is not necessary and should not be inferred. Use the report_metastability command to identify synchronizer chains that you can reduce.

For example, consider a bus that uses a synchronized enable when crossing clock domains. If you pipeline such a bus, the pipeline stages can be considered as part of a synchronizer chain, and are not used to retime the paths. Setting the chain length to 1 for these paths allows the pipeline registers to be used for retiming.

5.6. Periphery to Core Register Placement and Routing Optimization

The Periphery to Core Register Placement and Routing Optimization (P2C) option specifies whether the Fitter performs targeted placement and routing optimization on direct connections between periphery logic and registers in the FPGA core. P2C is an optional pre-routing-aware placement optimization stage that enables you to more reliably achieve timing closure.

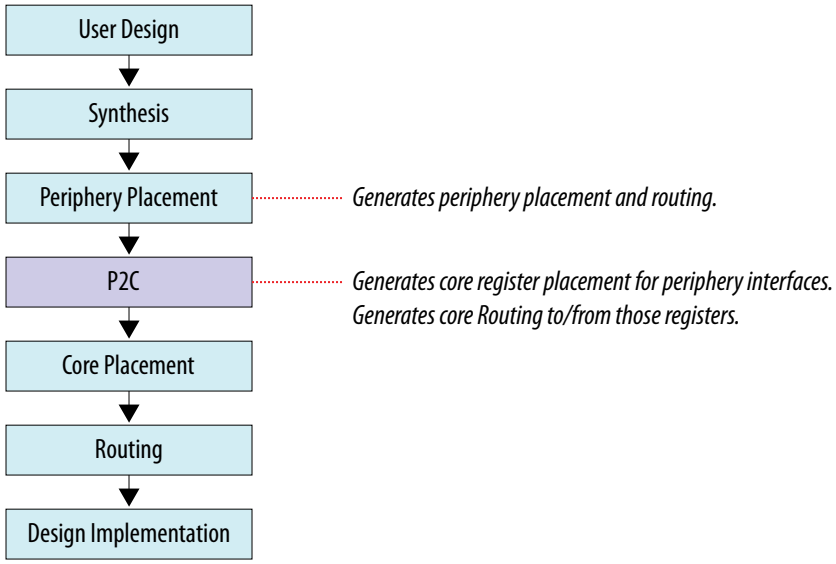
Note: The **Periphery to Core Register Placement and Routing Optimization** option applies in both directions, periphery to core and core to periphery.

Transfers between external interfaces (for example, high-speed I/O or serial interfaces) and the FPGA often require routing many connections with tight setup and hold timing requirements. When this option is turned on, the Fitter performs P2C placement and routing decisions before those for core placement and routing. This reserves the necessary resources to ensure that your design achieves its timing requirements and avoids routing congestion for transfers with external interfaces.

This option is available as a global assignment, or can be applied to specific instances within your design.

Figure 73. Periphery to Core Register Placement and Routing Optimization (P2C) Flow

P2C runs after periphery placement, and generates placement for core registers on corresponding P2C/C2P paths, and core routing to and from these core registers.



Setting Periphery to Core Optimizations in the Advanced Fitter Setting Dialog Box on page 134

Setting Periphery to Core Optimizations in the Assignment Editor on page 134

Viewing Periphery to Core Optimizations in the Fitter Report on page 135

5.6.1. Setting Periphery to Core Optimizations in the Advanced Fitter Setting Dialog Box

The **Periphery to Core Placement and Routing Optimization** setting specifies whether the Fitter optimizes targeted placement and routing on direct connections between periphery logic and registers in the FPGA core.

You can optionally perform periphery to core optimizations by instance with settings in the Assignment Editor.

1. In the Quartus Prime software, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**.
2. In the **Advanced Fitter Settings** dialog box, for the **Periphery to Core Placement and Routing Optimization** option, select one of the following options depending on how you want to direct periphery to core optimizations in your design:
   a. Select **Auto** to direct the software to automatically identify transfers with tight timing windows, place the core registers, and route all connections to or from the periphery.
   b. Select **On** to direct the software to globally optimize all transfers between the periphery and core registers, regardless of timing requirements.

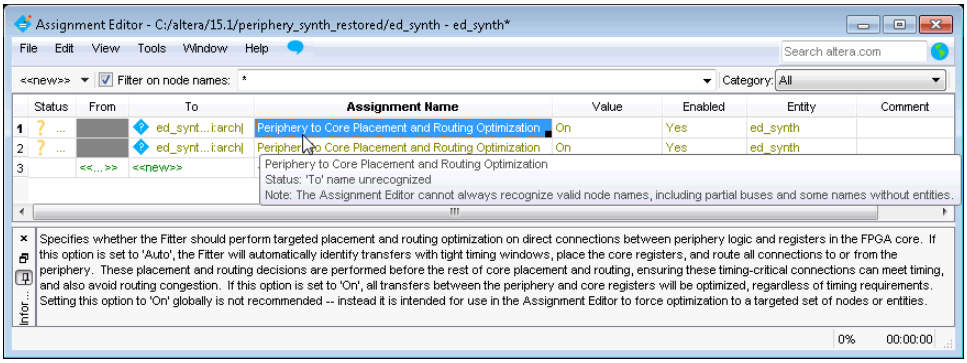
      Note: Setting this option to **On** in the **Advanced Fitter Settings** is not recommended. The intended use for this setting is in the Assignment Editor to force optimization for a targeted set of nodes or instance.
   c. Select **Off** to disable periphery to core path optimization in your design.

5.6.2. Setting Periphery to Core Optimizations in the Assignment Editor

When you turn on the **Periphery to Core Placement and Routing Optimization** (P2C/C2P) setting in the Assignment Editor, the Quartus Prime software performs periphery to core, or core to periphery optimizations on selected instances in your design.

You can optionally perform periphery to core optimizations by instance with settings in the **Advanced Fitter Settings** dialog box.

1. In the Quartus Prime software, click **Assignments ➤ Assignment Editor**.
2. For the selected path, double-click the **Assignment Name** column, and then click the **Periphery to core register placement and routing optimization** option in the drop-down list.
3. In the **To** column, choose either a periphery node or core register node on a P2C/C2P path you want to optimize. Leave the **From** column empty.
   For paths to appear in the Assignments Editor, you must first run Analysis & Synthesis on your design.



5.6.3. Viewing Periphery to Core Optimizations in the Fitter Report

The Quartus Prime software generates a periphery to core placement and routing optimization summary in the **Fitter (Place & Route)** report after compilation.

1. Compile your Quartus Prime project.
2. In the **Tasks** pane, select **Compilation**.
3. Under **Fitter (Place & Route)**, double-click **View Report**.
4. In the **Fitter** folder, expand the **Place Stage** folder.
5. Double-click **Periphery to Core Transfer Optimization Summary**.

Table 35. Fitter Report - Periphery to Core Transfer Optimization (P2C) Summary

From Path	To Path	Status
Node 1	Node 2	**Placed and Routed**—Core register is locked. Periphery to core/core to periphery routing is committed.
Node 3	Node 4	**Placed but not Routed**—Core register is locked. Routing is not committed. This occurs when P2C is not able to optimize all targeted paths within a single group, for example, the same delay/wire requirement, or the same control signals. Partial P2C routing commitments may cause unresolvable routing congestion.
Node 5	Node 6	**Not Optimized**—This occurs when P2C is set to **Auto** and the path is not optimized due to one of the following issues: a. The delay requirement is impossible to achieve. b. The minimum delay requirement (for hold timing) is too large. The P2C algorithm cannot efficiently handle cases when many wires need to be added to meet hold timing. c. P2C encountered unresolvable routing congestion for this particular path.

5.7. Scripting Support

You can run procedures and make settings described in this manual in a Tcl script. You can also run procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus Prime command-line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp
```

You can specify many of the options described in this section either in an instance, or at a global level, or both.

Use the following Tcl command to make a global assignment:

```
set_global_assignment -name <.qsf variable name> <value>
```

Use the following Tcl command to make an instance assignment:

```
set_instance_assignment -name <.qsf variable name> <value> -to <instance name>
```

Note: If the <*value*> field includes spaces (for example, 'Standard Fit'), you must enclose the value in straight double quotation marks.

5.8. Timing Closure and Optimization Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Revised *Aggregating and Comparing Compilation Results with Exploration Dashboard* and added links to *AN 1006: Multi-Project Analysis with Exploration Dashboard*. • Added link to *AN 917: Reset Design Techniques for Intel Hyperflex Architecture FPGAs* to *Synchronous Reset Design Strategies* topic. • Updated *Starting the Exploration Dashboard* for new GUI and added links to *AN 1006: Multi-Project Analysis with Exploration Dashboard*.
2023.10.02	23.3	• Updated version support information and introduction of the Exploration Dashboard GUI (`quartus_edw`) in *Aggregating and Comparing Compilation Results with Exploration Dashboard* topic. • Revised command syntax in *Base Exploration Dashboard Properties* topic. • Added new property names to *Project Handle Properties* topic. • Updated *Starting the Exploration Dashboard* for the Exploration Dashboard GUI (`quartus_edw`) and options.
2023.08.01	23.2	• Updated version support information in *Aggregating and Comparing Compilation Results with Exploration Dashboard* topic. • Corrected graphic size in *Use PLLs to Shift Clock Edges*.
2023.06.26	23.2	• Revised *Base Exploration Dashboard Properties* topic to describe user_data property.
2023.04.03	23.1	• Added new *Aggregating and Comparing Compilation Results with Exploration Dashboard* section. • Added new *Change Adder Tree Styles* topic describing new USE_COMPRESSOR_IMPLEMENTATION assignment. • Updated product family name to "Intel Agilex 7."
2022.01.07	21.4	• Clarified device applicability in *Spine Clock Limitations* topic. • Added Design Assistant information to *Review Timing Constraints* topic. • Added Design Assistant information to *Review Timing Constraints* topic. • Removed references to obsolete Advisors throughout. • Added Design Assistant information to *Optimize Source Code* topic. • Added Design Assistant information to *Improving Register-to-Register Timing* topic. • Added Design Assistant information to *Optimize Synthesis for Performance, Not Area* topic. • Added set_clock_groups -exclusive setting information to *Tips for Analyzing Failing Clock Paths that Cross Clock Domains* topic. • Added new *Register RAMS and DSPs* topic. • Revised *Metastability Analysis and Optimization Techniques* topic for synchronizers.
2021.10.04	21.3	• Updated name of Report Hierarchical Retiming Restrictions command and report to Report Retiming Restrictions.
2021.06.21	21.2	• Added note about variables that can cause differences in the compilation results between seed sweeps with DSE II.
2020.09.28	20.3	• Added "Back-Annotate Optimized Assignments" topic to describe new GUI support for back-annotation of pin, RAM, DSP, and clock assignments. • Added "Correct Design Assistant Rule Violations" topic. • Updated "Report Timing" topic for Extra Info tab data.

continued...

Document Version	Quartus Prime Version	Changes
		• Added new "Report Logic Depth," "Report Neighbor Paths, "Report Register Spread," "Report Route Net of Interest," "Report Hierarchical Retiming Restrictions," and "Report Pipelining Information," topics to "Review Details of Timing Paths" section. • Moved "Optimize Settings with Design Space Explorer II" to "Design Evaluation for Timing Closure" section and updated links to Help. • Retitled "Intel Stratix 10 Timing Closure Recommendations" topic to "Implement Fast Forward Timing Closure Recommendations".
2019.07.01	19.1	Added important notes to *Automatic Register Duplication: Estimated Physical Proximity* and *Automatic Register Duplication: Hierarchical Proximity* topics.
2019.04.01	19.1	• Added more information about register duplication methods in *Duplicate Logic for Fan-out Control* topic. • Moved content related to manual register duplication from *Duplicate Logic for Fan-out Control* topic to a newly created sub-topic *Manually Adding Duplicate Registers*. • Added *Automatic Register Duplication: Estimated Physical Proximity* and *Automatic Register Duplication: Hierarchical Proximity* as new sub-topics under *Duplicate Logic for Fan-out Control* to describe automatic register duplication process.
2018.11.12	18.1.0	• Updated "Placement Effort Multiplier" figure and text descriptions in "Adjust Placement Effort" topic. • Updated "Fitter Effort" figure and text descriptions in "Adjust Fitter Effort" topic. • Updated "Optimize Hold Timing Option" screenshot in "Wires Added for Hold" topic.
2018.09.24	18.1.0	• Removed duplicated topic: *Resource Utilization Optimization Techniques*. The topic is now in the *Area Optimization* chapter. • Removed reference to unsupported CARRY and CASCADE buffers from "Optimize IOC Register Placement for Timing Logic Option" topic.
2017.11.06	17.1.0	• Added support for Stratix 10 Hyper-Retiming, Fast Forward compilation, and Fast Forward Viewer. — Added topics: Critical Chains, Viewing Critical Chains, Intel Stratix 10 Timing Closure Recommendations, Retiming Limit Details Report, Using the Retiming Limit Details Report, Fast Forward Timing Closure Recommendations, Generating Fast Forward Timing Closure Recommendations, Implementing Fast Forward Recommendations. • Added topic about using partitions to achieve timing closure. • Moved Topic: Design Evaluation for Timing Closure after Initial Compilation: Optional Fitter Settings. • Removed statement about applying physical synthesis optimizations in a portion of a design. • Removed references to optimizing hold timing for selected paths. • Updated logic options about resource utilization optimization settings.
2017.05.08	17.0.0	• Added topic: *Critical Paths*. • Updated *Register-to-Register Timing* and renamed to *Register-to-Register Timing Analysis*. • Renamed topic: *Timing Analysis with the Timing Analyzer* to *Displaying Path Reports with the Timing Analyzer*. • Removed (LUT-Based Devices) remark from topic titles. • Renamed topic: *Optimizing Timing (LUT-Based Devices)* to *Timing Optimization*. • Renamed topic: *Debugging Timing Failures in the Timing Analyzer* to *Displaying Timing Closure Recommendations for Failing Paths*. • Renamed topic: *Improving Register-to-Register Timing Summary* to *Improving Register-to-Register Timing* .

continued...

Document Version	Quartus Prime Version	Changes
		• Removed topics: *Tips for Locating Multiple Paths to the Chip Planner*, *LogicLock Assignments* and *Hierarchy Assignments*, . • Removed reference to deprecated Fitter Effort Logic Option. • Removed information about Pin Advisor and Resource Optimization Advisor. • Removed figure: Clock Regions
2016.10.31	16.1.0	• Implemented Intel rebranding.
2016.05.02	16.0.0	• Removed information about deprecated physical synthesis options. • Added information about monitoring clustering difficulty.
2015.11.02	15.1.0	• Added: *Periphery to Core Register Placement and Routing Optimization*. • Changed instances of *Quartus II* to *Quartus Prime*.
2014.12.15	14.1.0	• Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Synthesis Optimizations to Compiler Settings. • Updated DSE II content.
June 2014	14.0.0	• Dita conversion. • Removed content about obsolete devices that are no longer supported in QII software v14.0: Arria GX, Arria II, Cyclone III, Stratix II, Stratix III. • Replaced Megafunction content with IP core content.
November 2013	13.1.0	• Added Design Evaluation for Timing Closure section. • Removed Optimizing Timing (Macrocell-Based CPLDs) section. • Updated Optimize Multi-Corner Timing and Fitter Aggressive Routability Optimization. • Updated Timing Analysis with the Timing Analyzer to show how to access the **Report All Summaries** command. • Updated Ignored Timing Constraints to include a help link to *Fitter Summary Reports* with the **Ignored Assignment Report** information.
May 2013	13.0.0	• Renamed chapter title from Area and Timing Optimization to Timing Closure and Optimization. • Removed design and area/resources optimization information. • Added the following sections: Fitter Aggressive Routability Optimization. Tips for Analyzing Paths from/to the Source and Destination of Critical Path. Tips for Locating Multiple Paths to the Chip Planner. Tips for Creating a .tcl Script to Monitor Critical Paths Across Compiles.
November 2012	12.1.0	• Updated "Initial Compilation: Optional Fitter Settings" on page 13–2, "I/O Assignments" on page 13–2, "Initial Compilation: Optional Fitter Settings" on page 13–2, "Resource Utilization" on page 13–9, "Routing" on page 13–21, and "Resolving Resource Utilization Problems" on page 13–43.
June 2012	12.0.0	• Updated "Optimize Multi-Corner Timing" on page 13–6, "Resource Utilization" on page 13–10, "Timing Analysis with the Timing Analyzer" on page 13–12, "Using the Resource Optimization Advisor" on page 13–15, "Increase Placement Effort Multiplier" on page 13–22, "Increase Router Effort Multiplier" on page 13–22 and "Debugging Timing Failures in the Timing Analyzer" on page 13–24. • Minor text edits throughout the chapter.

continued...

Document Version	Quartus Prime Version	Changes
November 2011	11.1.0	• Updated the "Timing Requirement Settings", "Standard Fit", "Fast Fit", "Optimize Multi-Corner Timing", "Timing Analysis with the Timing Analyzer", "Debugging Timing Failures in the Timing Analyzer", "LogicLock Assignments", "Tips for Analyzing Failing Clock Paths that Cross Clock Domains", "Flatten the Hierarchy During Synthesis", "Fast Input, Output, and Output Enable Registers", and "Hierarchy Assignments" sections • Updated Table 13–6 • Added the "Spine Clock Limitations" section • Removed the Change State Machine Encoding section from page 19 • Removed Figure 13-5 • Minor text edits throughout the chapter
May 2011	11.0.0	• Reorganized sections in "Initial Compilation: Optional Fitter Settings" section • Added new information to "Resource Utilization" section • Added new information to "Duplicate Logic for Fan-Out Control" section • Added links to Help • Additional edits and updates throughout chapter
December 2010	10.1.0	• Added links to Help • Updated device support • Added "Debugging Timing Failures in the Timing Analyzer" section • Removed Classic Timing Analyzer references • Other updates throughout chapter
August 2010	10.0.1	Corrected link
July 2010	10.0.0	• Moved Compilation Time Optimization Techniques section to new *Reducing Compilation Time* chapter • Removed references to Timing Closure Floorplan • Moved Smart Compilation Setting and Early Timing Estimation sections to new *Reducing Compilation Time* chapter • Added Other Optimization Resources section • Removed outdated information • Changed references to DSE chapter to Help links • Linked to Help where appropriate • Removed Referenced Documents section

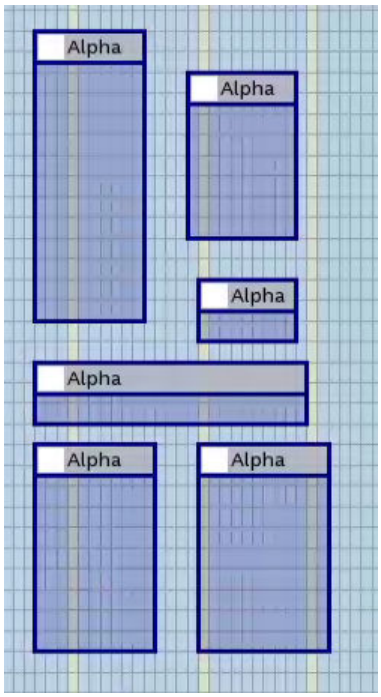
6. Analyzing and Optimizing the Design Floorplan

Determining the layout (placement) of your design elements into physical resources on the FPGA device is known as floorplanning. Floorplanning is a critical design step that helps to ensure that the Compiler places important design logic in the most effective locations for optimum performance and rapid timing closure.

By default, the Compiler determines the best location for logic placement based on your design characteristics and project settings and constraints. You can use the Quartus Prime Chip Planner to visualize the available device resources, and then use a variety of constraints to implement specific placement for important logic, and to group blocks together within specific device regions.

For example, you can define a Logic Lock placement constraint to assign design logic to any arbitrary region of physical resources on the target device that you define. When you assign nodes or entities to the Logic Lock region, the Compiler always places that logic inside the region during fitting. You can define the Logic Lock region's size and location.

Figure 74. Logic Lock Regions in Chip Planner Floorplan



After compilation, you can back-annotate (copy) the Compiler's resource assignments to preserve that same implementation in subsequent compilations. Assignment back-annotation can simplify timing closure by allowing you to lock down placement of your optimized results.

Related Information

Back-Annotate Optimized Assignments, Quartus Prime Pro Edition User Guide: Getting Started

6.1. Location Assignment Optimization Guidelines

Refer to the following optimization guidelines for assigning locations to specific registers and combinational nodes.

Guideline: Assigning Logic to Specific Locations

As part of design optimization, you may want to assign logic in your design to specific locations in the target device floorplan. You may want to make this type of assignment to preserve a good placement result, or to replicate a result in future compiles. In most cases, design partitions are the best way to preserve placement. For more information, refer to *Creating a Design Partition* in *Quartus Prime Pro Edition User Guide: Design Compilation*

Guideline: Assigning the Location of One or Two Registers

Sometimes, you may want to assign the location of one or two registers or combinational nodes. In cases where the amount of logic is extremely small, a design partition is not usually practical. If you want to restrict placement to an area of the floorplan, you can use a Logic Lock region placement constraint. For more information, refer to Defining Logic Lock Placement Constraints.

Guideline: Assigning a Register to a Specific Location in an ALM

If you want to assign a register to a specific location in an ALM, you must know the specific location you want to assign. The specific location includes the X and Y coordinates of the LAB that contains the ALM, as well as the sub-location of the register in the ALM in the LAB. The easiest way to find this information during design optimization is to start from a compiled version of the design, and review a timing path report in the Timing Analyzer. Use the string in the Location column as the value for a location assignment.

For example, to assign the `LOOP[42].my_div|r[6]` register to the location shown in Example Compilation Results, use the following QSF statement:

```
set_location_assignment -to LOOP[42].my_div|r[6] FF_X117_Y26_N49
```

Figure 75. Example Compilation Results

Data Arrival Path

	Total	Incr	RF	Type	Fanout	Location	Element Type	Element
17	8.103	0.317	RR	IC	1	FF_X117_Y26_N49	ALM Register	LOOP[42].my_div|r[6]|d
18	8.103	0.000	RR	CELL	1	FF_X117_Y26_N49	ALM Register	LOOP[42].my_div|r[6]

Guideline: Making Assignments to Compiler-Modified Nodes

If you make location assignments to registers that the Compiler modifies or optimizes during compilation, is unlikely that the Compiler will honor the assignment in subsequent compiles. Compiler-modified or optimized registers include a suffix that begins with a tilde character (~). If the Compiler modifies a register during compilation, the suffix is likely to change on subsequent compiles as you change other parts of the circuit. When the suffix changes, the name associated with the assignment also changes, so the Compiler does not honor the assignment.

Guideline: Assigning Combinational Logic to Specific Locations

Generally it is not worth assigning combinational logic to specific locations. Combinational logic names are more likely to change in subtle ways from one compile to another. When the names change, any location assignments are ignored if the names don't match.

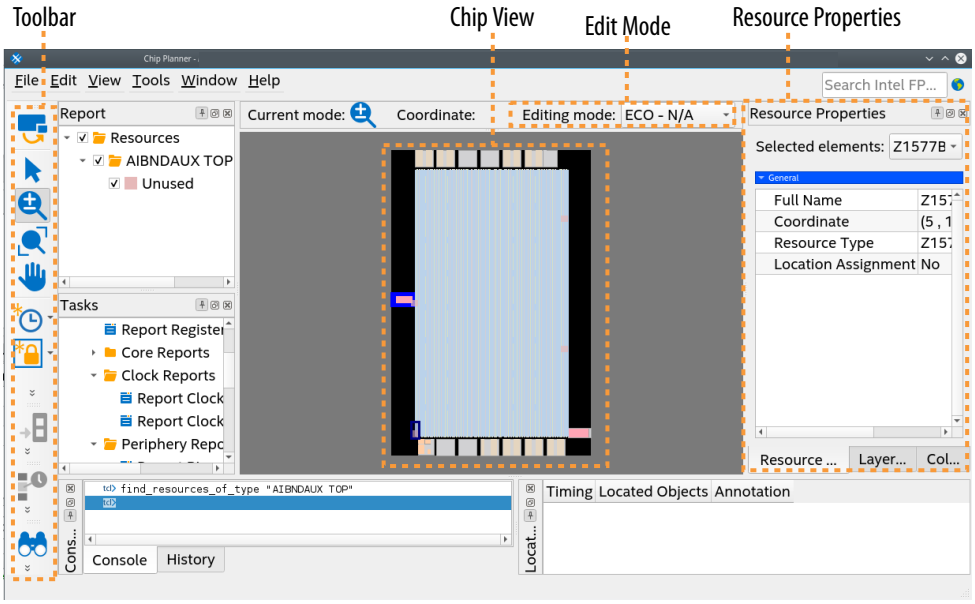
6.2. Design Floorplan Analysis in Chip Planner

The Chip Planner simplifies floorplanning by allowing you to view and constrain design logic within a visual display of the FPGA chip resources. You can use the Chip Planner to view and modify the logic placement, connections, and routing paths after running the Fitter. You can also make assignment changes, such as creating and deleting Logic Lock, clock region, and resource assignments.

Figure 76. The Chip Planner

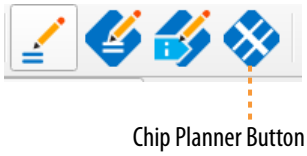


6.2.1. Starting the Chip Planner

To start the Chip Planner, select **Tools ➤ Chip Planner**. You can also start the Chip Planner by using any of the following methods:

- Click the Chip Planner button on the Quartus Prime software toolbar.

Figure 77. Chip Planner Button on Toolbar

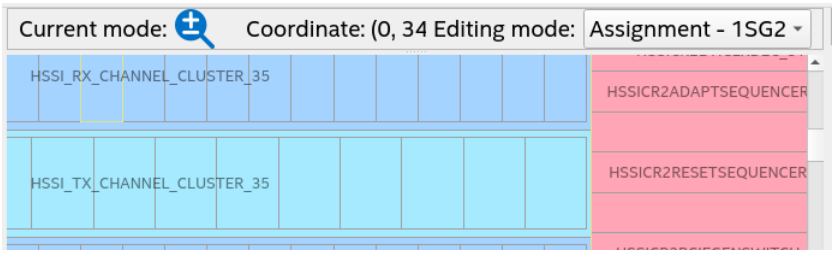


- In the following tools, right-click any chip resource and select **Locate ➤ Locate in Chip Planner**:
  - Compilation Report
  - **Logic Lock Regions Window**
  - Technology Map Viewer
  - **Project Navigator** window
  - Node Finder
  - Simulation Report
  - Report Timing panel of the Timing Analyzer

6.2.2. Chip Planner GUI

The Chip Planner GUI helps you to visualize and modify the use of device resources for your design. As you zoom in, the level of abstraction decreases, revealing more details about your design.

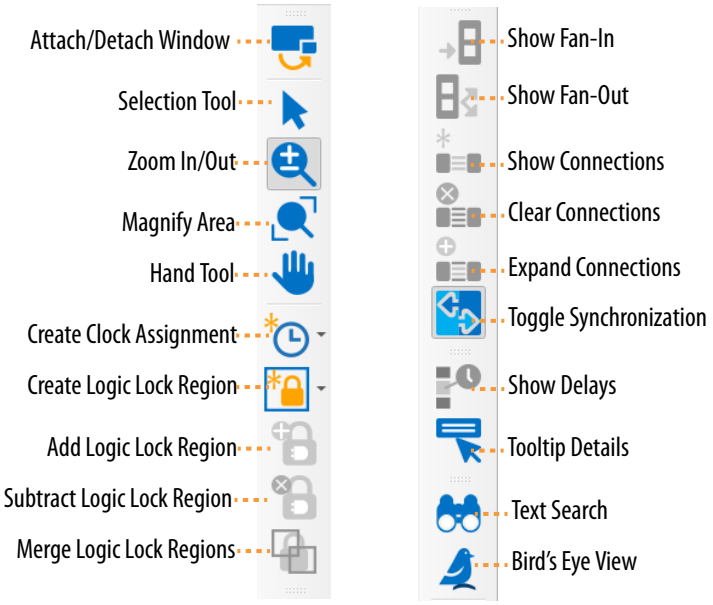
Figure 78. Zoom to View Device Resource Details in Chip Planner



Chip Planner Toolbar

The Chip Planner toolbar provides access to the main Chip Planner functions for visualizing and modifying device resources. Alternatively, you can access the same Chip Planner commands from the Chip Planner **View** menu.

Figure 79. Chip Planner Toolbar

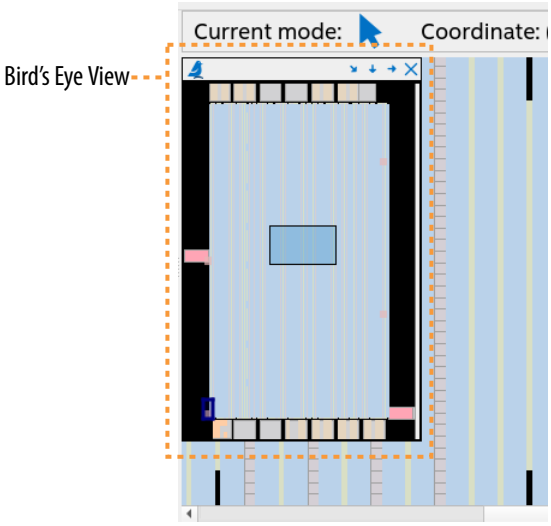


Chip Planner Floorplan Views

The Chip Planner includes multiple views to shows various levels of detail for the targeted Intel FPGA device. You can toggle between these different views when you require more or less detail. As you zoom in to the chip, the level of abstraction decreases, revealing more details about the resources that your design targets.

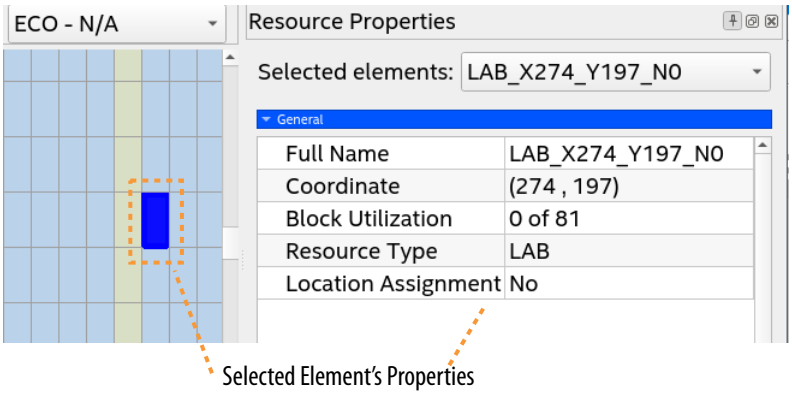
Click the **Bird's Eye View** button to instantly display a summary high-level chip view, on top of your current Chip Planner view. Use this Bird's Eye view to show your current selection within the larger chip, and to navigate quickly between areas of interest.

Figure 80. Bird's Eye View



The Bird's Eye View is particularly useful when the parts of your design that you want to view are at opposite ends of the chip, allowing you to quickly navigate between resource elements without losing the current frame of reference.

Figure 81. Selected Element Properties



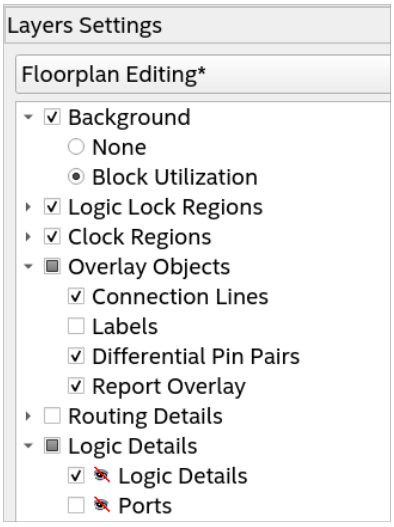
When you select any element in the Chip Planner, the **Properties** window displays the detailed properties of the objects (such as atoms, paths, Logic Lock regions, or routing elements). To display the **Properties** window, right-click the object and select **View ➤ Properties**.

Layers Settings Pane

clicking **View ➤ Layers Settings** to customize which device structures the Chip Planner displays.

You can select the **Basic**, **Detailed**, or **Floorplan Editing** settings that are preconfigured for specific planning tasks, or specify your own layer settings.

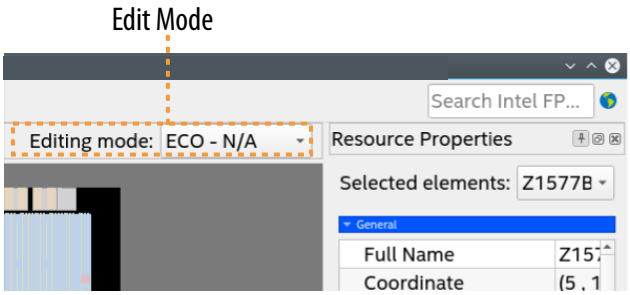
Figure 82. Layer Settings Control Display of Device Resources



Editing Mode

The Chip Planner has two editing modes.

Figure 83. Editing Mode Selection



- **Assignment**—editing mode allows you to make assignment changes that are implemented the next time you run the Fitter.
- **ECO**—editing mode allows you to make post-compilation changes, commonly referred to as engineering change orders (ECOs), without running a full compilation.

Locate History

The **Locate History** window records all searches you perform using the **Locate in Chip Planner** command, allowing you to quickly rerun common searches.

6.2.3. Viewing Design Elements in Chip Planner

The Chip Planner allows you to locate and report details on various elements of your design, such as viewing available clock networks, routing congestion, I/O banks, design partitions, and high-speed serial interfaces in the floorplan.

The following section describes how to view various design elements in the Chip Planner.

6.2.3.1. Viewing Architecture-Specific Design Information in Chip Planner

The Chip Planner allows you to view architecture-specific information related to your design. By enabling the options in the **Layers Settings** pane and **Properties** tab, you can view:

- **Device routing resources used by your design**—view how blocks are connected, as well as the signal routing that connects the blocks.
- **LE configuration**—view logic element (LE) configuration in your design. For example, you can view which LE inputs are used; whether the LE utilizes the register, the look-up table (LUT), or both; as well as the signal flow through the LE.
- **ALM configuration**—view ALM configuration in your design. For example, you can view which ALM inputs are used; whether the ALM utilizes the registers, the upper LUT, the lower LUT, or all of them. You can also view the signal flow through the ALM.

- **I/O configuration**—view device I/O resource usage. For example, you can view which components of the I/O resources are used, whether the delay chain settings are enabled, which I/O standards are set, and the signal flow through the I/O.
- **PLL configuration**—View phase-locked loop (PLL) configuration in your design. For example, you can view which control signals of the PLL are used with the settings for your PLL.
- **Timing**—view the delay between the inputs and outputs of FPGA elements. For example, you can analyze the timing of the DATAB input to the COMBOUT output.

6.2.3.2. Viewing Available Clock Networks in Chip Planner

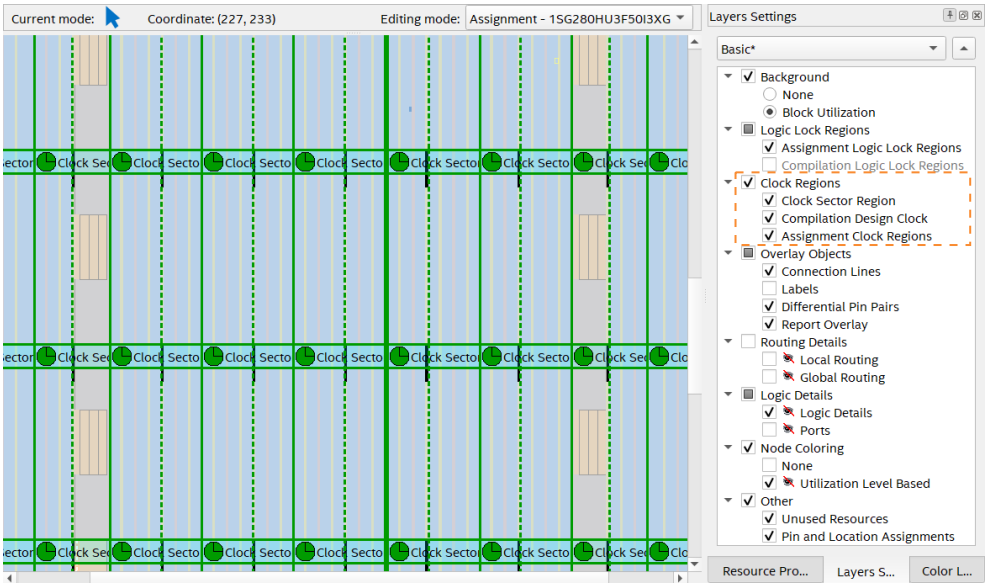
When you enable a clock region layer in the **Layers Settings** pane, you display the areas of the chip that are driven by global and regional clock networks. When the selected device does not contain a given clock region, the option for that category is unavailable in the dialog box.

Depending on the clock layers that you activate in the **Layers Settings** pane, the Chip Planner displays regional and global clock regions in the device, and the connectivity between clock regions, pins, and PLLs.

Note: The Stratix 10 and Agilex 7 device clocking architecture does not include regional clocks nor spine clocks.

Clock regions appear as rectangular overlay boxes with labels indicating the clock type and index. Select a clock network region by clicking the clock region. The clock-shaped icon at the top-left corner indicates that the region represents a clock network region.

Figure 84. Clock Regions



Spine/sector clock regions have a dotted vertical line in the middle. This dotted line indicates where two columns of row clocks meet in a sector clock.

To change the color in which the Chip Planner displays clock regions, select **Tools ➤ Options ➤ Colors ➤ Clock Regions**.

Related Information

Spine Clock Limitations on page 116

6.2.3.3. Viewing Clock Sector Utilization in Chip Planner

The Chip Planner provides a visual representation of a design's clock sector utilization.

To generate the report in the Chip Planner:

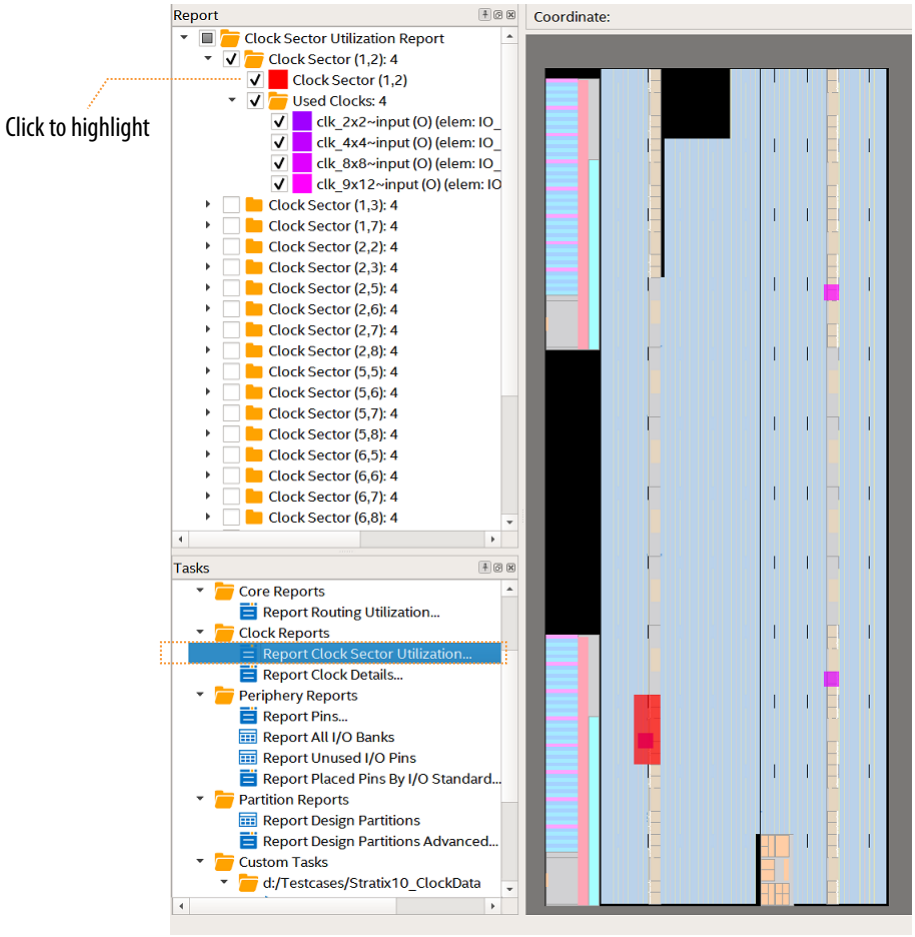
1. In the **Tasks** pane, double-click **Report Clock Sector Utilization** to open the **Report Clock Sector Utilization** dialog box.
2. If you want the report to include the source nodes, turn on **Report source nodes**.
   The equivalent TCL command appears at the bottom of the Dialog Box.
3. Click **OK**.

   The report output shows the most used clock sectors.

The **Report** pane displays a list of clock sectors, with colors according to utilization. The clock sector with the highest utilization appears in red, and the sector with least utilization appears in blue.

You can turn on or off the sector visibility from the **Report** pane. You can also highlight nodes, if applicable.

Figure 85. Clock Sector Utilization Report



6.2.3.4. Viewing Routing Congestion in Chip Planner

The **Report Routing Utilization** task allows you to determine the percentage of routing resources in use following a compilation. This feature can identify zones with lack of routing resources, helping you to make design changes to meet routing congestion design requirements.

To view the routing congestion in the Chip Planner:

1. In the **Tasks** pane, double-click the **Report Routing Utilization** command to launch the **Report Routing Utilization** dialog box.
2. Click **Preview** in the **Report Routing Utilization** dialog box to preview the default congestion display.
3. Change the **Routing Utilization Type** to display congestion for specific resources.
   The default display uses dark blue for 0% congestion (blue indicates zero utilization) and red for 100%. You can adjust the slider for **Threshold percentage** to change the congestion threshold level.

The congestion map helps you determine whether you can modify the floorplan, or modify the RTL to reduce routing congestion. Consider:

- The routing congestion map uses the color and shading of logic resources to indicate relative resource utilization; darker shading represents a greater utilization of routing resources. Areas where routing utilization exceeds the threshold value that you specify in the **Report Routing Utilization** dialog box appear in red.
- To identify a lack of routing resources, you must investigate each routing interconnect type separately by selecting each interconnect type in turn in the **Routing Utilization Settings** dialog box.
- The Compiler's messages contain information about average and peak interconnect usage. Peak interconnect usage over 75%, or average interconnect usage over 60%, can indicate difficulties fitting your design. Similarly, peak interconnect usage over 90%, or average interconnect usage over 75%, show increased chances of not getting a valid fit.

Related Information

Viewing Routing Resources on page 162

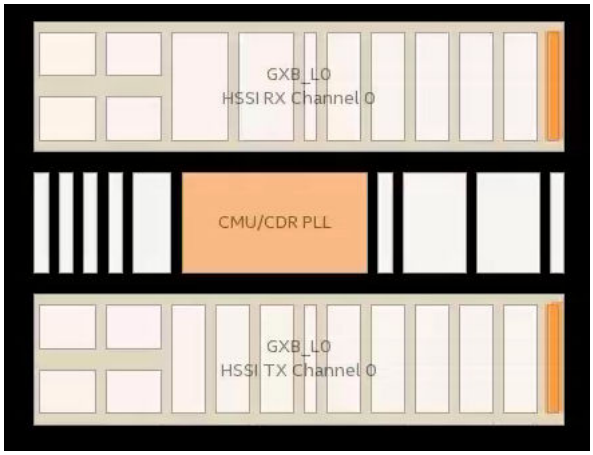
6.2.3.5. Viewing I/O Banks in Chip Planner

To view the I/O bank map of the device in the Chip Planner, double-click **Report All I/O Banks** in the **Tasks** pane.

6.2.3.6. Viewing High-Speed Serial Interfaces (HSSI) in Chip Planner

The Chip Planner displays a detailed block view of the receiver and transmitter channels of the high-speed serial interfaces. To display the HSSI block view, double-click **Report HSSI Block Connectivity** in the **Tasks** pane.

Figure 86. Arria 10 HSSI Channel Blocks



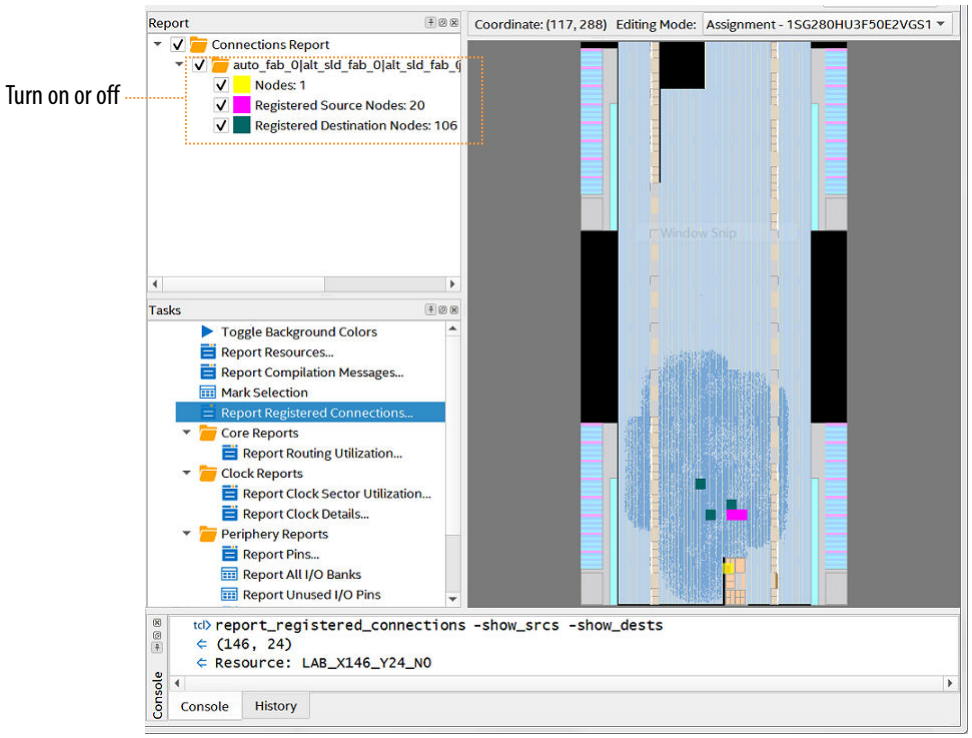
6.2.3.7. Viewing Source and Destination Nodes in Chip Planner

The Chip Planner allows you to view the registered fan-in or fan-outs of nodes in compiled designs with the **Report Registered Connections** task. This report is different from the **Generate Fanin/Fanout connections** report in that the source and destination nodes appear without connection lines, which may obscure the view.

1. In the Chip Planner, select one or more nodes.
2. In the **Task** pane, double-click **Report Registered Connections**.
3. Select the options from the dialog box, and click **OK**.

The **Reports** pane displays the registered source and destination nodes. Turn on or off to switch visibility in the graphic view.

Figure 87. Report Registered Connections



Related Information

Viewing Fan-In and Fan-Out in Chip Planner on page 153

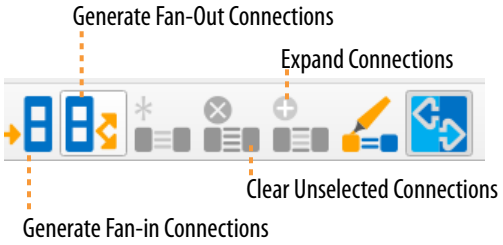
6.2.3.8. Viewing Fan-In and Fan-Out in Chip Planner

Displays the atoms that fan-in to or fan-out from a resource, including connectivity lines.

To display the fan-in or fan-out connections from a resource you selected,

1. In the Chip Planner toolbar, click the **Generate Fan-In Connections** button or the **Generate Fan-Out Connections** button.

Figure 88. Chip Planner Toolbar Buttons



2. To remove other connections that appear on the Chip Planner view, click the **Clear Unselected Connections** button.

You can also perform this actions from the Chip Planner **View** menu.

Related Information

Viewing Source and Destination Nodes in Chip Planner on page 152

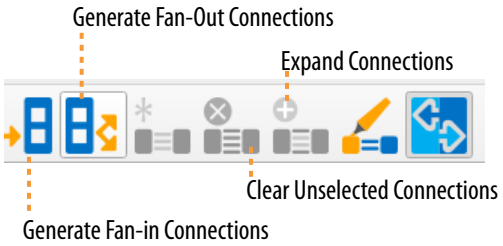
6.2.3.9. Viewing Immediate Fan-In and Fan-Out in Chip Planner

Displays the immediate fan-in or fan-out connection for the selected atom.

For example, when you view the immediate fan-in for a logic resource, you see the routing resource that drives the logic resource. You can generate immediate fan-ins and fan-outs for all logic resources and routing resources.

- To display the immediate fan-in or fan-out connections, click **View ➤ Generate Immediate Fan-In Connections** or **View ➤ Generate Immediate Fan-Out Connections**.
- To remove the connections displayed, use the **Clear Unselected Connections** button in the Chip Planner toolbar.

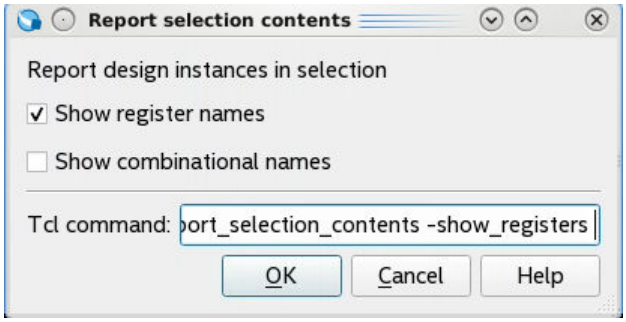
Figure 89. Chip Planner Toolbar Buttons



6.2.3.10. Viewing the Selected Contents in Chip Planner

You can view a detailed report of the contents of any area that you select in the Chip Planner. When you view the contents of a selected area, Chip Planner generates a hierarchical, color coded list of the design elements in the selection. This functionality allows you to quickly determine where the Compiler places specific modules of the design.

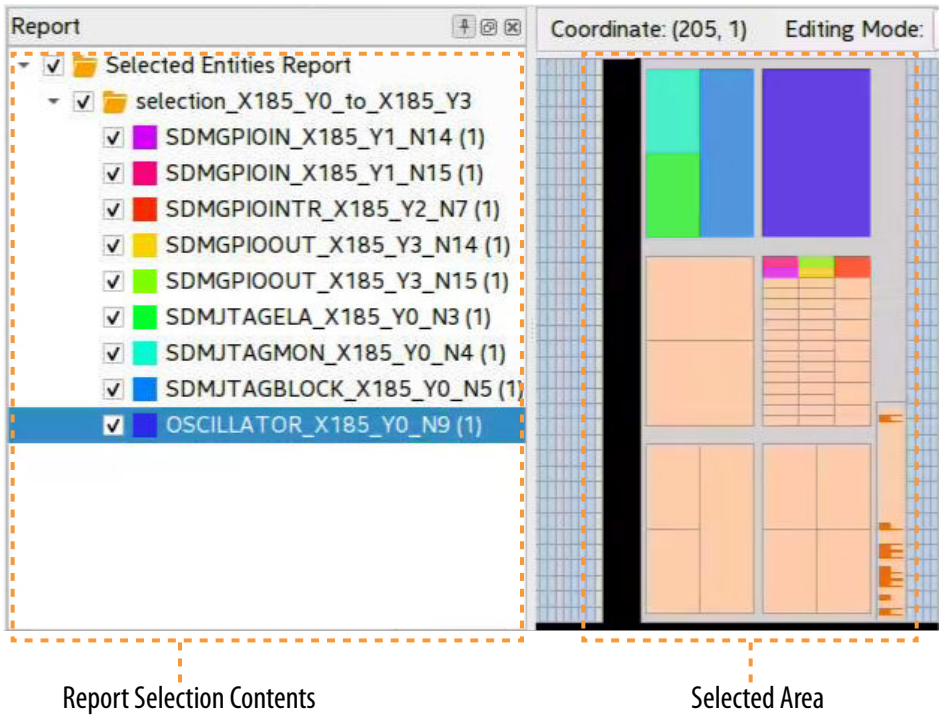
Figure 90. Report Selection Contents Dialog Box



Follow these steps to view selected contents in the Chip Planner:

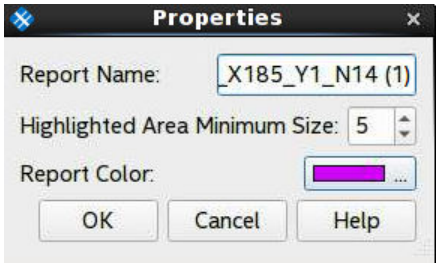
1. In the **Tasks** pane, double-click **Report Selection Contents**. The **Report Selection Contents** dialog box appears.
2. Under **Report design instances in selection**, turn on or off **Show registers names** and **Show combinational names** to display names of those type in the report.
3. Click **OK**. The report generates and displays the list of selected elements in the **Reports** pane.

Figure 91. Viewing Selected Contents



4. To customize the color coding of report folders, right-click any report, and then click **Properties**. You can customize the **Report Name**, **Report Color**, and the **Highlighted Area Minimum Size** for the report.

Figure 92. Selected Entities Report Properties



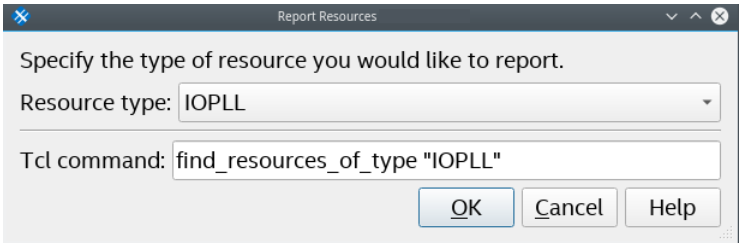
6.2.3.11. Viewing the Location and Utilization of Device Resources in Chip Planner

Chip Planner can generate reports about the different types of device resources located in the in Chip Planner view, including the resource location and utilization.

To view the location and utilization of a device resource in Chip Planner:

1. On the Chip Planner **Tasks** pane, click **Report Resources**. The **Report Resources** dialog box appears.

Figure 93. Report Resources Dialog Box



2. In **Resource Type**, select the device resource type that you want to locate.
3. Click **OK**. The report generates and displays the list of selected resources in the **Reports** pane.
4. In the Reports pane, right-click a resource type to Zoom to Report or view the Properties of the resource in the Resources report.

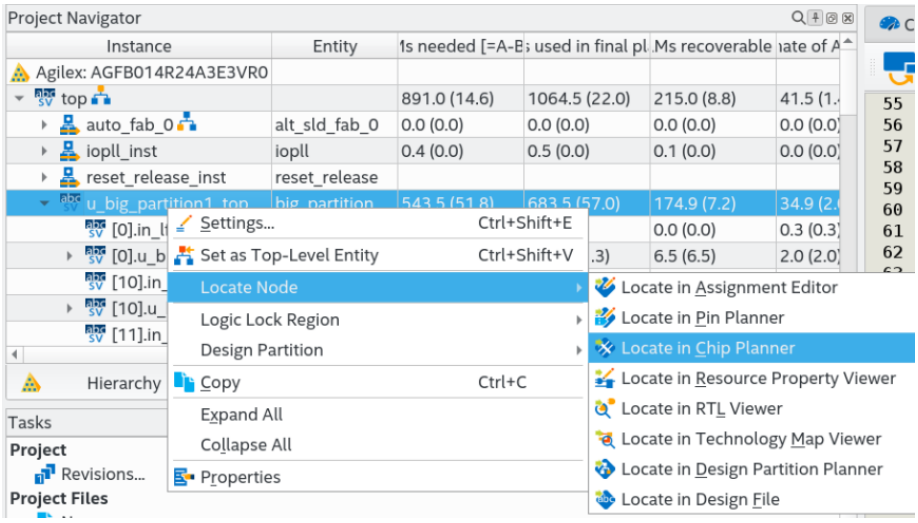
6.2.3.12. Viewing Module Placement by Cross-Probing to Chip Planner

You can use cross-probing to determine the location of a design module on the device in Chip Planner.

To view the placement of a module with cross-probing following place and route:

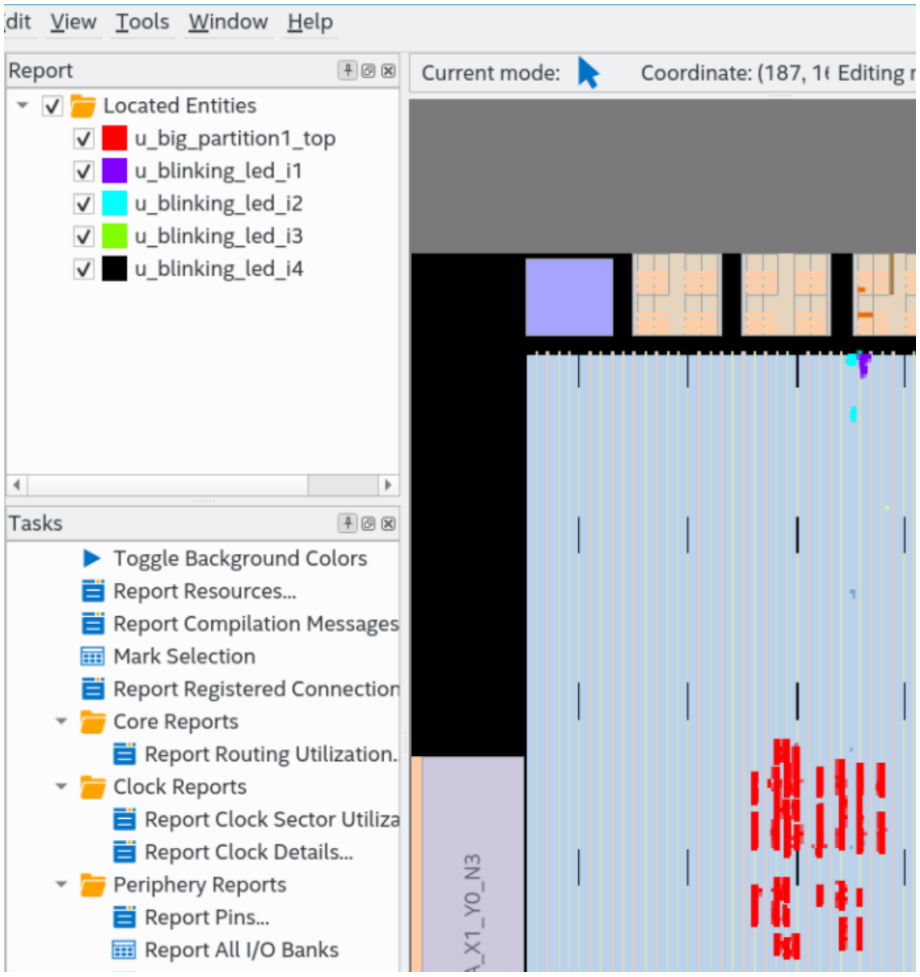
1. On the Project Navigator Hierarchy tab, right-click on a module name and click **Locate in Chip Planner**.

Figure 94. Locate in Chip Planner Command from Project Navigator



2. In the Reports pane, view the list of **Located Entities** color-coded and separated by module.

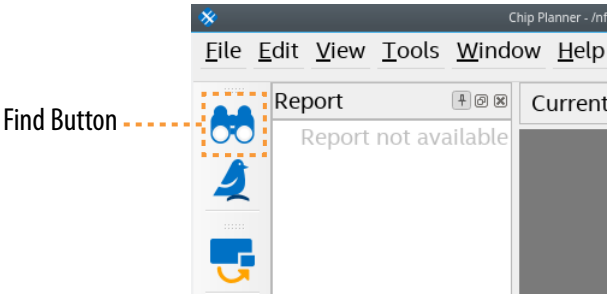
Figure 95. Located Entities in Reports Pane



6.2.4. Finding Design Elements in the Chip Planner

Use the **Find** tab to locate any design atom, port, location, or routing element by name within the Chip Planner view. The **Find** tab located in Chip Planner, you can view more information about the element on the **Properties** tab.

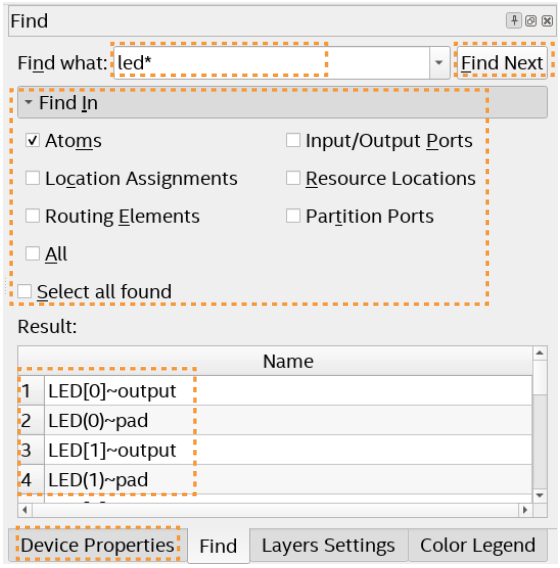
Figure 96. Click the Find Button to Search Chip Planner



To use the **Find** tab to locate design elements in Chip Planner:

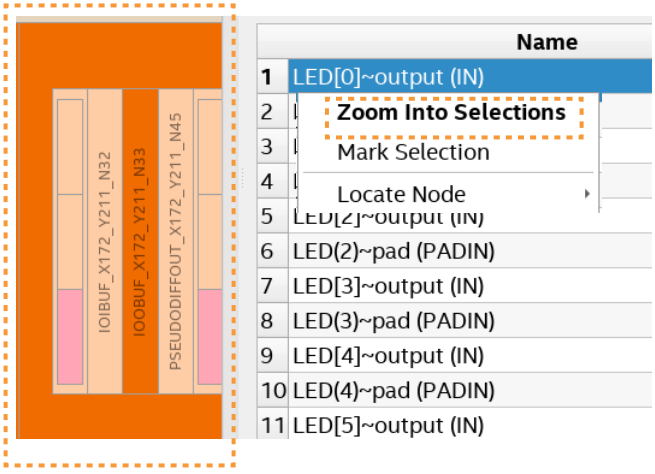
1. In Chip Planner, click the **Find** button. The **Find** tab opens.
2. In **Find what**, enter the design element name(s) (and any wildcard characters) to find in Chip Planner.
3. Under **Find In**, enable or disable the types of design elements to include in the search, as Find Options (Chip Planner Search) on page 160 describes.

Figure 97. Find Options and Controls



4. To begin the search, click **Find Next**. The search results display in the **Results** list.
5. To view details about any item in the **Results** list, click the **Properties** tab.
6. To locate found elements in Chip Planner, right-click the design element in the **Results** list and click **Zoom Into Selections**. Chip Planner zooms into the selected elements.

Figure 98. Zoom Into Selections from Search Results



6.2.4.1. Find Options (Chip Planner Search)

You can enable or disable the following **Find In** options to narrow or expand the search for design elements in Chip Planner:

Table 40. Find In Options

Option	Description
Atoms	Finds all matching atom names in the design within Chip Planner.
Location Assignments	Finds all matching location assignments in the design within Chip Planner.
Routing Elements	Find all matching routing element names in the design within Chip Planner.
All	Find all matching elements of all supported types within Chip Planner.
Input/Output Ports	Find all matching input and output port names in the design within Chip Planner.
Resource Locations	Find all matching routing element names in the design within Chip Planner.
Partition Ports	Find all matching partition port names in the design within Chip Planner.
Select all found	Automatically selects all found elements following search.

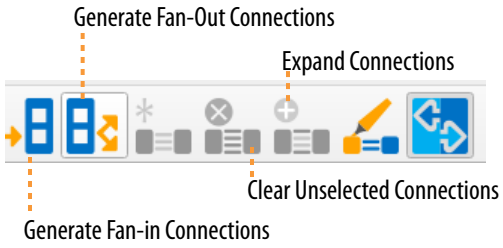
6.2.5. Exploring Paths in the Chip Planner

Use the Chip Planner to explore paths between logic elements. The following examples use the Chip Planner to traverse paths from the Timing Analysis report.

6.2.5.1. Analyzing Connections for a Path

To determine the elements forming a selected path or connection in the Chip Planner, click the **Expand Connections** button in the Chip Planner toolbar.

Figure 99. Chip Planner Toolbar Buttons



6.2.5.2. Locate Path from the Timing Analysis Report to the Chip Planner

To locate a path from the Timing Analysis report to the Chip Planner, perform the following steps:

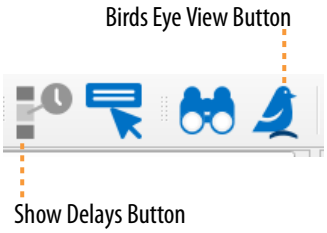
1. Select the path you want to locate in the Timing Analysis report.
2. Right-click the path and point to **Locate Path ➤ Locate in Chip Planner**. The path appears in the **Locate History** window of the Chip Planer.

Figure 100. Path List in the Locate History Window

6.2.5.3. Show Delays

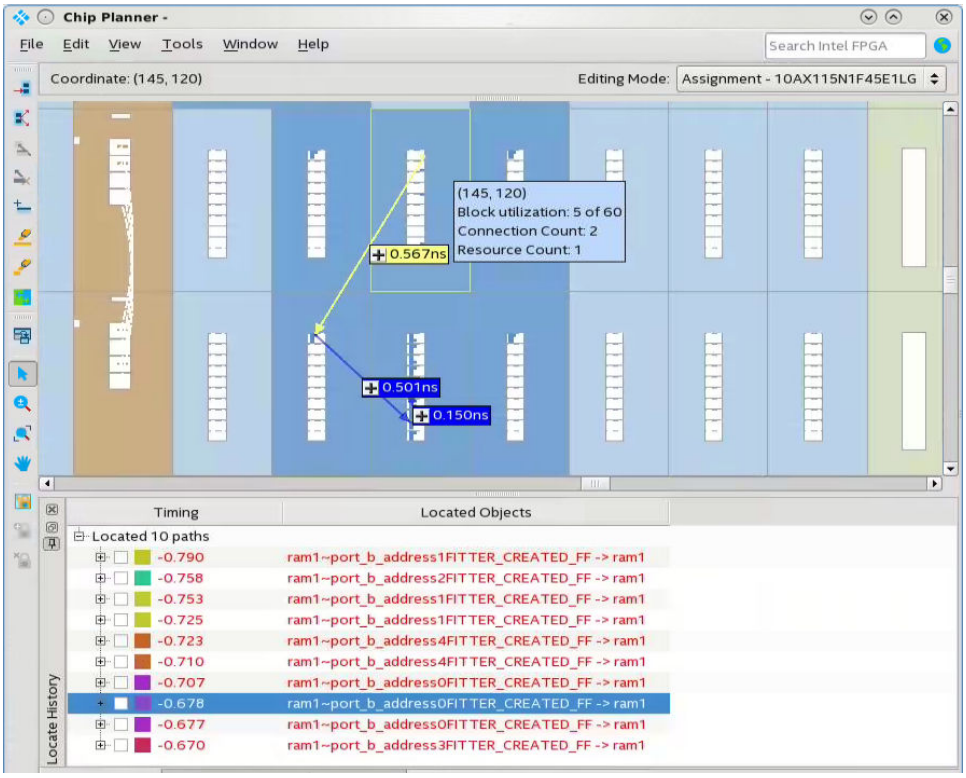
With the **Show Delays** feature, you can view timing delays for paths appearing in Timing Analyzer reports. To access this feature, click **View ➤ Show Delays** in the main menu. Alternatively click the **Show Delays** button in the Chip Planner toolbar. To see the partial delays on the selected path, click the "+" sign next to the path delay displayed in the **Locate History** window.

Figure 101. Show Delays Button on Chip Planner Toolbar



For example, you can view the delay between two logic resources or between a logic resource and a routing resource.

Figure 102. Show Delays Associated in a Timing Analyzer Path



6.2.5.4. Viewing Routing Resources

With the Chip Planner and the **Locate History** window, you can view the routing resources that a path or connection uses. You can also select and display the Arrival Data path and the Arrival Clock path.

In the **Locate History** window, right-click a path and select **Show Physical Routing** to display the physical path. To adjust the display, right-click and select **Zoom to Selection**.

Figure 103. Show Physical Routing

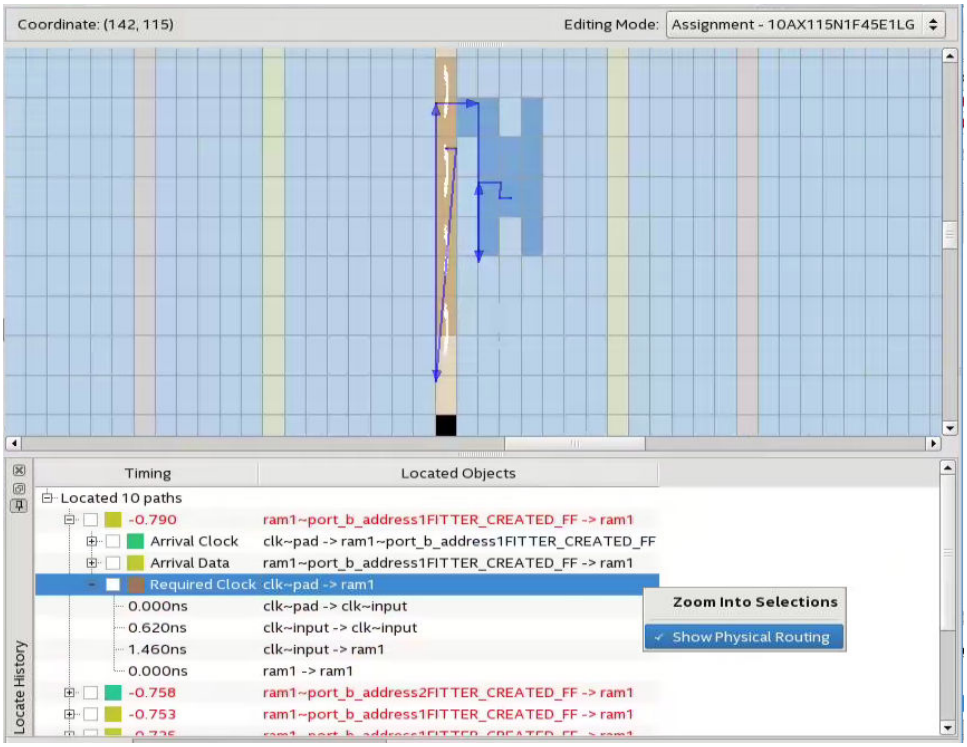


Figure 104. Highlight Routing

To see the rows and columns where the Fitter routed the path, right-click a path and select **Highlight Routing**.

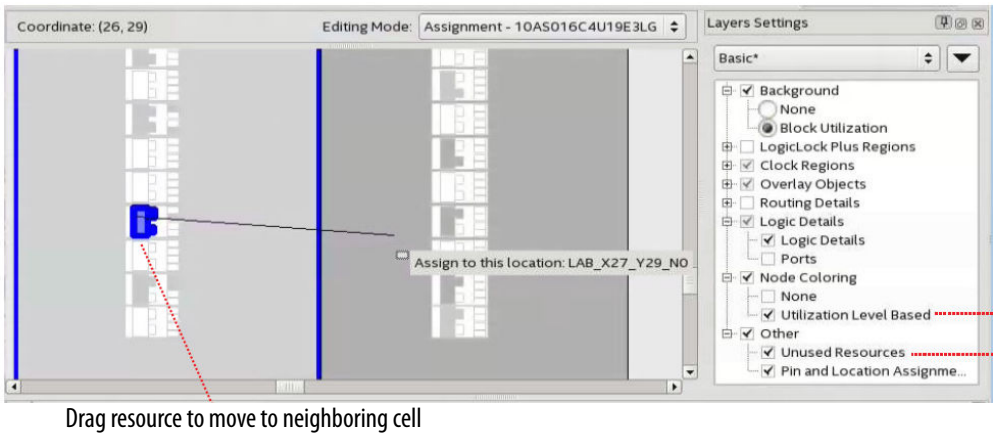
Viewing Routing Congestion in Chip Planner on page 151

6.2.6. Viewing Assignments in the Chip Planner

You can view location assignments in the Chip Planner by selecting the appropriate layer, or any custom preset that displays block utilization in the **Layers Settings** pane. The Chip Planner displays assigned resources in a predefined color (gray, by default).

Figure 105. Viewing Assignments in the Chip Planner

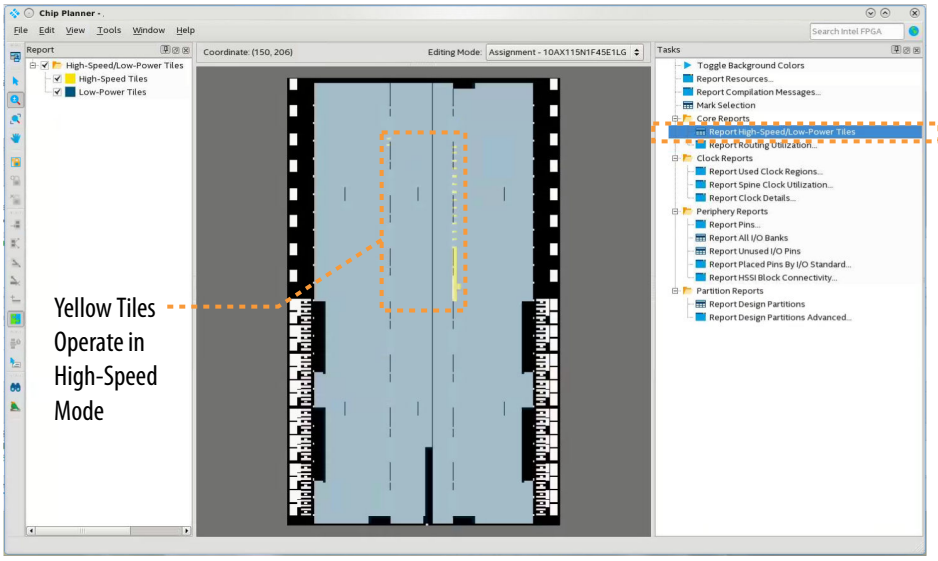


To create or move an assignment, or to make node and pin location assignments to Logic Lock regions, drag the selected resource to a new location. The Fitter applies the assignments that you create during the next place-and-route operation.

6.2.7. Viewing High-Speed and Low-Power Tiles in the Chip Planner

Some Intel devices have ALMs that can operate in either high-speed mode or low-power mode. The power mode is set during the fitting process in the Quartus Prime software. These ALMs are grouped together to form larger blocks, called "tiles".

Figure 106. High-Speed and Low Power Tiles in an Arria 10 Device



To view a power map, double-click **Tasks ➤ Core Reports ➤ Report High-Speed/ Low-Power Tiles** after running the Fitter. The Chip Planner displays low-power and high-speed tiles in contrasting colors; yellow tiles operate in a high-speed mode, while blue tiles operate in a low-power mode.

6.2.8. Viewing Design Partition Placement

With the **Report Design Partitions** command, you can view the physical placement of design partitions using the same color map as the Design Partition Planner.

The **Report Design Partitions Advanced** command opens the **Report Design Partitions Advanced** dialog box that allows you to select a partition and generate a report of the pins belonging to the partition. It highlights the selected partition's boundary ports and pins in the Chip Planner, and optionally reports the routing utilization and routing element details.

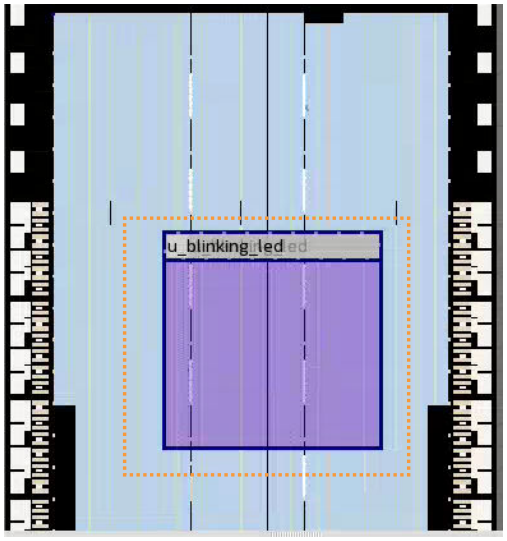
6.3. Defining Logic Lock Placement Constraints

A Logic Lock region is a powerful type of logic placement and routing constraint. You can define any arbitrary region of physical resources on the target device as a Logic Lock region, and then assign design nodes and other properties to the region. When you constrain design nodes to a Logic Lock region, the Fitter always places those nodes within the region resulting in more predictable results with each design iteration.

Your floorplan can contain multiple Logic Lock regions, depending on your design characteristics. You can also define a routing region as part of a Logic Lock region. The routing region specifies the routing area constraint.

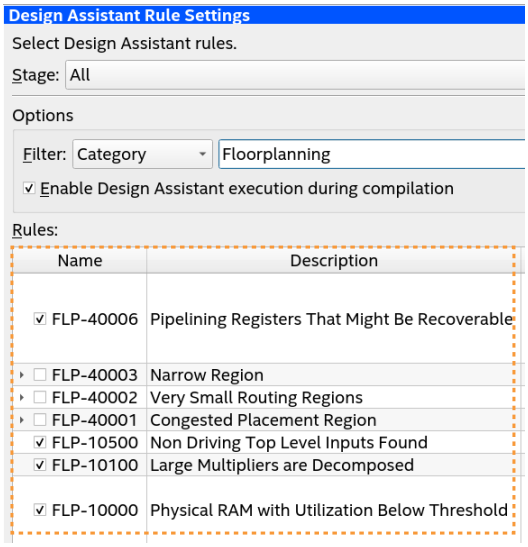
The Chip Planner makes it easy to visualize and constrain device resources within a device floorplan. You can draw or specify the dimensions of a Logic Lock region in the floorplan using the Logic Lock Regions window. After running synthesis or fitting, you can then assign design nodes as members of the region to implement the constraint.

Figure 107. u_blinking_led Logic Lock Region Defined in Chip Planner



To detect and resolve any potential problems with Logic Lock regions in your project, click **Report DRC** to run the Design Assistant to check for the FLP rule category. FLP Design Assistant rules detect possible issues with floorplanning and Logic Lock regions.

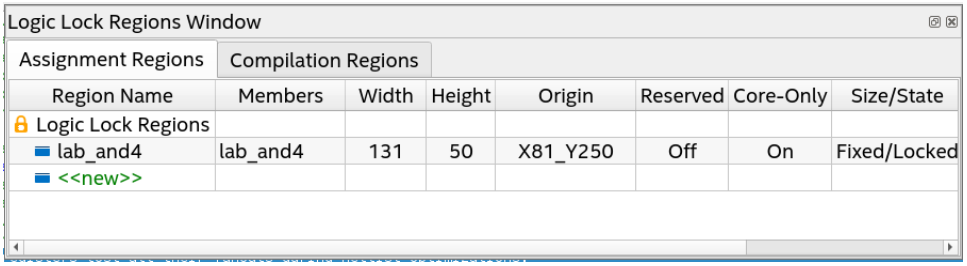
Figure 108. Floorplanning (FLP) Design Assistant Rules



6.3.1. The Logic Lock Regions Window

Use the Logic Lock Regions window GUI to view, define, and modify the attributes of Logic Lock regions in your project.

Figure 109. Logic Lock Regions Window



The Logic Lock Regions window organizes the constraints into the following two tabs:

Table 41. Logic Lock Regions Window Tabs

Logic Lock Regions Window Tab	Description
Assignment Regions	Displays the properties of all Logic Lock regions that you define in the current project (saved in the `.qsf`). Modify Logic Lock region properties in this tab.
Compilation Regions	Displays the properties of any Logic Lock region contained in a `.qdb` file in the project. Tab is read-only because you must edit imported Logic Lock region properties in the original project.

Open the Logic Lock Regions window by clicking:

- **Assignments ➤ Logic Lock Window**.
- **View ➤ Logic Lock Window** in the Chip Planner.
- Right-click **Logic Lock Region ➤ Logic Lock Regions Window** in Project Navigator.

You can customize the appearance of Logic Lock Regions window by dragging the columns to change their order and showing or hiding optional columns by right-clicking any column.

6.3.2. Defining Logic Lock Regions

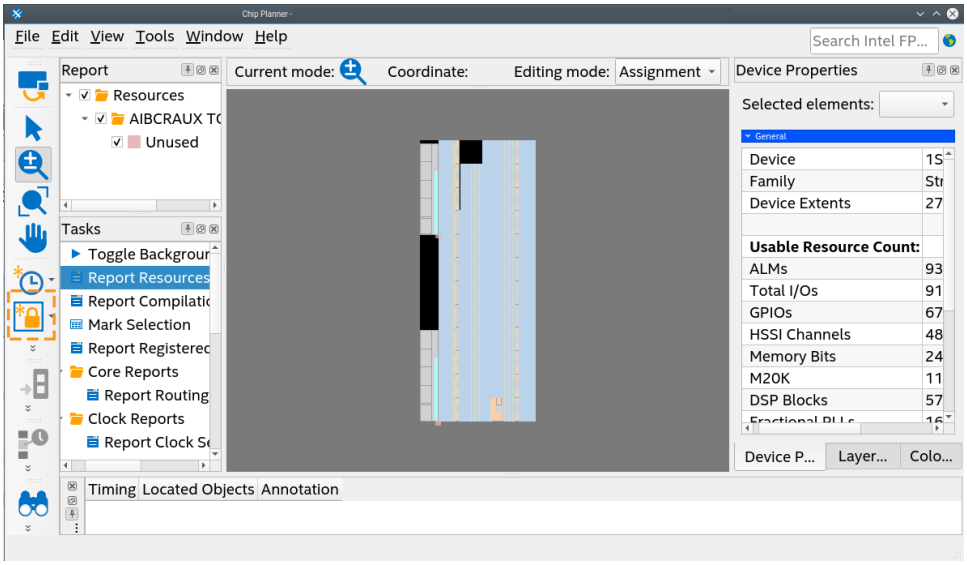
The Quartus Prime provides multiple entry points in the GUI to create and modify Logic Lock constraints as appropriate in your workflow.

- Before Analysis & Elaboration—you can use the Logic Lock Regions window and the Chip Planner to visualize the chip and define empty regions without member nodes.
- After Analysis & Elaboration or Fitter—you can assign member nodes, and even define a Logic Lock region from a selected design entity.

You can assign an entity in the design to only one Logic Lock region, but the entity can inherit regions by hierarchy. This hierarchy allows a reserved region to have a sub region without reserving the resources in the sub region.

If a Logic Lock region boundary includes part of a device resource, the Quartus Prime software allocates the entire resource to that Logic Lock region.

Figure 110. Chip Planner with Logic Lock Button on Toolbar



6.3.2.1. Defining a Logic Lock Region in Chip Planner

The Chip Planner allows you to easily see Logic Lock region locations and properties in relation to other resources in the device.

Before Analysis and Elaboration, the Chip Planner displays the device floorplan resources that are available. You can define Logic Lock regions in this floorplan. After running Analysis & Elaboration, you can add member nodes to the region.

To draw a Logic Lock region in the Chip Planner:

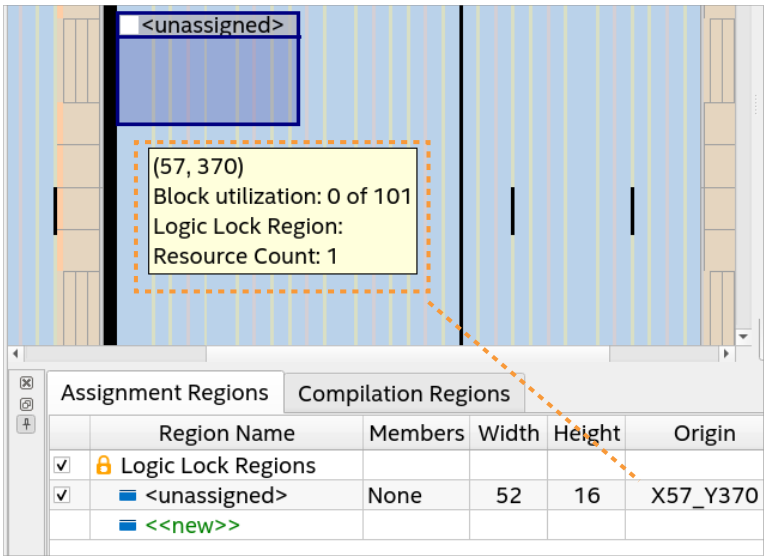
1. Open an Quartus Prime project.
2. Click **Processing ➤ Start ➤ Start Analysis & Elaboration**.

   Note: You can this step if you want to reserve the empty region without adding member nodes yet.
3. To open the Chip Planner, click **Tools ➤ Chip Planner**. Chip Planner opens and loads device resource information.
4. Click the **Create Logic Lock Region** button on the Chip Planner Toolbar.

Figure 111. Create Logic Lock Region Button on Toolbar

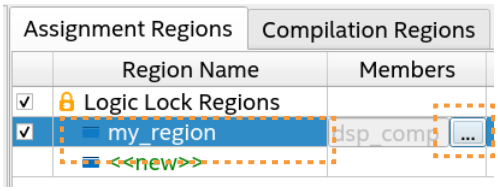
5. To define the region dimensions and location, click and drag the cursor on the Chip Planner floorplan to draw a region of your preferred location and size. An **<<unassigned>>** Logic Lock region appears in the Chip Planner and Logic Lock Regions window at the coordinates you specify.

Figure 112. Drag Cursor to Define Region Location and Size



6. In the Logic Lock Regions window, double-click **<<unassigned>>** and type a descriptive name for the region.
7. To add member nodes to the region, click the **Members** cell, and then click the **(...)** button to search for the nodes you want to add. You must complete step 2 before this step.

Figure 113. Specifying Region Name and Members



8. Confirm or customize the region **Width**, **Height**, and point of **Origin** settings in the Logic Lock Regions window.
9. To prevent the Fitter from placing any other logic in the region, turn on the **Reserved** option. This option is useful for preliminary floorplanning and for reserving device resources for logic to be added later. Otherwise, leave this option off.
10. To exclude periphery device resources from the region, turn on the **Core-Only** option.
11. For region **Size/State**, specify whether you or the Fitter determines the size and placement of the Logic Lock region:
    - If set to **Fixed/Locked**, the default value, you define the Logic Lock region's size and placement.
    - If set to **Auto/Floating**, the Fitter determines the size and placement of the Logic Lock region.
12. For **Routing Region**, specify the type of routing region constraint, such as **Unconstrained**, **Whole Chip**, or **Fixed Width Expansion** options. Refer to Defining Routing Regions on page 173.

6.3.2.1.1. Logic Lock Region Properties

You can view and modify the following properties for the Logic Lock regions that you define. You can access these properties using either of these methods:

- Click **Assignments ➤ Logic Lock Regions Window**.
- Right-click and existing Logic Lock region, and then click **Logic Lock Region Properties**.

Table 42. Attributes of Logic Lock Regions

Option	Values	Behavior
Width	**Number of columns**	Specifies the width of the Logic Lock region. If **Size/State** is set to **Auto/Floating**, the attribute is set to **Undetermined**.
Height	**Number of rows**	Specifies the height of the Logic Lock region. If **Size/State** is set to **Auto/Floating**, the attribute is set to **Undetermined**.
Origin	**Any Floorplan Location**	Specifies the location of the Logic Lock region on the floorplan. The origin is at the lower left corner of the Logic Lock region.
Reserved	Off | On	Prevents the Fitter from placing other logic in the region. Unless enabled, the Fitter fills unoccupied resources with other nodes and entities that have not been assigned to another region. You cannot apply the **Reserved** assignment to routing regions.

continued...

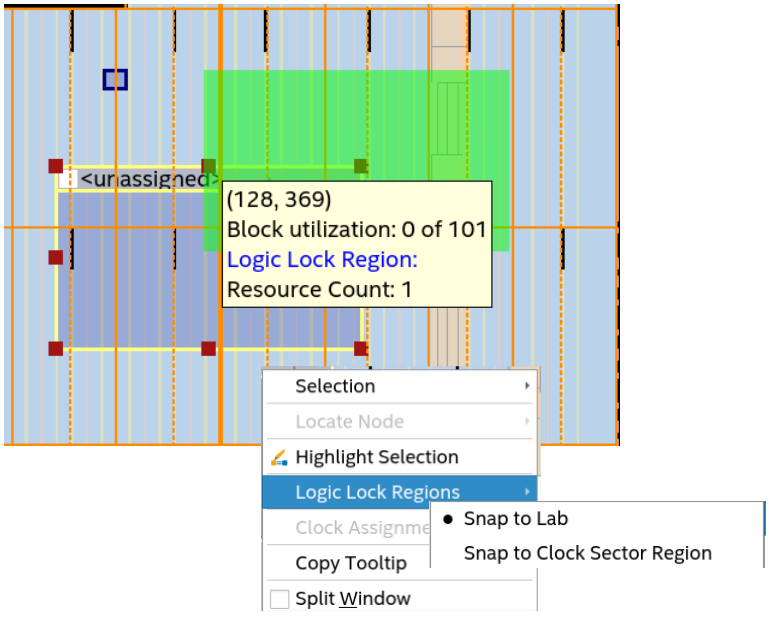
Option	Values	Behavior
Core-Only	Off | On	Excludes periphery resources from a region. Quartus Prime Pro Edition region assignments apply to periphery resources by default. If the region is designated as **Reserved** and **Core Only**, periphery resources are not reserved from the region.
Size/State	**Fixed/Locked** | **Auto/Floating**	Specifies whether you or the Fitter determines the size and placement of the Logic Lock region. • If set to **Fixed/Locked**, the default value, you define the Logic Lock region's size and placement. • If set to **Auto/Floating**, the Fitter determines the size and placement of the Logic Lock region.
Routing Region	**Unconstrained** | **Whole Chip** | **Fixed with Expansion** | **Custom**	The type of routing region constraint, such as **Unconstrained**, **Whole Chip**, or **Fixed Width Expansion** options. For more details, refer to Defining Routing Regions on page 173.

6.3.2.1.2. Snapping to a Region

When placing Logic Lock regions in the Chip Planner by hand, Chip Planner is set to snap the placement of the region to adjacent LAB boundaries by default. This means that as you drag the region to a location, the region snaps to the adjacent lab boundary when you drop the region in the floorplan.

Alternatively, you can click **View ➤ Logic Lock Regions ➤ Snap Logic Lock Region to** to toggle the snapping between **Snap to Lab** or **Snap to Clock Sector Region**. When your turn on **Snap to Clock Sector Region**, orange grid lines appear to show the clock sector region boundaries when you create, resize, or move the region.

Figure 114. Snapped to the Region



- **Creating Region**: Left-click on the mouse to create the Logic Lock region. Upon releasing the mouse, the created Logic Lock region snaps to the containing clock region or sector.
- **Resize region (and resize diagonal)**: Left-click on the mouse and drag the Logic Lock region handle. Upon releasing the mouse, the Logic Lock region resizes and snaps to the containing clock region or sector.
- **Move region**: Select and drag the Logic Lock region to highlight the clock region boundaries. Upon releasing the mouse button, the Logic Lock region moves to the new position and snaps to the containing clock region or sector.
  - **Same place and route regions are moved**: Both Logic Lock regions move and snap to the containing clock sectors.
  - **Only place | route region is moved**: The selected region moves and snaps to the clock sector, and prompts warning if the new location or size of the region does not adhere to 'place bboxes contained within route bboxes' rule.
- **Subtract or make a hole**: When performing subtract in the snap-to-clock-region mode, you create a region where the region is snapped to a clock region or a sector, and then subtract away.

6.3.2.1.3. Considerations for Auto Sized Regions

If you use **Auto/Floating** Size/State Logic Lock regions, consider the following limitations and effects:

- **Auto/Floating** regions cannot be reserved.
- Verify that your Logic Lock region is not empty. If you do not assign any instance to the region, the Fitter reduces the size to 0 by 0, making the region invalid.
- The region may or may not be associated with a partition. When you combine partitions with **Auto/Floating** Size/State Logic Lock regions, you get flexibility to solve your particular fitting challenges. However, every constraint that you add reduces the solutions available, and too many constraints can result in the Fitter not finding a solution. Some cases are:
  - If a partition is preserved at synthesis or not preserved, the Logic Lock region confines the logic to a specific area, allowing the Fitter to optimize the logic within the partition, and optimize the placement within the Logic Lock region.
  - If a partition is preserved at placement, routed, or final; a Logic Lock region is not an effective placement boundary, because the location of the partition's logic is fixed.
  - However, if the Logic Lock region is reserved, the Fitter avoids placing other logic in the area, which can help you reduce resource congestion.
- Once the outcome of the Logic Lock region meets your specification, you can:
  - Convert the Logic Lock region to **Fixed/Locked** Size/State.
  - Leave the Logic Lock region with **Auto/Floating** Size/State attribute and use the region as a “keep together” type of function.
  - If the Logic Lock region is also a partition, you can preserve the place and route through the partition and remove the Logic Lock region entirely.

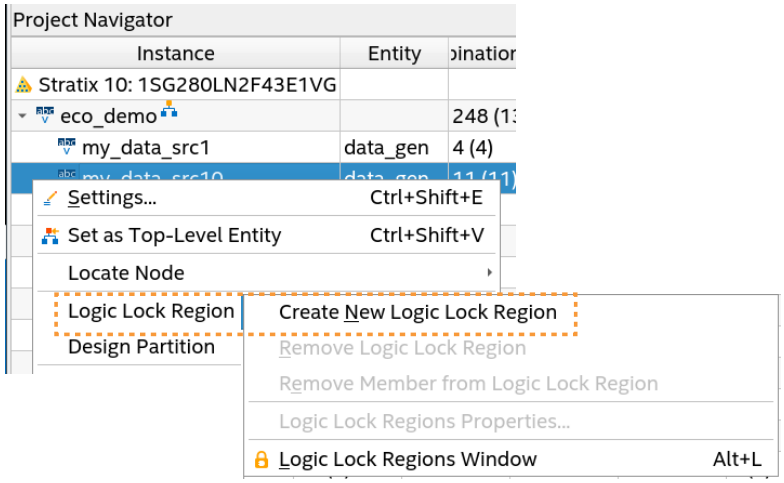
6.3.2.2. Defining a Logic Lock Region from the Project Navigator

After you run Analysis & Elaboration or the Fitter, you can assign the member nodes to the Logic Lock region. The Project Navigator facilitates easy Logic Lock constraint creation and member assignment from your design entities in a single step.

To define a Logic Lock region from the Project Navigator:

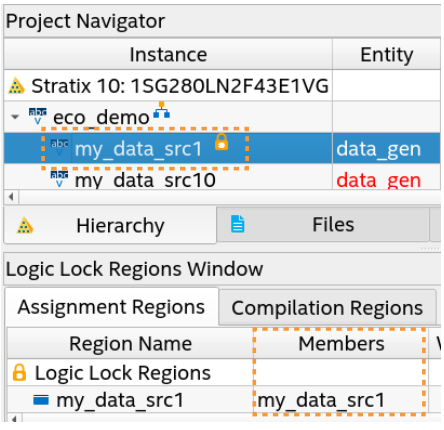
1. Run **Analysis & Elaboration** or the **Fitter (Finalize)** from the Compilation Dashboard. The Project Navigator displays the design hierarchy when complete.
2. Expand the design hierarchy in the Project Navigator, right-click any design entity, and click **Logic Lock Region ➤ Create New Logic Lock Region**.

Figure 115. Create New Logic Lock Region



The new region appears with the assigned node in the Logic Lock Regions window. Modify the **Region Name** and other properties in the Logic Lock Regions window.

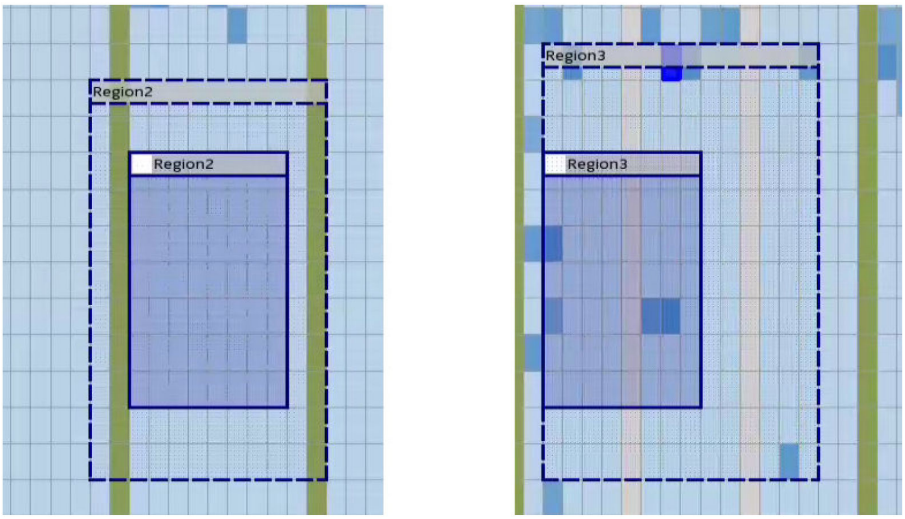
Figure 116. New Logic Lock Region In Logic Lock Regions Window



6.3.2.3. Defining Routing Regions

A routing region is an element of a Logic Lock region that specifies the routing area. A routing region must encompass the existing Logic Lock placement region. Routing regions cannot be set as reserved. To define the routing region, double-click the **Routing Region** cell in the **Logic Lock Regions** window, and select an option from the drop-down menu.

Figure 117. Routing Regions



Fixed with Expansion +2

Custom Routing

Table 43. Routing Region Options

Option	Description
Unconstrained (default)	Allows the Fitter to use any available routes on the device.
Whole Chip	Same result as **Unconstrained**, but writes the constraint in the Quartus Prime settings file (`.qsf`).
Fixed with Expansion	Follows the outline of the placement region. The routing region scales by a number of rows and columns larger than the placement region.
Custom	Allows you to define a custom shape routing region around the Logic Lock region. When you select the **Custom** option, the placement and routing regions move independently in the Chip Planner. In this case, move the placement and routing regions by selecting both using the Shift key.

6.3.2.4. Defining Empty Logic Lock Regions

The Quartus Prime supports the use of Logic Lock regions without any members. You can use such empty regions to reserve device resources to contain logic to be add later. This technique require that you turn on the region's **Reserved** setting to prevent the Fitting from placing any other logic within this region.

Empty Logic Lock regions can be useful for the following scenarios:

- Preliminary floorplanning
- Complex incremental builds, such as root partition reuse
- Team based design and interconnect logic
- Confining logic placements

Since Logic Lock regions do not reserve any routing resources by default, the Fitter may use the reserved area for routing purposes.

Use the **Core Only** attribute for empty Logic Lock regions. When you include periphery resources in empty regions, you restrict the periphery component placement, which can result in a no fit design. After you name the empty region, you can perform the same manipulations as with any Logic Lock region that includes members.

Figure 118. All Logic Placed Outside an Empty region

The figure shows an empty Logic Lock region and the logic placed around it. However, some I/Os, HSSIO, and PLLs are present in the empty region because the output port connects to the I/O that is part of the root_partition (top-level partition).

6.3.2.5. Defining Hierarchical Logic Lock Regions

Logic Lock regions can be fully hierarchical. Parent regions must completely contain all child regions. The **Reserved** and **Core-Only** assignments also apply hierarchically.

Logic Lock assignments follow the same precedence as other constraints and assignments.

You can assign an entity in the design to only one Logic Lock region, but the entity can inherit regions by hierarchy. This hierarchy allows a reserved region to have a sub region without reserving the resources in the sub region.

6.3.3. Customizing the Shape of Logic Lock Regions

To create custom shaped Logic Lock regions, you can perform logic operations. Non-rectangular Logic Lock regions can help you exclude certain resources, or place parts of your design around specific device resources to improve performance.

Attention: There is no undo feature for the Logic Lock shapes for 17.1.

Logic Lock Regions Properties Dialog Box

Use the **Logic Lock Regions Properties** dialog box to view and modify detailed information about your Logic Lock region, such as which entities and nodes are assigned to your region, and which resources are required.

To open the **Logic Lock Regions Properties** dialog box, right-click the region and select **Logic Lock Regions Properties...**.

6.3.3.1. Adding a New Shape to a Logic Lock Region

To add a new shape to an existing Logic Lock region, perform the following steps in the Chip Planner:

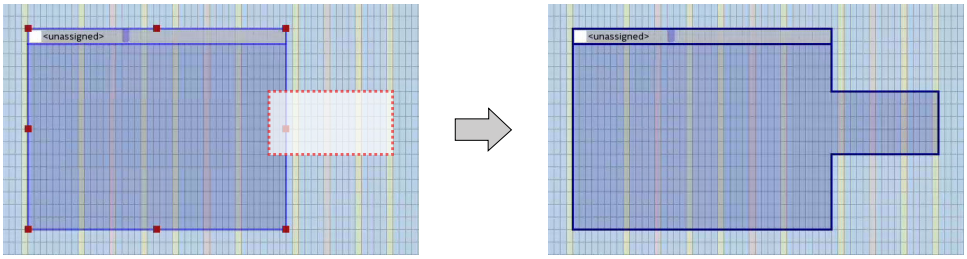
1. Select the Logic Lock region.
2. In the **Navigation** toolbar, click the **Add Logic Lock Region** button.

Figure 119. Add Logic Lock Region Button in Toolbar

3. Click and drag to generate the shape you want to add. The new shape merges automatically with the selected Logic Lock region.

   Attention: If you selected more than one region, the operation appends the new shape to all of the regions.

Figure 120. Using the Add Logic Lock Region Feature

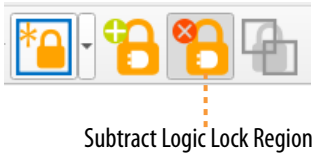


6.3.3.2. Subtracting Shape from Logic Lock Region

To subtract a shape from an existing Logic Lock region, perform the following steps in the Chip Planner:

1. Select the Logic Lock region.
2. In the **Navigation** toolbar, click the **Subtract Logic Lock Region** button.

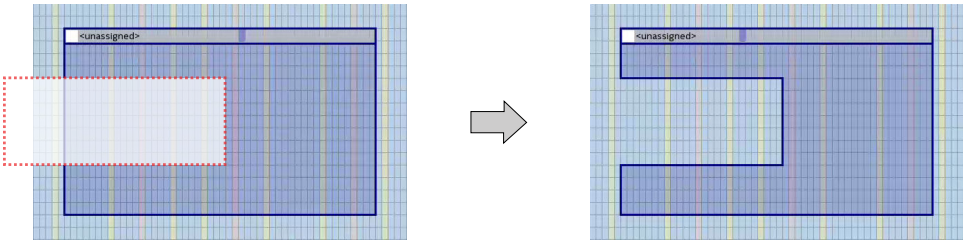
Figure 121. Subtract Logic Lock Region Toolbar Button



3. Click and drag the shape you want to subtract. The modified region displays automatically.

   The operation performs in all selected regions.

Figure 122. Using the Subtract Logic Lock Region Feature



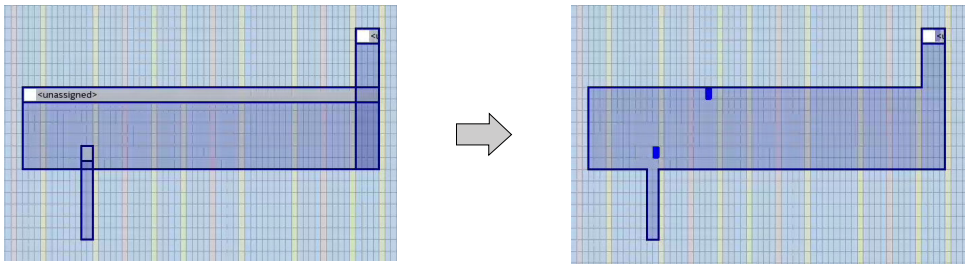
6.3.3.3. Merging Logic Lock Regions

To merge two or more Logic Lock regions, perform the following steps:

1. Ensure that no more than one of the regions that you intend to merge has logic assignments.
2. Arrange the regions into the locations where you want the resultant region.
3. Select all the individual regions that you want to merge by clicking each of them while pressing the Shift key.
4. Right-click the title bar of any of the selected Logic Lock regions and select **Logic Lock Regions ➤ Merge Logic Lock Region**. The individual regions that you select merge to create a single new region.

If you select multiple named regions, the **Merge Logic Lock Region** option is deactivated.

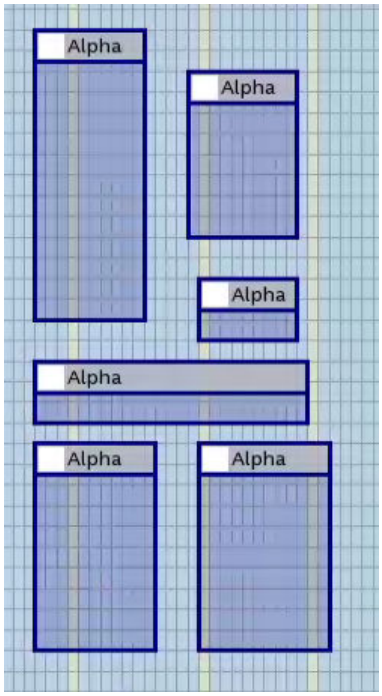
Figure 123. Using the Merge Logic Lock Region command



6.3.3.4. Defining Noncontiguous Logic Lock Regions

You can create disjointed regions by using the Logic Lock region manipulation tools. Noncontiguous regions act as a single Logic Lock region for all Logic Lock region attributes.

Figure 124. Logic Lock Regions in Chip Planner Floorplan



6.3.4. Assigning Device Pins to Logic Lock Regions

A Logic Lock region incorporates all device resources within its boundaries, including memory and pins. The Quartus Prime Pro Edition software does not include pins automatically when you assign an entity to a region, unless the **Core Only** attribute is off.

You can manually assign pins to Logic Lock regions; however, this placement puts location constraints on the region. The software only obeys pin assignments to locked regions that border the periphery of the device. The locked regions must include the I/O pins as resources.

6.3.5. Viewing Connections Between Logic Lock Regions in Chip Planner

You can view and edit Logic Lock regions using the Chip Planner. To view and edit Logic Lock regions, use **Floorplan Editing** in the **Layers Settings** window, or any layers setting mode that has the **User-assigned Logic Lock regions** setting enabled.

The Chip Planner shows the connections between Logic Lock regions. By default, you can view each connection as an individual line. You can choose to display connections between two Logic Lock regions as a single bundled connection rather than as individual connection lines. To use this option, open the Chip Planner and on the View menu, click **Inter-region Bundles**.

Related Information

Inter-region Bundles Dialog Box
For more information about the Inter-region Bundles dialog box, refer to Quartus Prime Help.

6.3.6. Example: Placement Best Practices for Arria 10 FPGAs

Logic Lock regions must take into account the device topology.

This example describes how I/O Columns constrain locations in Logic Lock regions in designs targeting Arria 10 FPGAs.

Figure 125. I/O Columns in Arria 10 FPGAs

Arria 10 FPGAs have I/O columns located in the middle of the device. Signals can only enter or exit these columns from the side that faces the device edge.

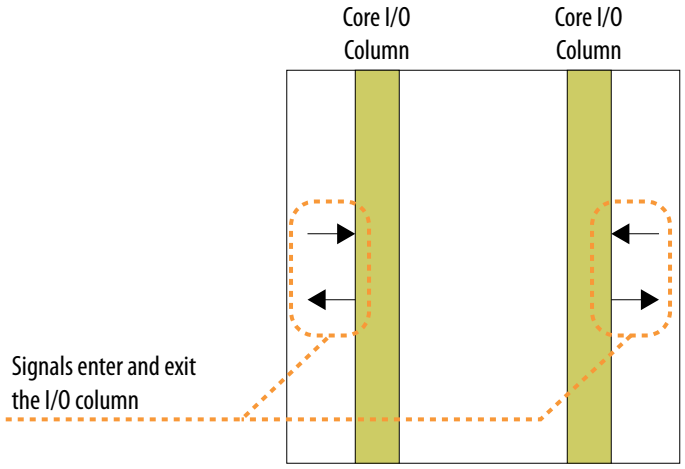


Figure 126. Signals Crossing I/O Columns in Arria 10 FPGAs

Routing a signal to cross the I/O column increases the routing delay, and can reduce design performance.

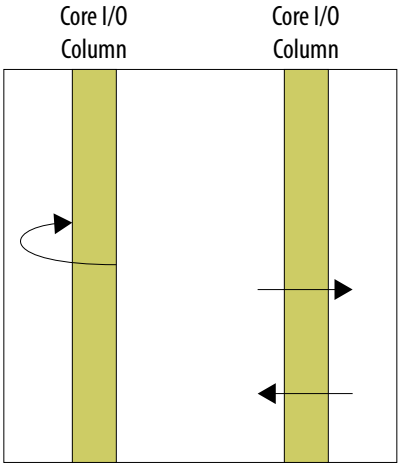

Figure 127. Strategic Placement for Logic Lock Regions in Arria 10 FPGAs

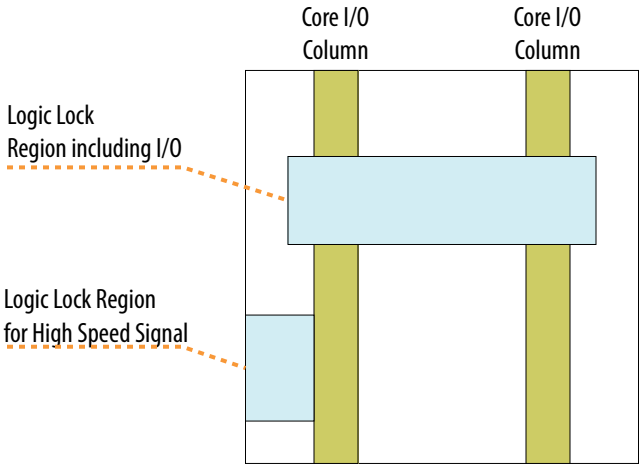
- If a Logic Lock region contains a register that interface with the I/O column, place the Logic Lock region so that the region covers the I/O column and the core logic, for better access to the I/O column adjacent to the outer column edge.
- For high speed signal, you can get best results if you place the Logic Lock region on the outside of the I/O column, because the fitter is less likely to cross the column and incur delay.



6.3.7. Migrating Assignments between Quartus Prime Standard Edition and Quartus Prime Pro Edition

The Quartus Prime Pro Edition software does not support the Quartus Prime Standard Edition Logic Lock (Standard) assignments. Therefore, if you are migrating a design from Quartus Prime Standard Edition to Quartus Prime Pro Edition, you must convert the Logic Lock (Standard) assignments into Logic Lock assignments.

Related Information

Replace Logic Lock Regions
In *Quartus Prime Pro Edition User Guide: Getting Started*

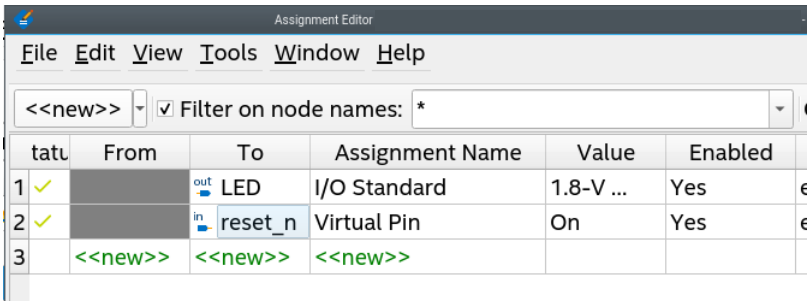
6.4. Defining Virtual Pins

A virtual pin is an I/O element that the Compiler temporarily maps to a logic element, rather than to a pin. The Compiler implements these virtual pins as LUTs.

By making assignments to virtual pins, you can ensure that the Fitter places those pins in the same device region as the corresponding internal nodes in the top-level module. You can apply the **Virtual Pin** option to successfully compile a Logic Lock module that has more pins than the target device. The **Virtual Pin** option can enable timing analysis of a design module that more closely matches the performance of the module after you integrate it into the top-level design.

You can create and assign virtual pins to an I/O element using the **Virtual Pin** logic option in the Assignment Editor (**Assignments ➤ Assignment Editor**).

Figure 128. Virtual Pin Logic Option in the Assignment Editor



When you apply the **Virtual Pin** assignment to an input pin, the pin no longer appears as an FPGA pin. Rather, the Compiler fixes the virtual pin to GND in the design. The virtual pin is not a floating node.

Use virtual pins only for I/O elements in lower-level design entities that become nodes after you import the entity to the top-level design; for example, when compiling a partial design. In the top-level design, you connect these virtual pins to an internal node of another module

Note: You must assign the **Virtual Pin** logic option to an input or output pin. If you assign this option to a bidirectional pin, tri-state pin, or registered I/O element, synthesis ignores the assignment. If you assign this option to a tri-state pin, the Fitter inserts an I/O buffer to account for the tri-state logic; therefore, the pin cannot be a virtual pin. You can use multiplexer logic instead of a tri-state pin if you want to continue to use the assigned pin as a virtual pin. Do not use tri-state logic except for signals that connect directly to device I/O pins.

To display all assigned virtual pins in the design with the Node Finder, you can set **Filter Type** to **Pins: Virtual**. To access the Node Finder from the Assignment Editor, double-click the **To** field; when the arrow appears on the right side of the field, click and select **Node Finder**.

Related Information

Assigning Virtual Pins with a Tcl command on page 190

6.5. Using Logic Lock Regions in Combination with Design Partitions

You can optimize timing in a design by placing entities that share significant logical connectivity close to each other on the device.

By default, the Fitter attempts to place closely connected entities in the same area of the device. However, without constraint, this same placement is not assured for each compilation. You can use Logic Lock regions, together with design partitions, to ensure that logically connected entities retain optimal placement from one compilation to the next.

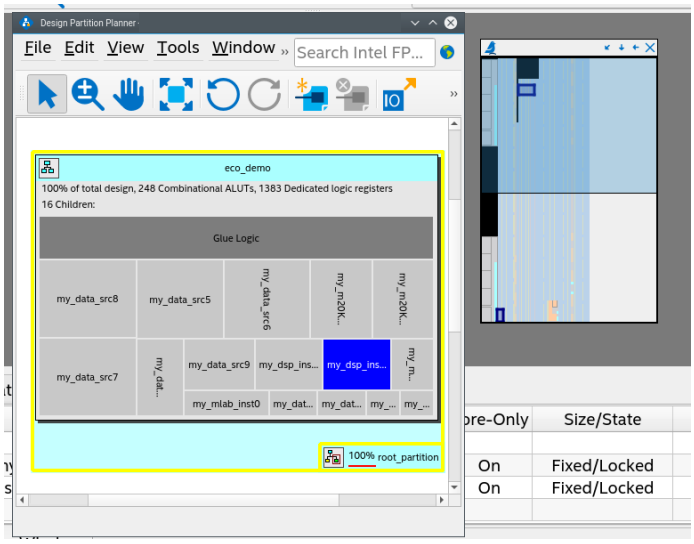
Using Logic Lock regions in combination with design partitions allows you to preserve the location and performance of a block, so that the Fitter focuses time and effort on other portions of the design.

Note: For more details about these techniques, refer to *Quartus Prime Pro Edition User Guide: Block-Based Design*

To use the Design Partition Planner in conjunction with the Chip Planner to readily create partitions and define Logic Lock regions, follow these steps:

1. On the Compilation Dashboard, double-click **Plan** to compile through that Fitter stage, or run a full compilation.
2. Open the Chip Planner and the Design Partition Planner:
   - Click **Tools ➤ Chip Planner**
   - Click **Tools ➤ Design Partition Planner**
3. In the Chip Planner, double-click **Report Design Partitions** in the **Tasks** pane. The Chip Planner displays the physical locations of design partitions using the same colors as the entities in the Design Partition Planner.

Figure 129. Design Partition Planner Overlaying Chip Planner



4. In the Chip Planner, click **View ➤ Bird's Eye View**

5. In the Design Partition Planner, drag all the larger entities out from their parents. Alternatively, you can right-click the entity and click **Extract from Parent**. The Chip Planner displays the physical placement of the entities shown in the Design Partition Planner, with consistent colors between the two tools. You can view physical placement in the Chip Planner and connectivity in the Design Partition Planner.
6. Identify entities that are unsuitable to place in Logic Lock regions:
   - The Chip Planner shows an entity to be physically dispersed over noncontiguous areas of the device.
   - The Design Partition Planner shows an entity to have a large number of connections to other entities.
7. Drag the entities that are unsuitable for placement in Logic Lock regions back to the parent entities. Alternatively, right-click the entity and click **Collapse to Parent**.
8. Create a partition for each remaining entity by right-clicking the entity, and then clicking **Create Design Partition**.
9. Create a Logic Lock region for each partition by right-clicking the partition, and then clicking **Create Logic Lock Region**.

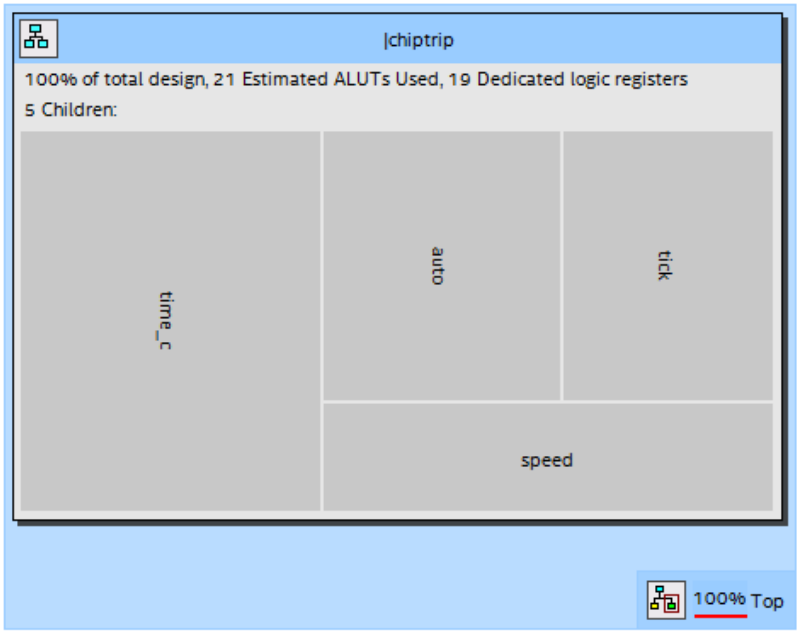
6.5.1. Viewing Design Connectivity and Hierarchy

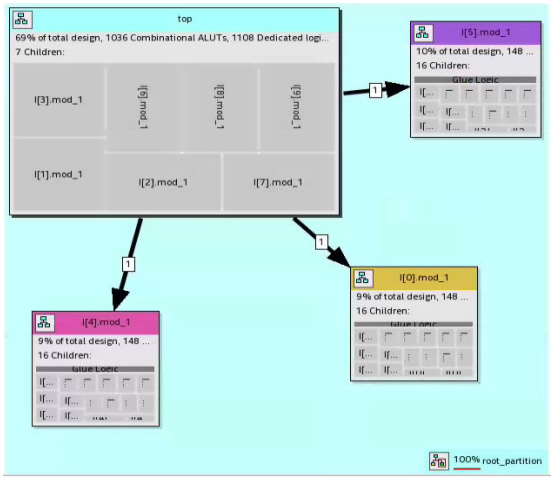
By default, when you open a compiled design, the Design Partition Planner displays the design as a single top-level entity, containing lower-level entities. If the Design Partition Planner has opened the design previously, the design appears in its last state.

Figure 130. Top-Level Entity in the Design Partition Planner



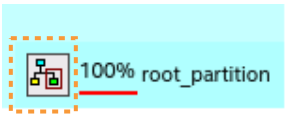
- To show connectivity between entities, extract entities from the top-level entity by dragging them into the surrounding white space, or by right-clicking an entity and clicking **Extract from Parent** on the shortcut menu.
  When you extract entities, Design Partition Planner draws the connection bundles between entities, showing the number of connections between pairs of entities.

Figure 131. Partitioned Design with Connection Bundles



- To customize the appearance of connection bundles or to set thresholds for connection counts, click **View ➤ Bundle Configuration**, and set the necessary options in the **Bundle Configuration** dialog box.
- To see bundles containing failing paths, open the Timing Analyzer, and then click **View ➤ Show Timing Data** in the Design Partition Planner. Bundles containing failing paths are displayed in red, as are entities having nodes that reside on failing paths.
- To see detailed information about the connections in a bundle, right-click the bundle, and then click **Bundle Properties** to open the **Bundle Properties** dialog box.
- To switch between connectivity display mode and hierarchical display mode, click **View ➤ Hierarchy Display**. Alternatively, click and hold the hierarchy button in the top-left corner of any entity to switch temporarily to a hierarchy display.

Figure 132. Hierarchy Display Button



6.6. Creating Clock Region Assignments in Chip Planner

You can easily create and manipulate clock regions in the Chip Planner and make clock assignments to the regions.

You can create a user-defined clock region assignment to ensure that a given global clock signal is available to resources in a certain area of the device throughout all design iterations. In instances of congestion involving global signal resources, you may specify a smaller clock region assignment to prevent a signal from using congested clock resources in other sectors.

If you create user-defined clock regions and subsequently compile the design, those user-defined clock regions become Fitter-defined clock regions, and are read-only.

Summary of User-Defined Clock Region Feature Support

Feature	Clock Region Support
Shapes of clock regions	Limited to rectangular regions that snap to clock sector grids.
Peripheral element assignments	Limited to clocking design elements.
Clock region name	Identified by the source clocking design element.
Support for multiple instances per region	Create one region per clock design element, and then specify the same definition for multiple clock design elements to assign to the same clock region.

Using Clock Region Assignments in Stratix 10 and Agilex 7 Devices

You can constrain clock regions to a rectangle whose dimensions are defined by the sector grid, as seen in the **Clock Sector Region** layer of the Chip Planner. The rectangle is defined by the coordinates of its bottom-left and top-right corners. For example, *SX0, SY0, SX1, SY1* constrains the clock to a 2 × 2 region, from the bottom left of sector 0,0 to the top right of sector 1,1.

You can alternatively specify the bounding rectangle in chip coordinates, for example *X37 Y181 X273 Y324*. However, you should sector-align such a constraint. The Fitter automatically snaps to the smallest sector-aligned rectangle that encompasses the original assignment.

6.6.1. Creating Clock Assignments in Chip Planner

To create clock assignments with the Chip Planner, follow these steps:

1. Select the **Create Clock Assignment** button, or click **View ➤ Clock Assignments ➤ Create Clock Assignment**.

Figure 133. Create Clock Assignment Button on Chip Planner Toolbar

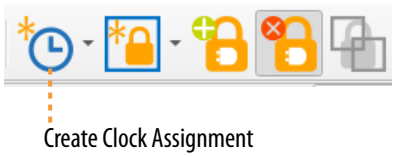


Figure 134. Newly Created Clock Region

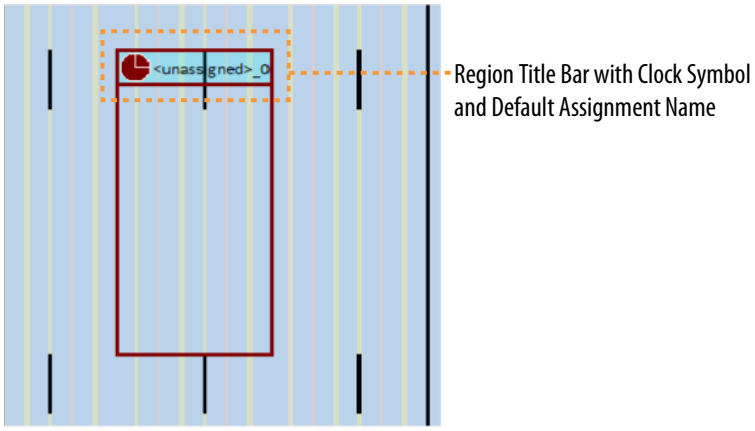


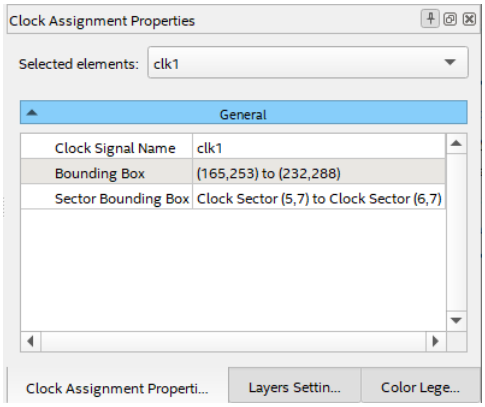
2. Click and drag the mouse on the Chip Planner floorplan to draw a clock region of your preferred location and size. The region that you draw snaps to the smallest clock sector capable of containing the region. Orange clock sector grids help visualize positioning of the clock region relative to clock sectors.
3. Assign a clock signal from the context menu. A clock symbol in the region title bar identifies a clock region. The clock region is unassigned until you assign a clock signal from the context menu.

6.6.1.1. Clock Assignment Properties

The **Clock Assignment Properties** pane displays properties of the selected clock assignment.

By default, the **Clock Assignment Properties** pane appears on a tab at the right side of the Chip Planner.

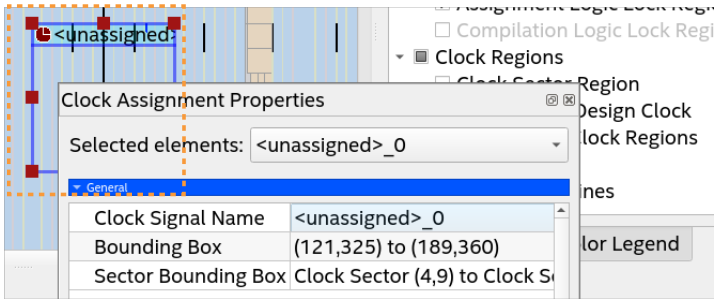
Figure 135. Clock Assignment Properties Pane



6.6.2. Resizing a Clock Assignment in Chip Planner

To resize an existing clock assignment in the Chip Planner, follow these steps:

Figure 136. Clock Assignment in Chip Planner



1. Select an existing clock assignment in the Chip Planner floorplan. Handles appear on each side of the region and at the corners.
2. Position the crosshairs over the handle of your choice and the resize mouse cursor appears.
3. Hold the left mouse button and drag the resize cursor to expand or shrink the boundary of the clock assignment. When you release the mouse button, the clock assignment boundaries snap to the nearest containing clock sector grid.

6.6.3. Moving a Clock Assignment in Chip Planner

To move a clock assignment in the Chip Planner, follow these steps:

1. Select the clock assignment in the Chip Planner floorplan.
2. Position the crosshairs over the clock assignment title bar and the move cursor appears.
3. Hold the left mouse button and drag the clock assignment to the new location.

6.6.4. Deleting a Clock Region Assignment in Chip Planner

To delete a clock region assignment in the Chip Planner, follow these steps:

1. Select the clock assignment that you want to delete in the Chip Planner floorplan.
2. Right-click the clock assignment title bar to display the context menu, or select **View** from the main menu bar.
3. Click **Clock Assignments ➤ Delete Clock Assignment**.
4. You are prompted to confirm that you want to delete the selected clock assignment. Click **Yes** to confirm the deletion.

The specified clock region assignment is deleted from the system.

6.6.5. Assigning a Clock Signal to a Clock Region in Chip Planner

To assign a clock signal to a clock region in the Chip Planner, follow these steps:

1. Right-click the clock assignment title bar to display the context menu, or select **View** from the main menu bar in the Chip Planner.
2. Click **Clock Assignments ➤ Set Clock Signal Name**.
3. In the **Set Clock Signal Name** dialog box, browse to or type the desired clock signal name.
4. Click **Ok**.

The system renames the clock assignment according to the name of the specified clock signal.

6.7. Scripting Support

You can run the commands and specify the settings described in this chapter as part of a Tcl script. You can also run some commands at a command prompt. The following topics describe the commands.

Related Information

Quartus Prime Pro Edition User Guide: Scripting

6.7.1. Creating Logic Lock Assignments with Tcl commands

The Quartus Prime software supports Tcl commands to create or modify Logic Lock assignments.

Note: Specify node names by using the full hierarchy path to the node.

Create or Modify a Placement Region

You can create the Logic Lock region from the GUI, or add the region directly to the QSF. The QSF entry contains the X/Y coordinates of the vertices and the Placement Region name.

The following assignment creates a new placement region with bounding box coordinates `X46 Y36 X65 Y49`:

```
set_instance_assignment -name PLACE_REGION "X46 Y36 X65 Y49" -to <node names>
```

- You can use the same command format to modify an existing assignment.
- To specify a non-rectangular or disjoint region, use a semicolon (`;`) as the delimiter between two or more bounding boxes.
- Assign multiple instances to the same region with multiple `PLACE_REGION` instance assignments.

Create or Modify a Routing Region

The following assignment creates a routing region with bounding box coordinates `X5 Y5 X30 Y30`:

```
set_instance_assignment -name ROUTE_REGION -to <node names> "X5 Y5 X30 Y30"
```

- You can use the same command format to modify an existing assignment.
- All instances with a routing region assignment must have a respective placement region; the routing region must fully contain the placement region.

Specify a Region as Reserved

The following assignment reserves an existing region:

```
set_instance_assignment -name <instance name> RESERVE_PLACE_REGION -to <node
names> ON
```

- You can only reserve placement regions.

Specify a Region as Core Only

By default, the Quartus Prime Pro Edition software includes pins in Logic Lock assignments. To specify a region as core only (that is, periphery logic in the instance that is not constrained), use the following assignment:

```
set_instance_assignment -name <instance name> CORE_ONLY_PLACE_REGION -to <node names> ON
```

Related Information

Defining Logic Lock Regions on page 167

6.7.2. Assigning Virtual Pins with a Tcl command

Use the following Tcl command to turn on the virtual pin setting for a pin called `my_pin`:

```
set_instance_assignment -name VIRTUAL_PIN ON -to my_pin
```

Related Information

Defining Virtual Pins on page 180

6.7.3. Logic Lock Region Assignment Examples

The following examples show the syntax of Logic Lock region assignments in the `.qsf` file. Optionally, you can enter these assignments in the Assignment Editor, the Logic Lock Regions Window, or the Chip Planner.

Example 1. Assign Rectangular Logic Lock Region

Assigns a rectangular Logic Lock region to a lower left corner location of (10,10), and an upper right corner of (20,20) inclusive.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
```

Example 2. Assign Non-Rectangular Logic Lock Region

Assigns instance with full hierarchical path "x|y|z" to non-rectangular L-shaped Logic Lock region. The software treats each set of four numbers as a new box.

```
set_instance_assignment –name PLACE_REGION –to x|y|z "X10 Y10 X20 Y50; X20 Y10 X50 Y20"
```

Example 3. Assign Subordinate Logic Lock Instances

By default, the Quartus Prime software constrains every child instance to the Logic Lock region of its parent. Any constraint to a child instance intersects with the constraint of its ancestors. For example, in the following example, all logic beneath "a|b|c|d" constrains to box (10,10), (15,15), and not (0,0), (15,15). This result occurs because the child constraint intersects with the parent constraint.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
set_instance_assignment –name PLACE_REGION –to a|b|c|d "X0 Y0 X15 Y15"
```

Example 4. Assign Multiple Logic Lock Instances

By default, a Logic Lock region constraint allows logic from other instances to share the same region. These assignments place instance c and instance g in the same location. This strategy is useful if instance c and instance g are heavily interacting.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
set_instance_assignment –name PLACE_REGION –to e|f|g "X10 Y10 X20 Y20"
```

Example 5. Assigned Reserved Logic Lock Regions

Optionally reserve an entire Logic Lock region for one instance and any of its subordinate instances.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
set_instance_assignment –name RESERVE_PLACE_REGION –to a|b|c ON

# The following assignment causes an error. The logic in e|f|g is not
# legally placeable anywhere:
# set_instance_assignment –name PLACE_REGION –to e|f|g "X10 Y10 X20 Y20"

# The following assignment does *not* cause an error, but is effectively
# constrained to the box (20,10), (30,20), since the (10,10),(20,20) box is
reserved
# for a|b|c
set_instance_assignment –name PLACE_REGION –to e|f|g "X10 Y10 X30 Y20"
```

6.8. Analyzing and Optimizing the Design Floorplan Revision History

The following revision history applies to this chapter:

Table 44. Document Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2023.12.04	23.4	• Added new *Location Assignment Optimization Guidelines* topic.
2023.08.01	23.2	• Replaced missing graphics in *Analyzing Connections for a Path*. • Replaced missing graphics in *Navigating with the Bird's Eye View*. • Replaced missing graphics in *Viewing Immediate Fan-In and Fan-Out in Chip Planner*. • Replaced missing graphics in *Show Delays*. • Replaced missing graphics in *Starting the Chip Planner*. • Replaced missing graphics in *Adding a New Shape to a Logic Lock Region*. • Replaced missing graphics in *Creating Clock Assignments in Chip Planner*. • Replaced missing graphics in *Viewing Fan-In and Fan-Out in Chip Planner*. • Replaced missing graphics in *Viewing Design Connectivity and Hierarchy*. • Replaced missing graphics in *Subtracting Shape from Logic Lock Region*.
2023.04.03	23.1	• Updated product family name to "Intel Agilex 7."

continued...

Document Version	Quartus Prime Version	Changes
2022.09.26	22.3	• Updated chapter for new Compilation Regions tab in the Logic Lock Regions window. This read-only tab displays the properties of any Logic Lock regions contained in a .qdb file in the current project.
2022.01.07	21.4	• Added Properties tab information to *Viewing Architecture-Specific Design Information* topic. • Added Design Assistant information to *Using Logic Lock Regions in the Chip Planner* topic. • Added new *Viewing the Location and Utilization of Device Resources in Chip Planner* topic. • Added new *Viewing Module Placement by Cross-Probing to Chip Planner* topic. • Added new *Finding Design Elements in the Chip Planner* topic. • Added new *Find In Options* topic.
2019.07.30	19.3.0	Added new *Using User-Defined Clock Regions in the Chip Planner* section.
2019.07.01	19.1.0	Added new "Snapping to a Region" topic that describes the **Snap Logic Lock Region to** option.
2019.04.01	19.1.0	• Added new "Viewing Selected Contents" topic that describes a new report listing selected design elements.
2018.09.24	18.1.0	• Added topic: *Viewing Clock Sector Utilization* • Added topic: *Viewing the Source and Destination of Placed Nodes*. • Renamed topic: *Generating Fan-In and Fan-Out Connections* to *Viewing Fan-In and Fan-Out Connections of Placed Resources*.
2018.05.07	18.0.0	• Added recommendations for using iterative methods for floorplanning.
2017.11.06	17.1.0	• Changed instances of *LogicLock Plus* to *Logic Lock*. • Added support for auto-sized Logic Lock regions. • Added support for empty Logic Lock regions. • Added topics: Considerations on Using Auto Sized Regions, Creating Partitions and Logic Lock Regions with the Design Partition Planner and Chip Planner.
2017.05.08	17.0.0	• Chapter reorganization and content update. • Added figures: Clock Regions, Path List in the Locate History Window, Show Physical Routing, Using the Add Rectangle Feature, Using the Subtract Rectangle Feature, Creating a Hole in a LogicLock Region, Noncontiguous LogicLock Region, Routing Regions, Logic Placed Outside of an Empty Region. • Updated figures: HSSI Channel Blocks, Highlight Routing, High-Speed and Low Power Tiles in an Arria 10 Device, Show Delays Highlight Routing, Viewing Assignments in the Chip Planner, LogicLock Plus Regions Window, Using the Merge LogicLock Plus Region Command. • Created topics: *Adding Rectangle to a LogicLock Plus Region*, *Subtracting Rectangle from a LogicLock Plus Region*. • Moved topic: *Viewing Critical Paths* to *Timing Closure and Optimization* chapter and renamed to *Critical Paths*. • Renamed topic: *Creating Non-Rectangular LogicLock Plus Regions* to *Merging LogicLock Plus Regions*. • Renamed topic: *Chip Planner Overview* to *Design Floorplan Analysis in the Chip Planner*. • Renamed chapter from *Analyzing and Optimizing the Design Floorplan with the Chip Planner* to *Analyzing and Optimizing the Design Floorplan*.
2016.10.31	16.1.0	• Implemented Intel rebranding. • Added topic describing how to create a hole in a LogicLock Plus region.
2016.05.02	16.0.0	Updated information on creating LogicLock Plus regions.

continued...

Document Version	Quartus Prime Version	Changes
2015.11.02	15.1.0	• Changed instances of *Quartus II* to *Quartus Prime*. • Added information on how to use LogicLock regions.
2015.05.04	15.0.0	Added information about color coding of LogicLock regions.
2014.12.15	14.1.0	Updated description of Virtual Pins assignment to clarify that assigned input is not available.
June 2014	14.0.0	Updated format
November 2013	13.1.0	Removed HardCopy device information.
May 2013	13.0.0	Updated "Viewing Routing Congestion" section Updated references to Quartus UI controls for the Chip Planner
June 2012	12.0.0	Removed survey link.
November 2011	11.0.1	Template update.
May 2011	11.0.0	• Updated for the 11.0 release. Edited "LogicLock Regions" Updated "Viewing Routing Congestion" Updated "Locate History" Updated Figures 15-4, 15-9, 15-10, and 15-13 Added Figure 15-6
December 2010	10.1.0	• Updated for the 10.1 release.
July 2010	10.0.0	• Updated device support information • Removed references to Timing Closure Floorplan; removed "Design Analysis Using the Timing Closure Floorplan" section • Added links to online Help topics • Added "Using LogicLock Regions with the Design Partition Planner" section • Updated "Viewing Critical Paths" section • Updated several graphics • Updated format of Document revision History table
November 2009	9.1.0	• Updated supported device information throughout • Removed deprecated sections related to the Timing Closure Floorplan for older device families. (For information on using the Timing Closure Floorplan with older device families, refer to previous versions of the Quartus Prime Handbook, available in the Documentation Archive.) • Updated "Creating Nonrectangular LogicLock Regions" section • Added "Selected Elements Window" section • Updated table 12-1
May 2008	8.0.0	• Updated the following sections: "Chip Planner Tasks and Layers" "LogicLock Regions" "Back-Annotating LogicLock Regions" "LogicLock Regions in the Timing Closure Floorplan" • Added the following sections: "Reserve LogicLock Region" "Creating Nonrectangular LogicLock Regions" "Viewing Available Clock Networks in the Device" • Updated Table 10–1 • Removed the following sections: Reserve LogicLock Region Design Analysis Using the Timing Closure Floorplan

7. Using the ECO Compilation Flow

In a typical FPGA project development cycle, the specification of the programmable logic portion of the design can change during the design process. The Quartus Prime software supports these last-minute, targeted *engineering change orders* (ECOs), even after full compilation is complete.

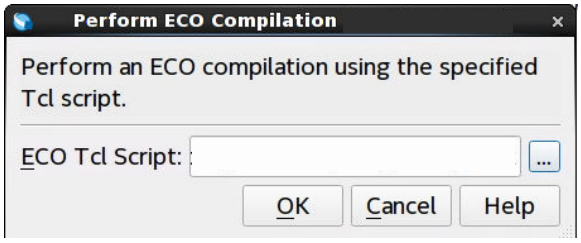
ECOs typically occur during the design verification stage. For example, during verification you may determine that the design requires a small change, such as a netlist connection change, correcting a LUT logic error, or placing a node in a new location. Implementing an ECO change, rather than changing RTL and fully recompiling the design, requires significantly less time, and changes only the affected logic.

You specify the ECO commands in a Tcl script using the `::quartus::eco` package.

Note: The Quartus Prime Pro Edition software supports ECOs for Stratix 10 and Agilex 7 devices only.

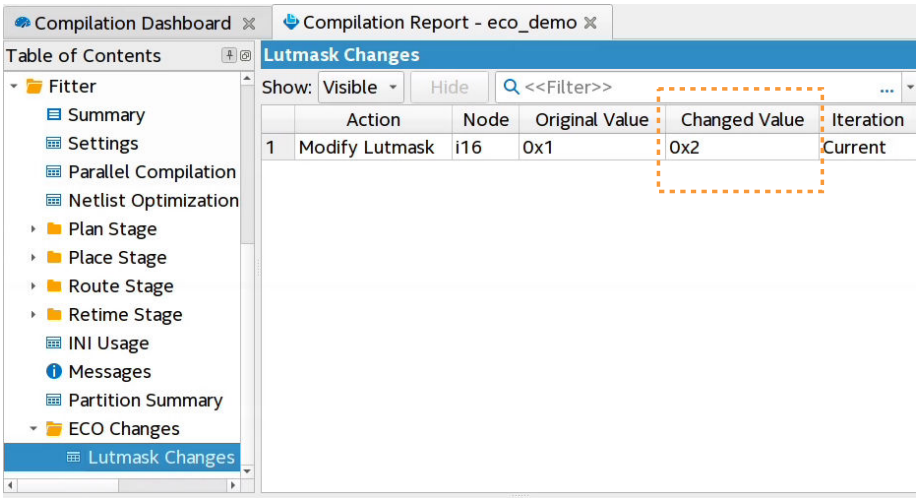
7.1. ECO Compilation Flow

1. Identify an ECO modification you want to make in a compiled design.
2. Determine if ECO commands support the change, by reviewing ECO Commands on page 197 and ECO Command Limitations on page 205.
3. Create a Tcl script, as ECO Tcl Script Example on page 195 shows.
4. Before running ECO compilation, click **Project ➤ Archive Project** and archive the compilation database and output file set.
5. Click **Processing ➤ Start ➤ Perform ECO Compilation**.



6. Specify the **ECO Tcl Script** file, and click **OK**. The Fitter processes the ECO commands and updates the finalized netlist. The Fitter generates an error if you specify any commands incorrectly. The changes apply when the Fitter processing completes.
7. View the ECO results in post-fit analysis tools, such as the Compilation Report, Timing Analyzer, Netlist Viewer, or Chip Planner. To view ECO changes in the Fitter report, click **Processing ➤ Compilation Report ➤ Fitter ➤ ECO Changes**.

Figure 137. Example of ECO Changes Report



As an alternative to the GUI methods, you can use the following commands to run the ECO Tcl scripts. If running from command line, any active Quartus Prime GUI application does not refresh. Close and reopen the project to refresh the GUI.

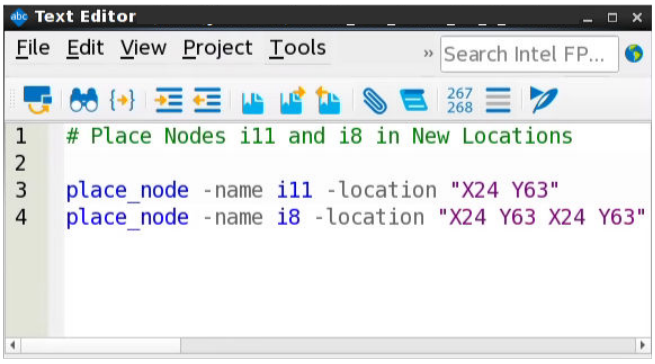
```
$ quartus_fit -s
load_package eco
project_open <project_name>
eco_load_design
...
eco_commit_design
project_close
```

Note: If you rerun the Fitter on a design after implementing an ECO, the Fitter overwrites the ECO changes. Update RTL, IP parameters, and recompile the design to permanently implement the ECO changes.

7.2. ECO Tcl Script Example

The following shows an example ECO Tcl script that places existing nodes in new locations:

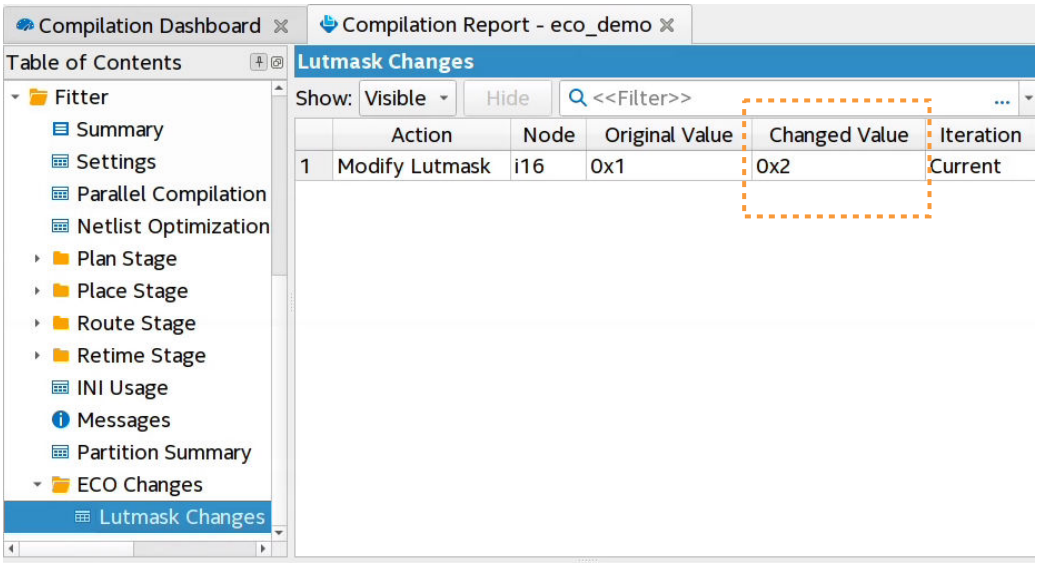
Figure 138. ECO Tcl Script Example



7.3. Viewing ECO Compilation Reports

The Compiler generates a report showing the details of each ECO compilation that you run successfully. You can view the report contents in the **ECO Changes** report under **Fitter** in the Compilation Report.

Figure 139. Example of ECO Changes Report



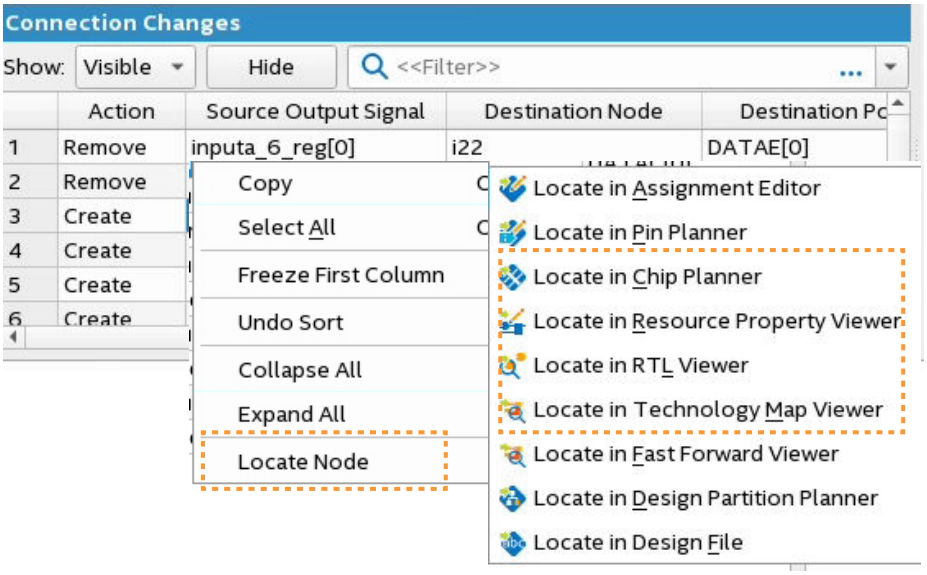
Alternatively, you can view this data in the generated `fit.eco` file. The Compiler organizes the report output according to the category of ECO change, such as Placement Changes. The table specifies the "Changes in Previous ECO Runs" and "Changes in Current ECO Run".

Figure 140. ECO Report Example

```
+-----------------------------------------+
; Placement Changes                       ;
+------------------+----------+-----------+
; Name             ; Location ; Iteration ;
+------------------+----------+-----------+
; GND~ECO_INSERTED ; X78_Y72  ; Previous  ;
; new_node         ; X78_Y72  ; Previous  ;
; new_wirelut      ; X78_Y72  ; Previous  ;
; new_wirelut      ; X24_Y24  ; Current   ;
+------------------+----------+-----------+
```

Locate nodes from the Fitter's ECO reports to confirm ECO changes.

Figure 141. Locate Node from Fitter ECO Reports



7.4. ECO Commands

The Quartus Prime Pro Edition software supports the following ECO commands:

Note: Check available arguments by running `<eco_command> -h|help|long_help`.

7.4.1. ECO Command Quick Reference

Table 45. ECO Command Quick Reference

ECO Change	ECO Commands
Route	`make_connection -from <src> -to <dst> -port <port>` `remove_connection -from <src> -to <dst> -port <port>`
Tie-Off	`make_connection –tieoff <VCC/GND> -to <node> -port <port>`
Lutmask	`modify_lutmask -to <node> [-eqn <lut equation>] [-mask 0x00]`
Slew Rate	`modify_io_slew_rate <value> -to <pin_name>`
Current Strength	`modify_io_current_strength <value> -to <pin_name>`
Delay Chains	`modify_io_delay_chain <value> -type <io_type> -to <pin_name>`
Update MIF	`update_mif_files`
IOPLL Ref Clock (Stratix 10 devices only)	`adjust_pll_refclk -to <pll name> -refclk <freq>`
Create New Node	`create_new_node -type <LUT|FF> -name <name>`
Remove Node	`remove_node -name <name>`
Place Node	`place_node -name <name> [-location <location>]`
Unplace Node	`unplace_node -name <name>`
Create Wirelut	`create_wirelut -from <src> -to <dst> -port <port> [-location <location>]`

7.4.2. make_connection

Description

Connects the source signal to the destination block port. If the port has an existing connection, the command removes the previous connection and connects it to the signal you specify. The actual routing change occurs implicitly when appropriate. You can locate node names by right-clicking a node in Netlist Viewer, and then clicking **Properties**.

`make_connection` also supports adding connections from and to Hyper-Registers. In the case of Hyper-Registers, the command first disconnects the destination port, before making a new connection. You can the run the `make_connection` command to specify a replacement signal source or destination.

If a port is shared among multiple RAM slice atoms, then the ECO Fitter automatically updates all relevant atoms, and reports them accordingly.

Usage

The following example connects `top|a_out` to the D input port of node `top|x`.

```
make_connection -from top|a_out -to top|x -port D
```

Arguments

from Output net of the source block of the new connection.

to Name of the destination block.

port The input port name of the destination block.

Options

tieoff To explicitly tie off an input port to VCC or GND.

VCC or GND

Example:

```
make_connection –tieoff VCC –to {node1} –port DATAA
```

to Name of the destination block.

port The input port name of the destination block.

7.4.3. remove_connection

Description

Disconnects the `src` signal from the destination block port. The actual routing change occurs implicitly. You can locate node names by right-clicking a node in Netlist Viewer, and then clicking **Properties**.

If a port is shared among multiple RAM slice atoms, then the ECO Fitter automatically updates all relevant atoms, and reports them accordingly.

Usage

The following example disconnects `top|a_out` from the D input port of node `top|x`, and set `top|x:D` to a disconnected state.

```
remove_connection -from top|a_out -to top|x -port D
```

Arguments

from Output net of the source block of the current connection.

to Name of the destination block.

port The input port name of the destination block.

7.4.4. modify_lutmask

Description

Modifies the lutmask of the matching destination node, with the lutmask value (`-mask`) in binary or hexadecimal, or with the equivalent lutmask value (`-eqn`) computed from specified logical equation.

Usage

The following example disconnects `top|a_out` from the D input port of node `top|x`, and set `top|x:D` to a disconnected state.

```
modify_lutmask -to top|lut_c -eqn {a&b&c}
modify_lutmask -to top|lut_a -mask 0xFF00FF00
modify_lutmask -to top|lut_b -mask 0b111111111001010
```

Arguments

eqn The logical equation of the inputs (`A, B, C, D, E, F`). The supported lexical tokens include `AND('&')`, `OR('|')`, `XOR('^')`, `NOT('!')`, `OPEN_BRACE('(')`, `CLOSE_BRACE(')')`. Specify `-mask` or `-eqn`

to Destination atom name.

mask The lutmask value to be modified in binary or hexadecimal format. Specify `-mask` or `-eqn`

Note: When you view the lutmask equations in the Resource Property Viewer, the equations display in terms of `F0/F1/F2/F3` LUTs for `A`, `B`, `C` and `D` inputs. For LUTs also using `E` or `F` inputs, you must combine these sub-functions using the connectivity that the ALM diagram shows for the `E` and `F` muxes.

7.4.5. adjust_pll_refclk

Description

Changes the IOPLL frequencies by modifying the input reference clock frequency. The following stipulations apply:

- Maintain the original refclk and outclk ratios.
- The IOPLLs you change cannot generate IP clocks.
- Cascaded IOPLLs must connect directly (no clock gates in between them).
- IOPLLs cannot be in 'nondedicated' compensation modes.
- For all IOPLLs, outclks duty cycle equals 50 and phase shift equals 0.
- No support for Agilex 7 devices.

Usage

The following example adjusts the `*pll_main*` IOPLL by modifying the input clock frequency to 100 MHz.

```
adjust_pll_refclk -to {*pll_main*} -refclk 100
```

Arguments

to Instance name of upstream IOPLL that you want to adjust. Escape any [or] characters in the target name.

refclk New refclk frequency value in MHz.

7.4.6. modify_io_slew_rate

Description

Implements the I/O pin slew setting rate that you specify for the I/O pin.

Usage

```
modify_io_slew_rate 1 -to top|ipin
```

Arguments

to Instance name of destination pin that you want to modify.

7.4.7. modify_io_current_strength

Description

Implements the change to the I/O pin current strength setting that you specify for the I/O pin.

Usage

```
modify_io_current_strength 3mA -to top|ipin
```

Arguments

to Instance name of the destination pin that you want to modify.

7.4.8. modify_io_delay_chain

Description

Implements the change to the delay chain settings that you specify for the I/O pin.

Usage

```
modify_io_delay_chain 3 -to top|ipin -type input
```

Arguments

type Specifies one of the following I/O types: `input`, `output`, oe, `io_12_lane_input`, `io_12_lane_input_strobe`

to Instance name of I/O pin that you want to modify the delay chain settings.

7.4.9. create_new_node

Description

Creates a LUT cell or flip-flop in the design netlist. The following use cases apply:

- Adding a gate to fix a logic bug.
- Adding a wire LUT to help add hold delay.
- Creates a new flip-flop or flip-flops where needed.

The name of the new node is hierarchical. Therefore, when creating node a|b|c|d, you must ensure that hierarchy a|b|c exists in the netlist. If the source or destination node lies under a partition, the new LUT inserts under that partition.

Note: This command does not support extended or arithmetic LUTs.

After creating the new node, you can run the following commands to connect, modify the lutmask, or place the new node:

1. Run `make_connection` to connect to the new LUT's DATA inputs and output port.
2. Run `modify_lutmask` to change the lutmask for the new LUT.
3. Run `place_node` to place (and subsequently route) the new LUT.

This flow ensures that all routing requirements are analyzed when determining a legal placement for the new node.

Usage

The following example creates a `new_lut` LUT node with input ports DATAA and DATAB, and with outputs connected accordingly. `modify_lutmask` the modifies the lutmask to perform A&B logic. `place_node` next places the new LUT. The connections route after node placement is complete.

```
create_new_node -name new_lut -type lut
make_connection -from src_a -to new_lut -port DATAA
make_connection -from src_b -to enew_lut -port DATAB
make_connection -from new_lut -to dst_reg -port D
modify_lutmask -to new_lut -eqn A&B
place_node -name new_lut
```

To connect to a new flip-flop node that you create, use the `make_connection` command to connect to the flip-flop data port (`D`), and control ports (`CLK`, `ENA`, `SCLR`, `CLRN`), and from its output `Q` port. You must place the new flip-flop node with the `place_node` command. The connections are automatically routed after the `place_node` command.

```
create_new_node -name my_ff -type ff
make_connection -from reg0 -to my_ff -port D
make_connection -from clk -to my_ff -port CLK
make_connection -from my_ff -to reg1 -port D
place_node -name my_ff -location “X10 Y10 X10 Y10”
```

Arguments

name Name of the new LUT of flip-flop node.

7.4.10. remove_node

Description

Removes a LUT cell or flip-flop from the design netlist.

Usage

The following example deletes a flip-flop node with the name `ff1`:

```
remove_node -name ff1
```

Arguments

name Name of the LUT of flip-flop node to delete.

7.4.11. place_node

Description

Places the node that you specify in a location that the ECO Fitter selects. Optionally, you can specify the `location` argument to assign a specific device region location. You can also run this command for nodes already placed by the Fitter.

`place_node` also supports placement of newly added or existing flip-flops. `place_node` does not support Hyper-Register locations.

Usage

The following examples show three placement cases. For `node1`, the ECO Fitter determines the placement location. For `node2`, the command specifies the exact LAB location constraint. For `node3`, the command specifies a placement region constraint.

```
place_node -name node1 # let ECO Fitter decide placement
place_node -name node2 -location FF_X20_Y60_N17 # place node at specific location
place_node -name node3 -location “X10 Y10 X20 Y20” # place node in region
place_node -name my_ff -location “X10 Y10 X10 Y10” # place flip-flop in region
```

Arguments

name Name of the node.

location Device region coordinates `(X1 Y1 X10 Y10)(X1 Y1) (FF_X20_Y60_N17)`.

7.4.12. unplace_node

Description

Unplaces the node that you specify. `unplace_node` supports moving larger clouds of logic. To simplify the process of moving a larger cloud of logic, such as an entire ALM, you can first unplace all of the nodes. The Fitter does not perform placement legality checking until you re-place the final ALM cell.

Usage

The following example unplaces a node with the name `ff1`:

```
unplace_node -name ff1
```

Arguments

name Name of the node to unplace.

7.4.13. create_wirelut

Description

Creates and inserts a wire LUT node in the connection that you specify. The ECO Fitter places the new LUT and routes the modified connections automatically. Optionally, you can specify the `location` argument to specify a particular device region location constraint.

The name of the new node is hierarchical. Therefore, when creating node `a|b|c|d`, you must ensure that hierarchy `a|b|c` exists in the netlist. If the source or destination node lies under a partition, the new wire LUT inserts under that partition.

`create_wirelut` also supports adding connections from and to Hyper-Registers. In the case of Hyper-Registers, the command first disconnects the destination port, before making a new connection. You can the run the `create_wirelut` command to specify a replacement signal source or destination.

If a port is shared among multiple atoms (for example, RAM), then the ECO Fitter automatically updates all relevant atoms, and reports them accordingly.

Usage

The following example creates the `my_wirelut` wire LUT, connects `my_wirelut` output to the D input port of `dest_node`, and connects the output of `src_output` to the input port of the wire LUT. Finally, the ECO Fitter places the new node within region `(20, 20)` to `(40, 40)` and routes automatically.

```
create_wirelut -name my_wirelut -from src_output -to dest_node \
     -port D -location "X20 Y20 X40 Y40"
```

Arguments

name Name of the node.

From Source of the connection.

To Name of destination node.

Port Input port name of destination node.

location Device region coordinates `(X1 Y1 X10 Y10)` `(X1 Y1)` `(FF_X20_Y60_N17)`.

7.5. ECO Command Limitations

The ECO commands have the following limitations due to connection dependencies within Intel FPGA devices.

- You cannot use ECO commands to modify dedicated connections.
- You cannot modify dedicated connections within a single ALM. This limitation applies to direct connections between LUT and flip-flop nodes.
- You can connect from or to a Hyper-Register. However, you cannot remove connections from or to a Hyper-Register because removing a connection from a Hyper-Register would leave the routing dangling. As an alternative, you can use `make_connection` to change a Hyper-Register connection immediately, without removing the previous connection first.
- Use of the `place_node` command with `location` arguments does not overwrite Partial Reconfiguration region constraints.
- If a LAB already has the maximum number of legal connections where a node is placed, the `place_node` or `make_connection` commands can fail, preventing the connection to the first placed node that cannot be legalized. You can then either move the original node to a different location, or move other nodes from the LAB to free up routing resources.
- The Fitter may fail to apply some I/O related ECO modifications, such as `modify_io_slew_rate`, `modify_io_current_strength`, and `modify_io_delay_chain`, if called using a command-line Tcl script or in interactive context. That is, any case that calls the `eco_load_design` command directly. To ensure all I/O modifications are applied successfully, use the standard ECO Tcl script approach this document describes.

The recommended order for creating and placing new LUTs or new flipflops is:

1. Create the node by using the `create_new_node` command.
2. Make connections to and from the node by using the `make_connection` command.
3. Update the lutmask by using the `modify_lutmask` command.
4. Place the node by using the `place_node` command.

This flow ensures that analysis includes all routing requirements when determining a legal placement for the new node. For example:

Create a new LUT in an exact location

```
set lut_name new_lut
create_new_node –name $lut_name –type lut
make_connection –from input1 –to $lut_name –port DATAA
make_connection –from input2 –to $lut_name –port DATAB
make_connection –from $lut_name –to output_dest –port DATAD
modify_lutmask –to $lut_name –eqn {A&B}
place_node –name $lut_name –location “X80 Y80 X85 Y95”
```

Create a new Flipflop in an exact location

```
set ff_name new_ff
create_new_node –name $ff_name –type ff
make_connection –from input1 –to $ff_name –port DATAA
make_connection –from input2 –to $ff_name –port DATAB
make_connection –from $ff_name –to output_dest –port DATAD
modify_lutmask –to $ff_name –eqn {A&B}
place_node –name $ff_name –location “X80 Y80 X85 Y95”
```

Note: To minimize issues with name matching caused by escaped characters, it can be useful to surround entity names with {} characters, instead of "". This technique is particularly useful if entity names contain backslashes or any other special characters.

7.6. Interactive ECO Fitting

The `quartus_fit` executable supports ECO changes in an interactive shell through `quartus_fit -s`.

In an interactive context, the ECO Fitter legalizes the changes, when appropriate. For example, for `make_connection` changes immediately after node creation, the Fitter does not attempt to route the connections immediately; rather, the Fitter waits until after the placement of the node prior to routing.

7.6.1. eco_load_design and eco_commit_design Commands

Description

- `eco_load_design`—loads the final netlist in the ECO context.
- `eco_commit_design`—commits the ECO modified netlist to disk while running in interactive mode.

Usage

The following example shows an interactive ECO session to modify the `lut_x` lutmask for project `top`. If the ECO modifications are legal, the `eco_commit_design` command commits the final netlist.

```
$ quartus_fit -s
>> load_package eco
>> project_open top
>> eco_load_design
>> modify_lutmask -to lut_x -eqn B&C # some ECO changes
>> eco_commit_design
>> project_close
```

7.7. Using the ECO Compilation Flow Revision History

The following revision history applies to this chapter:

Table 46. Document Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2020.09.28	20.3	• Revised chapter title to "Using the ECO Compilation Flow." • Added descriptions of new `unplace_node` and `delete_node` commands. • Described new support for placement of flip-flop nodes and exact locations in `place_node` command topic. • Described new support for creation of flip-flop nodes in `create_new_node` command topic. • Updated limitations in "ECO Command Limitations to remove obsolete limitations." • Revised wording of introduction. • Added report screenshots to "Viewing ECO Compilation Reports" topic.
2020.05.08	20.1	• Added descriptions of new `create_new_node`, `place_node`, and `create_wirelut` commands. • Referenced support for multi-node ECOs in `make_connection`, `remove_connection`, and `create_wirelut` command topics. • Referenced Support for ECO connections to Hyper-Registers in the `make_connection` topic. • Described updates to ECO reporting in "Viewing ECO Compilation Reports." • Updated limitations in "ECO Command Limitations." • Added ECO Command Quick Reference
2019.09.30	19.3.0	• Added information about `tieoff` option for `make_connection` command. • Added support for `modify_io_slew_rate` command. • Added support for `modify_io_current_strength` command. • Added support for `modify_io_delay_chain` command. • Added "Viewing ECO Compilation Reports" topic. • Added information about `num` option for `modify_lutmask` command. • Mentioned RTL Viewer for locating node names. • Added device support note.
2019.07.01	19.2.0	• First release of chapter.

8. Quartus Prime Pro Edition Design Optimization User Guide Archives

For the latest and previous versions of this user guide, refer to Quartus Prime Pro Edition User Guide: Design Optimization. If an IP or software version is not listed, the user guide for the previous IP or software version applies.

A. Quartus Prime Pro Edition User Guides

Refer to the following user guides for comprehensive information on all phases of the Quartus Prime Pro Edition FPGA design flow.

Related Information

- Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Quartus Prime Pro Edition software, including managing Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

Quartus® Prime Pro Edition User Guide

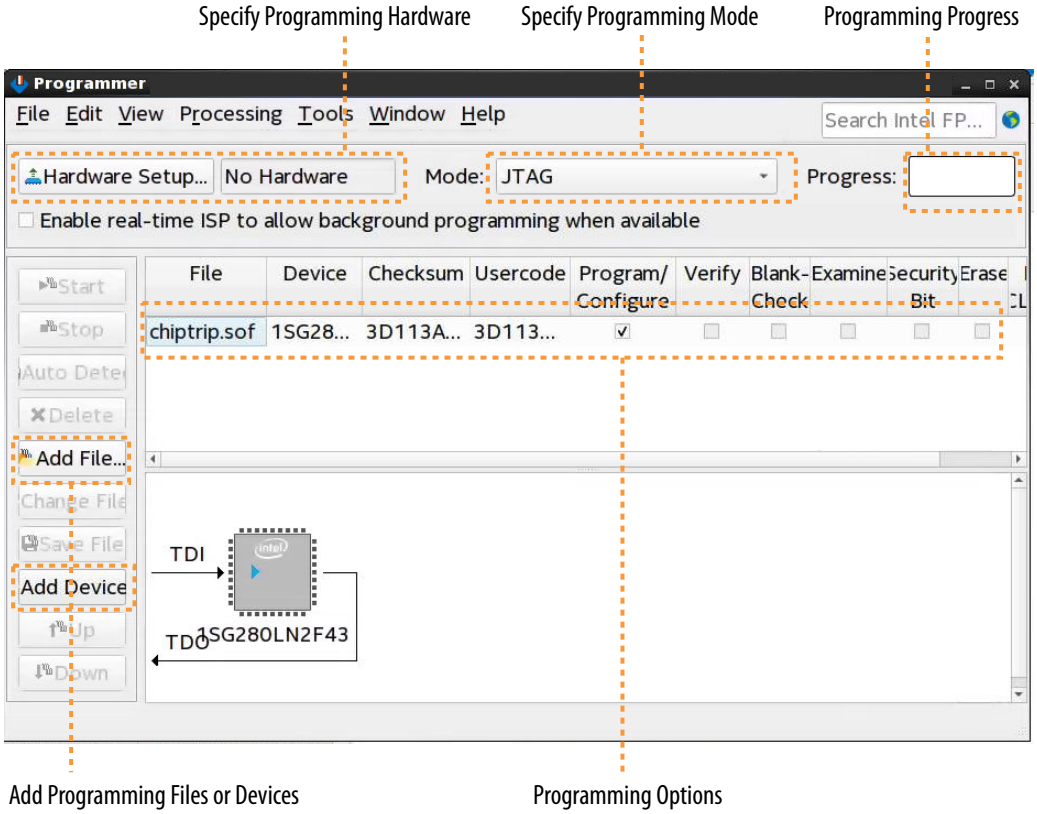
Answers to Top FAQs:

Contents

1. Quartus® Prime Programmer User Guide

The Quartus® Prime Programmer allows you to program and configure Intel® CPLD, FPGA, and configuration devices. Following full design compilation, you generate the primary device programming files in the Assembler, and then use the Programmer to load the programming file to a device. This user guide details Intel FPGA programming file generation and use of the Quartus Prime Programmer.

Figure 1. Quartus Prime Programmer



Related Information

- Generating Primary Device Programming Files on page 5
- Generating Secondary Programming Files on page 6
- Enabling Bitstream Security for Stratix 10 and Agilex 7 Devices on page 19
- Using the Quartus Prime Programmer on page 40
- Programming with Flash Loaders on page 51

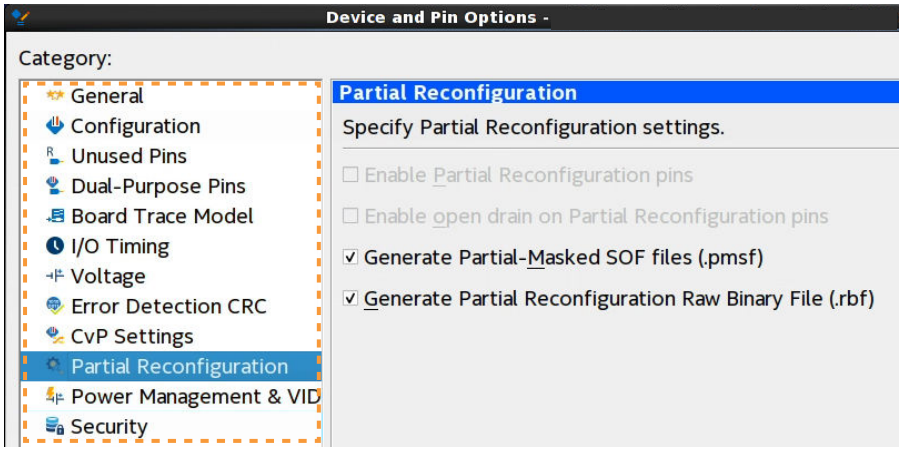
1.1. Generating Primary Device Programming Files

By default, the Compiler's Assembler module generates the primary device programming files at the end of full compilation. Alternatively, you can start the Assembler independently any time after design place and route to generate primary device programming files, such as SRAM Object Files (`.sof`) for configuration of Intel FPGAs.

Follow these steps to generate primary device programming files:

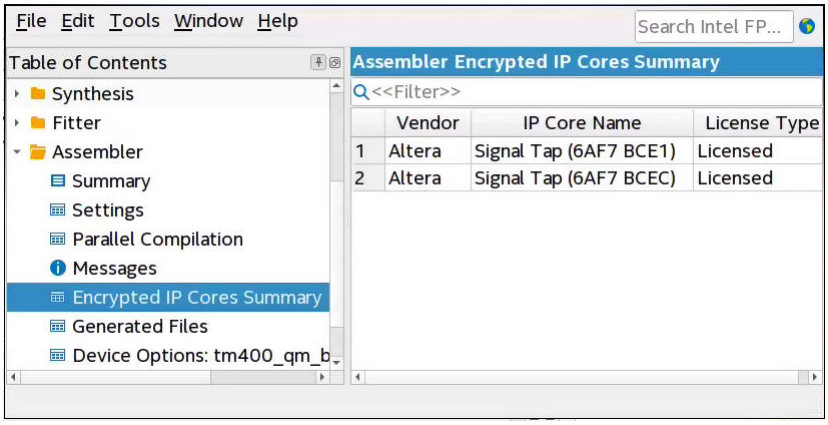
1. To specify programming options that enable features in the primary device programming file, such as **Configuration**, **Error Detection CRC**, and device **Security** options, click **Assignments ➤ Device ➤ Device & Pin Options**. Device & Pin Options Dialog Box on page 55 describes all options.

Figure 2. Device & Pin Options Dialog Box (Stratix® 10 Design)



2. To generate primary device programming files, click **Processing ➤ Start ➤ Start Assembler**, or double-click **Assembler** on the Compilation Dashboard. The Assembler generates the programming files according to the options you specify.
3. After running the Assembler, view detailed information about programming file generation, including the programming file Summary and Encrypted IP information in the Assembler report folder in the Compilation Report.

Figure 3. Assembler Reports



Note: Each successive release of the Quartus Prime software typically includes:

- Added support for new features in supported FPGA devices.
- Added support for new devices.
- Efficiency and performance improvements.
- Improvements to compilation time and resource use of the design software.

Due to these improvements, different versions of the Quartus Prime Pro Edition, Quartus Prime Standard Edition, and Quartus Prime Lite Edition software can produce different programming files from release to release.

1.2. Generating Secondary Programming Files

After generating primary device programming files, you can optionally generate one or more derivative programming files for alternative device configurations, such as flash programming, partial reconfiguration, remote system update, Configuration via Protocol (CvP), or hard processor system (HPS) core configuration.

You can use the **Programming File Generator** or **Convert Programming Files** dialog box to generate secondary programming files:

- The **Programming File Generator** supports advanced programming features and is optimized for Agilex™ 5, Agilex 7, Stratix® 10, MAX® 10, and Cyclone® 10 LP devices.
- The **Convert Programming Files** dialog box supports all devices released prior to Stratix 10 devices.

Table 1. Secondary Programming File Generators

	Programming File Generator	Convert Programming Files	
Device Support	• Agilex 5 • Agilex 7 • Stratix 10 • MAX 10 • Cyclone 10 LP	• Arria® 10 • Cyclone 10GX and LP • MAX 10	APEX20K, Arria II GX and GZ, Arria V, Cyclone, Cyclone II, Cyclone III and LS, Cyclone IV E and GX, Cyclone V, HardCopy® III, HardCopy II, HardCopy IV, MAX V, Stratix, Stratix II, Stratix III, Stratix IV, Stratix V

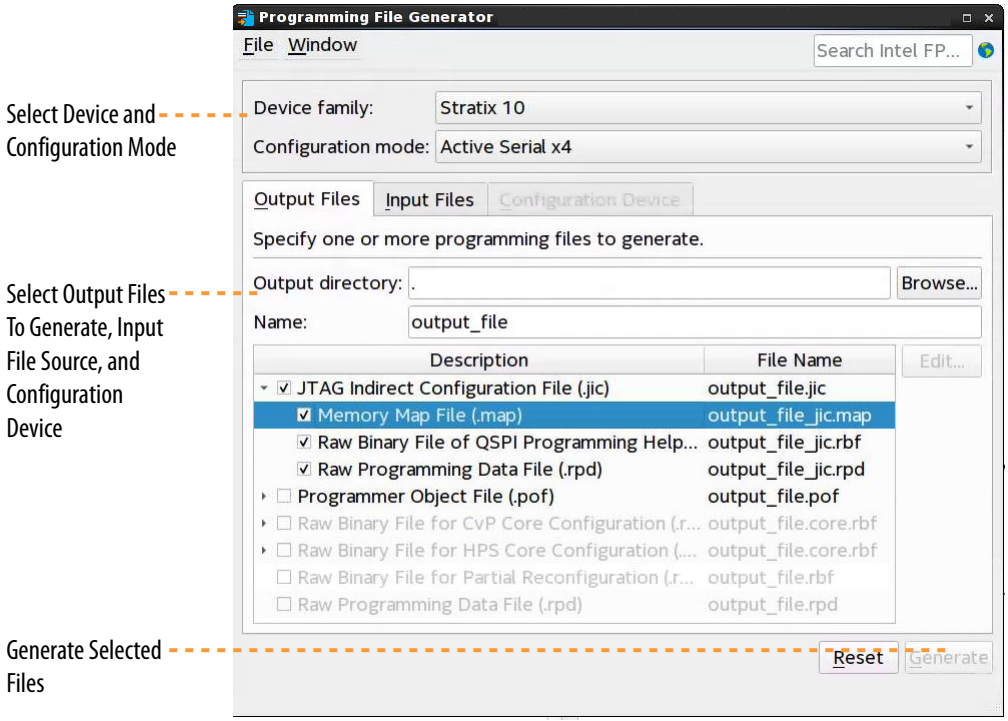
1.2.1. Generating Secondary Programming Files (Programming File Generator)

Follow these steps to generate secondary programming files for alternative device programming methods with the **Programming File Generator**.

1. Generate the primary programming files for your design, as Generating Primary Device Programming Files on page 5 describes.
2. Click **File ➤ Programming File Generator**.
3. For **Device family**, select your target device. The options available in the **Programming File Generator** change dynamically, according to your device and configuration mode selection.
4. For **Configuration mode**, select the target configuration mode for your device. Configuration Modes (Programming File Generator) on page 9 describes all modes.

5. On the **Output Files** tab, enable the checkbox for generation of the file you want to generate. The **Input Files** tab is now available. Secondary Programming Files (Programming File Generator) on page 10 describes all output files.
6. Specify the **Output directory** and **Name** for the file you generate. Output Files Tab Settings (Programming File Generator) on page 63 describes all options.

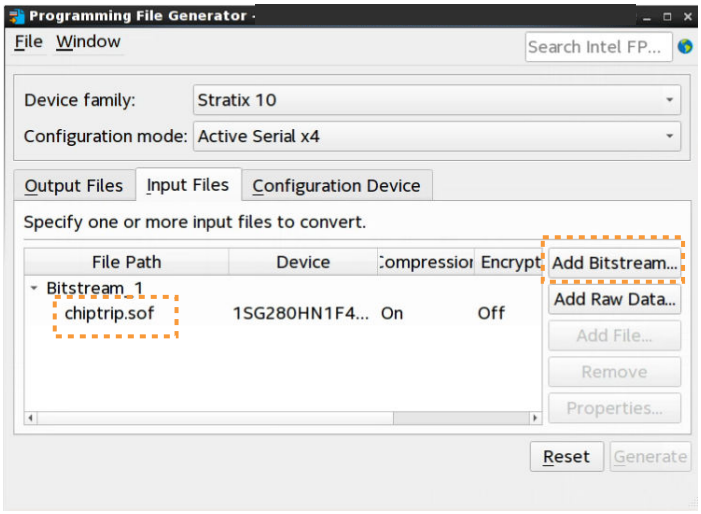
Figure 4. Programming File Generator



7. To specify a `.sof` file that contains the configuration bitstream data, on the **Input Files** tab, click **Add Bitstream**.
8. To include raw data, click **Add Raw Data** and specify a Hexadecimal (Intel-Format) file (`.hex`), Binary (`.bin`) file, or uncompressed ZIP file (`.zip`).

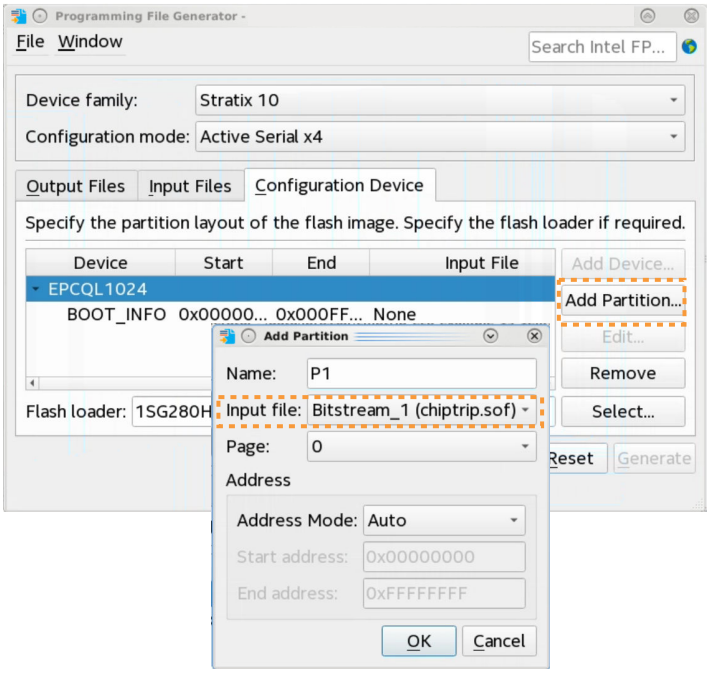
   Important: The ZIP file must be uncompressed. For example, in WinZip® file compression software, ensure that the compression mode is set to **No compression**.
9. To specify bitstream authentication or encryption security settings for the file, select the `.sof` and click **Properties**, as Enabling Bitstream Authentication (Programming File Generator) on page 20 describes.

Figure 5. Input Files Tab



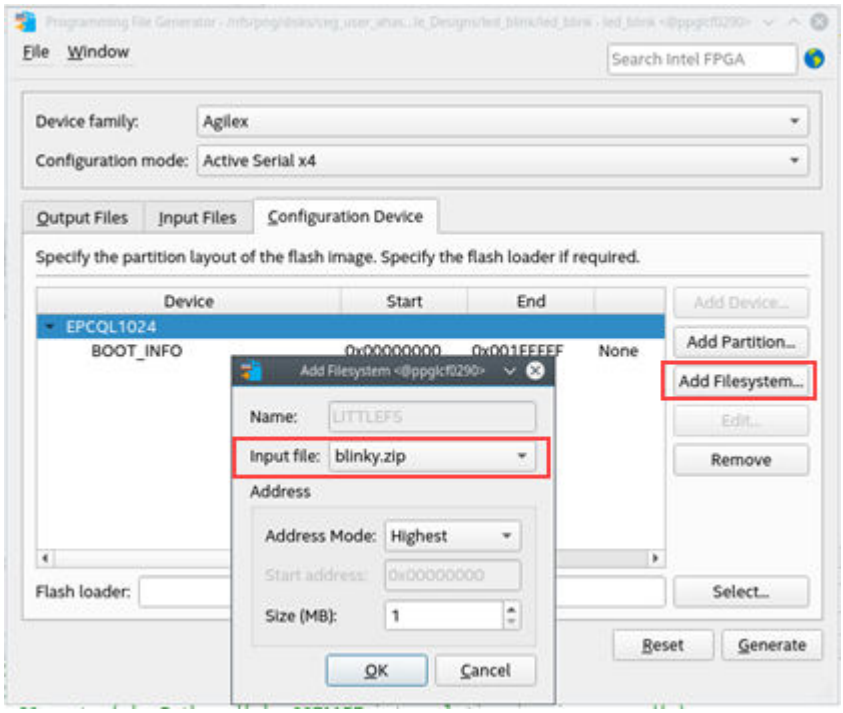
10. To create a flash memory partition and specify a `.sof` file that occupies the flash memory partition, click **Add Partition** on the **Configuration Device** tab. Add Partition Dialog Box (Programming File Generator) on page 66 describes all options.

Figure 6. Add Flash Partition



11. To create a file system partition and specify an uncompressed `.zip` file that contains the files to write to the file system partition, click **Add Filesystem** on the **Configuration Device** tab. Add Filesystem Dialog Box (Programming File Generator) on page 66 describes all options.

Figure 7. Add Flash Filesystem Partition



Important: The ZIP file must be uncompressed. For example, in WinZip file compression software, ensure that the compression mode is set to **No compression**.

12. To select a supported flash memory device and predefined programming flow, click **Add Device** on the **Configuration Device** tab. Alternatively, click **<<new device>>** to define a new flash memory device and programming flow. Configuration Device Tab Settings on page 65 describes all settings.
13. Click the **Select** button for **Flash Loader** and select the device that controls loading of the flash memory device. Select Devices (Flash Loader) Dialog Box on page 69 describes all settings.
14. After you specify all options in **Programming File Generator**, the **Generate** button enables. Click **Generate** to create the files.

1.2.1.1. Configuration Modes (Programming File Generator)

Select one of the following **Configuration modes** in **Programming File Generator** for generation of secondary programming files:

Table 2. Programming File Generator Configuration Modes

Programming Mode	Description	Supports Devices
Active Serial x4	For storing configuration data in a low-cost serial configuration device with non-volatile memory and four-pin interface. Serial configuration devices provide a serial interface to access the configuration data. During device	• Agilex 5 • Agilex 7 • Stratix 10

continued...

Programming Mode	Description	Supports Devices
	configuration, Stratix 10 devices read the configuration data through the serial interface, decompress the data if necessary, and configure their SRAM cells.	
AVST x8	The Avalon® streaming configuration mode uses an external host, such as a microprocessor or MAX 10 device. The external host controls the transfer of configuration data from an external storage such as flash memory to the FPGA. The design that controls the configuration process resides in the external host. You can use the PFL II IP core with an MAX 10 device as the host to read configuration data from a flash memory device that configures an Stratix 10 FPGA.	
AVST x16		
AVST x32		
1-Bit Passive Serial	An external controller passes configuration data to one or more FPGA devices via a serial data stream. The FPGA device is a slave device with a 5-wire interface to the external controller. The external controller can be an intelligent host such as a microcontroller or CPU.	Cyclone 10 LP
Active Serial	Stores configuration data in a low-cost serial configuration device with non-volatile memory and four-pin interface.	
Internal Configuration	Uses a `.pof` file for internal configuration of the MAX 10 device's Configuration Flash Memory (CFM) and User Flash Memory (UFM) via a download cable Quartus Prime Programmer.	MAX 10

1.2.1.2. Secondary Programming Files (Programming File Generator)

After generating primary device programming files, you can generate the following secondary device programming files with the **Programming File Generator** for alternative device configuration modes:

Table 3. Programming File Generator Output File Types

Programming File Type	Extension	Description
Hexadecimal (Intel-Format) Output File for SRAM	`.hexout`	An ASCII text file in Intel hexadecimal format that contains configuration data for programming a parallel data source, such as a configuration device or a mass storage device. The parallel data source in turn configures an SRAM-based Intel device.
JTAG Indirect Configuration File	`.jic`	Proprietary Intel FPGA file type that stores serial flash programming data for programming via Intel FPGA JTAG pins. This method only supports Active Serial configuration. Before programming the flash, the Programmer first configures the FPGA with the Serial Flash Helper Design.
Memory Map File	`.map`	A text file containing the byte addresses of pages and HEX data stored in the memory of the selected configuration device. The file stores the start and end addresses of the **Main Block Data** and **Bottom Boot Data** items, and the start and end addresses of pages within the **Main Block Data** item.
Programmer Object File	`.pof`	A binary file used by the Programmer to program a flash memory device via active serial header, or to program a flash memory device via the Parallel Flash Loader Intel FPGA IP.
Raw Binary File	`.rbf`	Configuration bitstream file for use with a third-party data source, partial reconfiguration, or HPS data source. Supports Passive Serial (PS) and Avalon-Streaming (AVST) modes.
Raw Binary File for CvP Core Configuration	`.rbf`	A binary file that containing logic that is programmed by configuration (CRAM) for CvP phase 2. The core bitstream is in `.rbf` format.

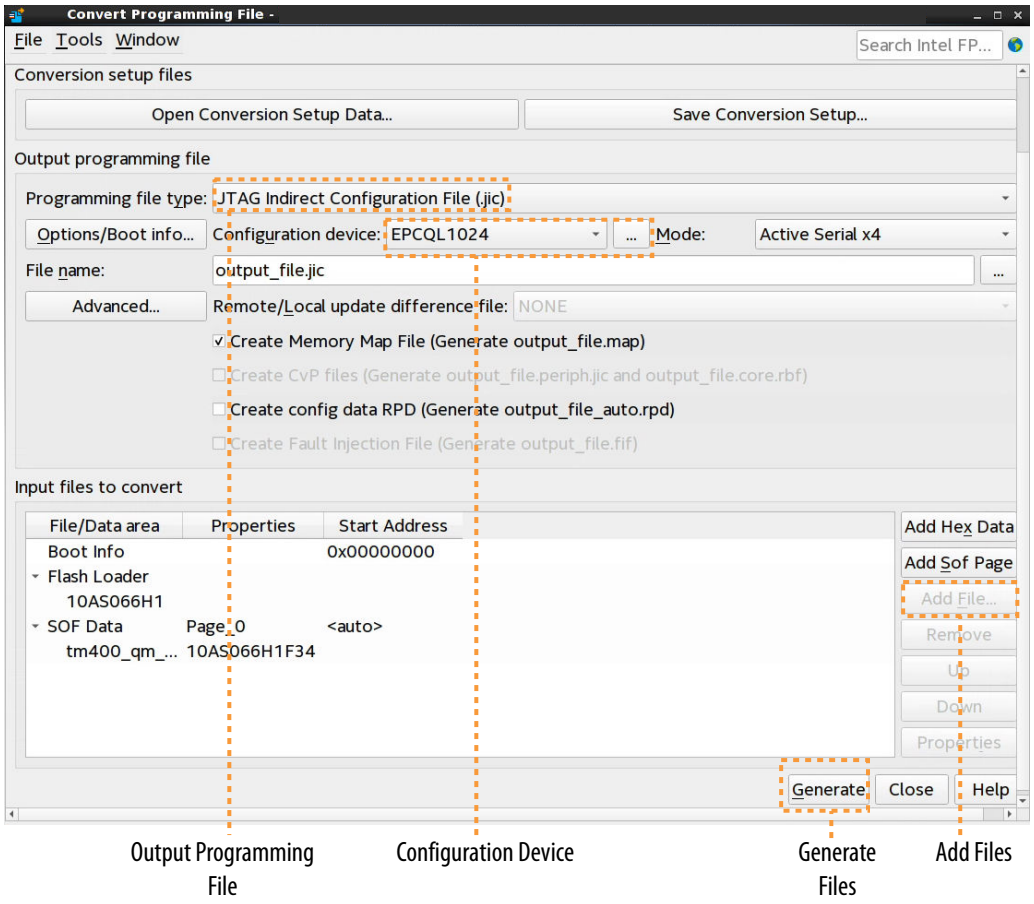
continued...

Programming File Type	Extension	Description
Raw Binary File for HPS Core Configuration	`.rbf`	A binary file that containing logic that is programmed by configuration (CRAM) for HPS configuration phase 2. The core bitstream is in `.rbf` format.
Raw Programming Data File	`.rpd`	Stores data for configuration with third-party programming hardware. You generate Raw Programming Data Files from a `.pof` or `.sof`. The `.rpd` file is a subset of a `.pof` or `.jic` that includes only device-specific binary programming data for Active Serial configuration scheme with EPCS or EPCQ serial configuration devices and remote system update.
Tabular Text File	`.ttf`	A TTF contains the decimal equivalent of a Raw Binary File (.rbf).

1.2.2. Generating Secondary Programming Files (Convert Programming File Dialog Box)

You can use the **Convert Programming File** dialog box to generate secondary programming files for alternative device programming methods. For example, generating the `.jic` file for flash programming, the `.rbf` file for partial reconfiguration, or the `.rpd` file for a third-party programmer configuration.

Figure 8. Convert Programming File Dialog Box

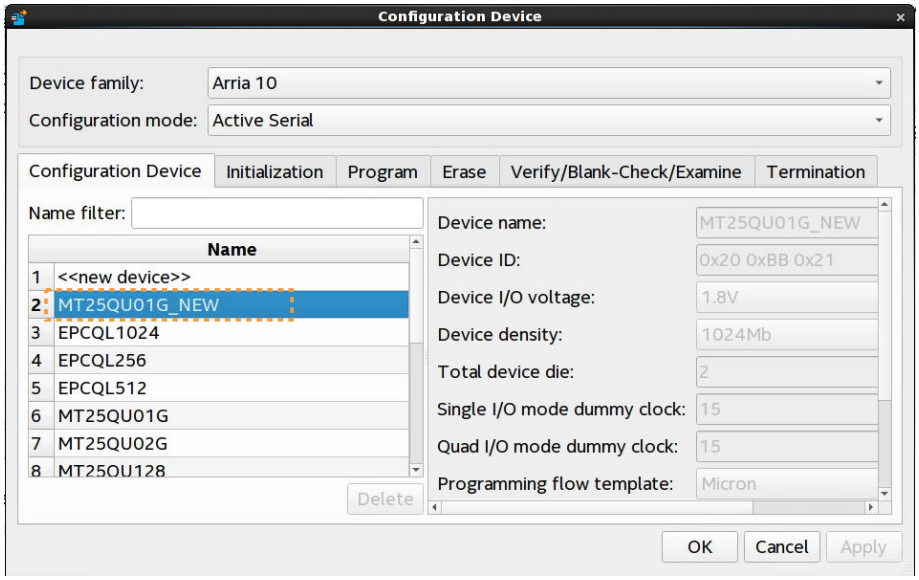


The options available in the **Convert Programming File** dialog box change dynamically, according to your device and configuration mode selection.

1. Generate the primary programming files for your design, as Generating Primary Device Programming Files on page 5 describes.
2. Click **File ➤ Convert Programming Files**.
3. Under **Output programming file**, select the **Programming file type** that you want to generate. Secondary Programming Files (Convert Programming Files) on page 13 describes all file options.
4. Specify the **File name** and output directory **(...)** for the file that you generate.
5. For the configuration **Mode**, select **Active Serial x4** or **Active Serial**. Configuration Modes (Convert Programming Files) on page 14 describes all modes.

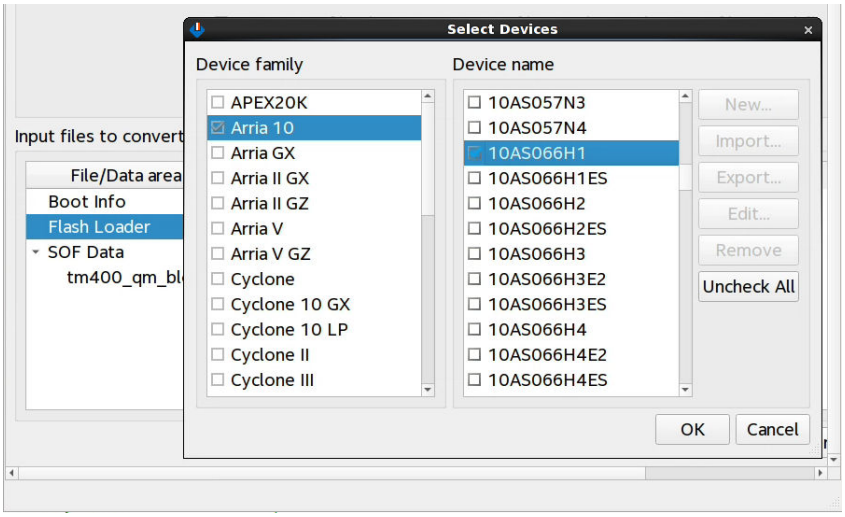
   Note: Stratix 10 devices support only **Active Serial x4**.
6. To specify the **Configuration device**, click the **(...)** button to select a supported flash memory device and predefined programming flow. When you select a predefined device, you cannot modify any setting. Alternatively, click **<<new device>>** to define a new flash memory device and programming flow. Configuration Device Tab Settings on page 65 describes all settings.

Figure 9. Configuration Device Dialog Box



7. Under **Input files to convert**, select the **SOF Data** item, and then click the **Add File** button. Specify the `.sof` file that contains the configuration bitstream data. To include raw data, click **Add Hex Data** and specify a `.hex` file.
8. To enable bitstream compression or encryption security settings, select the `.sof` file and click **Properties**, as Enabling Bitstream Encryption or Compression for Arria 10 and Cyclone 10 GX Devices on page 24 describes.
9. Select the **Flash Loader** text, and then click the **Add Device** button. Select the device that controls loading of the flash device.

Figure 10. Selecting the Flash Loader Device



10. After you specify all options in the **Convert Programming File** dialog box, click the **Generate** button to create the files.

1.2.2.1. Secondary Programming Files (Convert Programming Files)

After generating primary device programming files, you can generate the following secondary device programming files with the **Convert Programming Files** dialog box for alternative device configuration modes:

Table 4. Output File Types

Programming File Type	Extension	Description
CvP Files	`.jic/.rbf`	Files required for CvP configuration.
Hexadecimal (Intel-Format) Output File for SRAM	`.hexout`	An ASCII text file in Intel hexadecimal format that contains configuration data for programming a parallel data source, such as a configuration device or a mass storage device. The parallel data source in turn configures an SRAM-based Intel device.
JTAG Indirect Configuration File	`.jic`	Proprietary Intel FPGA file type that stores serial flash programming data for programming via Intel FPGA JTAG pins. This method only supports Active Serial configuration. Before programming the flash, the Programmer first configures the FPGA with the Serial Flash Helper Design.
Memory Map File	`.map`	Contains the byte addresses of pages and HEX data stored in the memory of the selected configuration device. The Map File stores the start and end addresses of the **Main Block Data** and **Bottom Boot Data** items, and the start and end addresses of pages within the **Main Block Data** item.
Partial-Masked SRAM Object Files	`.pmsf`	Contains the partial-mask bits for configuration of a PR region. The `.pmsf` file contains all the information for creating PR bitstreams.
Merged Mask Setting File	`.msf`	Contains the mask bits for the static region in a PR design.
Programmer Object File	`.pof`	A binary file that contains the data for programming non-volatile MAX 10, MAX V, MAX II, or flash memory devices that can configure Intel FPGA devices. A Programmer consists of a remote update

continued...

Programming File Type	Extension	Description
		enabled `.pof` and additional remote update enabled `.sof` that you used to program configuration devices in remote update configuration mode.
Raw Binary File	`.rbf`	Configuration bitstream file for use with a third-party data source, partial reconfiguration, or HPS data source. Supports Passive Serial (PS) and Avalon-Streaming (AVST) modes.
Raw Programming Data File	`.rpd`	Stores data for configuration with third-party programming hardware. You generate Raw Programming Data Files from a `.pof` or `.sof`. The `.rpd` file is a subset of a `.pof` or `.sof` that includes only device-specific binary programming data for Active Serial configuration scheme with EPCS or EPCQ serial configuration devices and remote system update. The `.rpd` file content has one bit swapped in comparison with the output file.
Tabular Text File	`.ttf`	A TTF contains the decimal equivalent of a Raw Binary File (.rbf).

1.2.2.2. Configuration Modes (Convert Programming Files)

Select one of the following **Configuration modes** in **Convert Programming Files** for generation of secondary programming files:

Table 5. Convert Programming Files Configuration Modes

Programming Mode	Description
1-Bit/2-Bit/4-Bit/8-Bit Passive Serial	An external controller passes configuration data to one or more FPGA devices via a serial data stream. The FPGA device is a slave device with a 5-wire interface to the external controller. The external controller can be an intelligent host such as a microcontroller or CPU, or the Quartus Prime Programmer, or an EPC2 or EPC16 configuration device.
Active Parallel	Supports configuration devices using commodity 16-bit parallel flash memories to control the configuration interface.
Active Serial	For storing configuration data in a low-cost serial configuration device with non-volatile memory. Serial configuration devices provide a serial interface to access the configuration data. During device configuration, the device reads the configuration data through the serial interface, decompresses the data if necessary, and configures their SRAM cells.
Active Serial x4	
AVST x8/x16/x32	The Avalon streaming configuration mode uses an external host, such as a microprocessor or MAX 10 device. The external host controls the transfer of configuration data from an external storage such as flash memory to the FPGA. The design that controls the configuration process resides in the external host. You can use the PFL II IP core with an MAX 10 device as the host to read configuration data from a flash memory device that configures an FPGA.
Passive Parallel Synchronous	An external controller, such as a CPU, loads the design data into a device via a common data bus. Data is latched by the device on the first rising edge of a CPU-driven clock signal. The next eight falling clock edges serialize this latched data within the device. The device latches the next 8-bit byte of data on every eighth rising edge of the clock signal until the device is completely configured.
Passive Parallel Asynchronous	An external controller, such as a CPU, loads the design data into a device via a common data bus. The device accepts a parallel byte of input data. Intelligent communication between the external controller and the device allows the external controller to configure the device.
Internal Configuration	Uses a `.pof` file for internal configuration of the MAX 10 device's Configuration Flash Memory (CFM) and User Flash Memory (UFM) via a download cable Quartus Prime Programmer.

1.2.2.3. Debugging the Configuration (Convert Programming Files)

Click the **Advanced** option in the **Convert Programming Files** dialog box to debug the file conversion configuration. Only choose advanced settings that apply to the design's target Intel FPGA device.

Changes in the **Advanced Options** dialog box affect `.pof`, `.jic`, `.rpd`, and `.rbf` file generation.

The following table describes the **Advanced Options** settings:

Table 6. Advanced Options Settings

Option Setting	Description	Values
Disable EPCS/EPCQ ID check	Directs the FPGA to skips the EPCS/EPCQ silicon ID verification. Applies to single and multi device AS configuration modes on all devices.	Default setting is ON (EPCS/EPCQ ID check is enabled).
Disable AS mode CONF_DONE error check	Directs the FPGA to skip the CONF_DONE error check. Applies to single- and multi-device (AS) configuration modes on all devices.	Default setting is OFF (AS mode CONF_DONE error check is enabled).
Program Length Count adjustment	Specifies the offset you can apply to the computed PLC of the entire bitstream. Applies to single- and multi-device (AS) configuration modes on all FPGA devices.	Integer (Default = 0)
Post-chain bitstream pad bytes	Specifies the number of pad bytes appended to the end of an entire bitstream.	If the bitstream of the last device is uncompressed, default value is 0. Otherwise, default is 2
Post-device bitstream pad bytes	Specifies the number of pad bytes appended to the end of the bitstream of a device. Applies to all single-device configuration modes on all FPGA devices.	Zero or positive integer. Default is 0
Bitslice Padding Value	Specifies the padding value used to prepare bitslice configuration bitstreams, such that all bitslice configuration chains simultaneously receive their final configuration data bit. Use only in 2, 4, and 8-bit PS configuration mode, when you use an EPC device with the decompression feature enabled. Applies to all FPGA devices that support enhanced configuration devices.	0 or 1 Default value is 1

The following table lists possible symptoms of a failing configuration, and describes the advanced options necessary for configuration debugging.

Failure Symptoms	Disable EPCS/ EPCQ ID Check	Disable AS Mode CONF_DONE Error Check	PLC Settings	Post-Chain Bitstream Pad Bytes	Post-Device Bitstream Pad Bytes	Bitslice Padding Value
Configuration failure occurs after a configuration cycle.	—	Yes	Yes	Yes (1)	Yes (2)	—
Decompression feature is enabled.	—	Yes	Yes	Yes (1)	Yes (2)	—
Encryption feature is enabled.	—	Yes	Yes	Yes (1)	Yes (2)	—
CONF_DONE stays low after a configuration cycle.	—	Yes	Yes (3)	Yes (1)	Yes (2)	—
CONF_DONE goes high momentarily after a configuration cycle.	—	Yes	Yes (4)	—	—	—
FPGA does not enter user mode even though CONF_DONE goes high.	—	—	—	Yes (1)	Yes (2)	—
Configuration failure occurs at the beginning of a configuration cycle.	Yes	—	—	—	—	—
EPCS128	Yes	—	—	—	—	—
Failure in .pof generation for EPC device using Quartus Prime Convert Programming File Utility when the decompression feature is enabled.	—	—	—	—	—	Yes

1.2.3. Generating Secondary Programming Files (Settings: Programming Files Dialog Box)

Follow these steps to generate .rbf files automatically as part of a standard compilation from the Quartus Prime GUI.

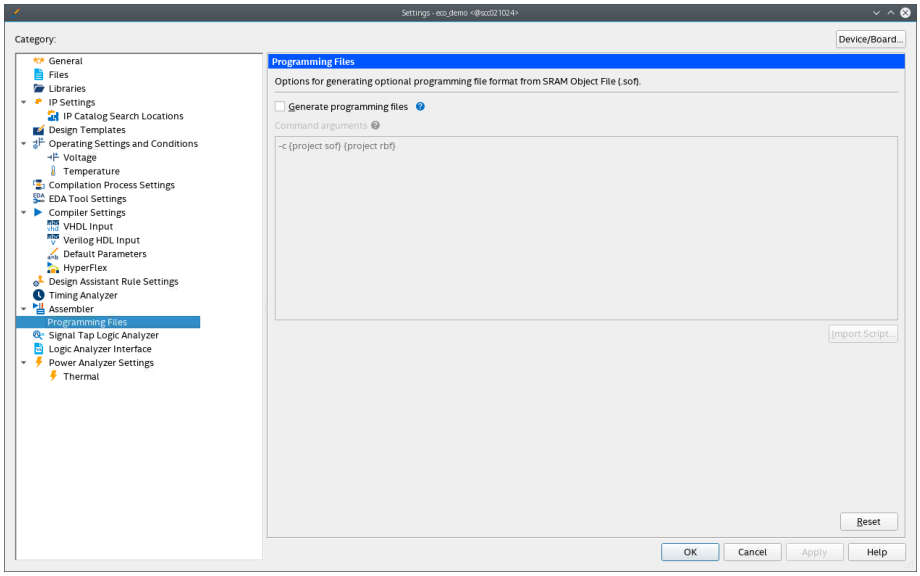
1. In Quartus Prime, select **Assignments ➤ Settings**.
2. In the **Settings** window, select **Assembler ➤ Programming Files**.

(1) Use only for multi-device chain

(2) Use only for single-device chain

(3) Start with positive offset to the PLC settings

(4) Start with negative offset to the PLC settings



3. In the **Programming Files** pane, select **Generate programming files**.

   Selecting this check box enables the default command arguments `-c .sof .rbf`.

4. (Optional) To override the default command arguments, enter your command in the **Command arguments** box or click **Import Script** to upload a script file.

   If the **Command arguments** box is not empty, only the command arguments in this box are run. The default command arguments are not run.

   Each argument line the **Command arguments** box is subject to the following conditions:

   - Lines must each begin with `-c` or `--convert`.
   - Lines must each contain at least two argument tokens.
   - Lines cannot contain pipes. For lines that contain pipes, only the first command argument before the first pipe in the command argument is executed.

   For example, `-c <project_name>.sof <project_name>.rbf`.

   If an argument line does not meet these conditions, you might see one of the following errors:

Figure 11. Error message when command argument lines do not begin with -c or --convert

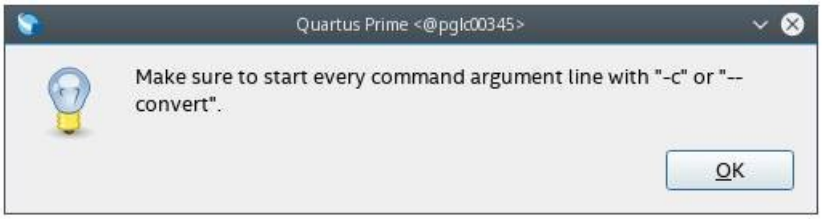


Figure 12. Error message when command argument line does not contain at least two arguments

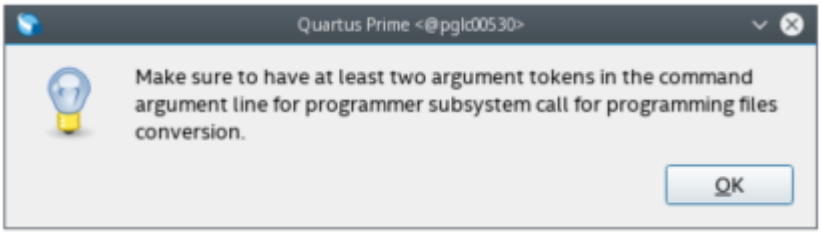

Figure 13. Error message when command argument line contains a pipe

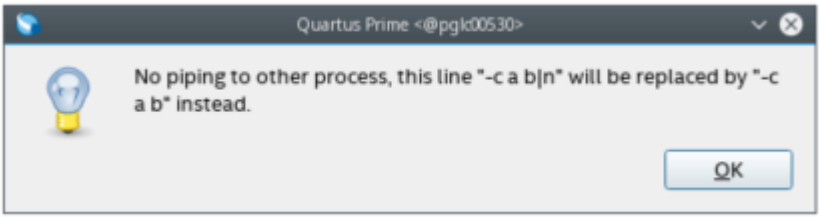

5. Click **Apply** then click **OK**.

Ensure that the path to the `.sof` file is correct, otherwise you receive error messages similar to the following messages:

```
Error(22528): Programming files generation using command Error (19509):
Cannot locate file output_files/abc.sof. was unsuccessful. Check pfg.log for more
info.
```

A `pfg_commands.txt` file is generated and the QSF file is updated with the following settings:

```
GENERATE_PROGRAMMING_FILES=ON
CONVERT_PROGRAMMING_FILES_COMMANDS /<user-project-path>/pfg_commands.txt
```

1.3. Enabling Bitstream Security for Stratix 10 and Agilex 7 Devices

Stratix 10 and Agilex 7 devices provide flexible and robust security features to protect sensitive data, intellectual property, and device hardware from physical and remote attacks. The Stratix 10 and Agilex 7 device architectures support bitstream authentication and encryption security features. The Assembler applies bitstream compression automatically to reduce file size whenever you use authentication or encryption.

- **Bitstream Authentication**—verifies that the configuration bitstream and firmware are from a trusted source. Enable additional co-signing device firmware authentication to ensure that only signed firmware runs on the HPS or FPGA, and to authorize HPS JTAG debugging. Enable authentication security by specifying a first level signature chain file (`.qky`) for the **Quartus Key File** option (**Device and Pin Options** dialog box), as Enabling Bitstream Authentication (Programming File Generator) on page 20 describes.(5)
- **Bitstream Encryption**—protects proprietary or sensitive data from view or extraction in the configuration bitstream using an Advanced Encryption Standard (AES) 256-bit or 384-bit security key. Encryption also provides side-channel protection from non-intrusive attack. You can store the owner AES key in eFuses or BBRAM. Enable encryption by turning on the **Enable programming bitstream encryption** option (**Device and Pin Options** dialog box), as Enabling Bitstream Encryption (Programming File Generator) on page 23 describes.

Table 7. Stratix 10 and Agilex 7 Bitstream Authentication Files

Term	Description	Extension
First Level Signature Chain Key File	File you generate that specifies the root key (`.pem`) and one or more design signing keys (`.pem`) required to sign the bitstream and allow access to the FPGA when using authentication or encryption.	`.qky`
Root Key File	File you generate that anchors the first level signature chain to a known root key. The FPGA calculates the hash of the root entry and checks if it matches the expected hash. The Assembler appends the root key to the programming file and stores the key in eFuses.	`.qky`
Design Signing Key File	File you generate and append to the root key that authenticates the bitstream in the SDM to allow configuration of the device with the pending bitstream. Use separate design signing keys for the FPGA and HPS for highest security.	`.pem`
Firmware Co-signing Key File	Files provided in `<install>\devices\programmer\firmware` that includes the owner signature and firmware file that you use to sign the firmware to run on the FPGA or HPS.	`.zip`
Signed HPS Certificate File	Specifies a secure HPS debug certificate that permits access to the JTAG interface for HPS debugging. A secure HPS debug certificate is valid until you power down or reconfigure the device.	`.cert`

Note: Arria 10 and Cyclone 10 GX devices do not support bitstream authentication.

Related Information

  For detailed information on generating device security keys.

(5) For Stratix 10 devices, bitstream authentication is available only for devices that include the AS (Advanced Security) ordering code suffix and all Stratix 10 DX devices.

- Agilex 7 Device Security User Guide
  For detailed information on generating device security keys.

1.3.1. Enabling Bitstream Authentication (Programming File Generator)

Bitstream authentication requires that you generate a first level signature chain (`.qky`) that includes the root key and one or more design signing keys. The root key enables the base security features and authenticates the design signing key through the public signature chain. The root key stores the SHA-256 or SHA-384 hash of the key in eFuses.

You can also optionally enable firmware co-signature capability to require signing the version of configuration firmware that runs on your device. The FPGA device then can load only authenticated firmware.

Note: For step-by-step first level signature chain key generation instructions, refer to one of the following guides:

- *Stratix 10 Device Security User Guide*
- *Agilex 7 Device Security User Guide*

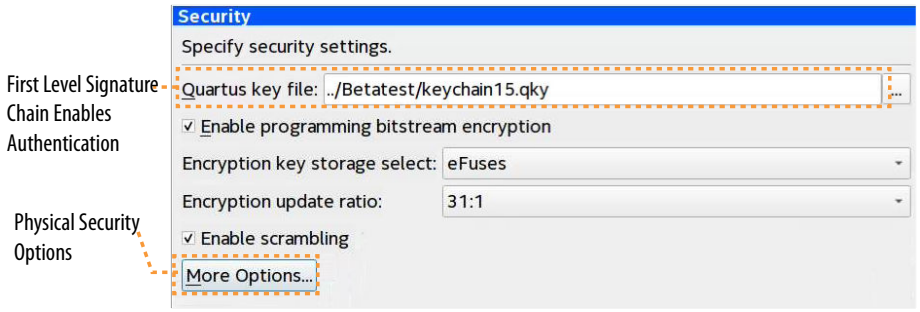
After you specify the `.qky` in Assembler settings, the Assembler appends the first level signature chain to the configuration `.sof` that you generate.

Use the **Programming File Generator** to generate the signed configuration bitstream for an `.sof` file. The JTAG Indirect Configuration File (`.jic`) and Raw Programming Data File (`.rpd`) formats are available for Active Serial (AS) configuration. The Programmer Object File (`.pof`) and Raw Binary File (`.rbf`) are available for Avalon Streaming configuration.

Follow these steps to enable bitstream authentication:

1. Generate a first level signature chain (`.qky`) that includes the root key and one or more design signing keys, as *Stratix 10 Device Security User Guide* and *Agilex 7 Device Security User Guide* describe.
2. To add the first level signature chain to a configuration bitstream, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Security**, and then specify the first level signature chain `.qky` for the **Quartus key file** option.
3. To enable more physical device security options, click the **More Options** button on the **Security** page. More Security Options Dialog Box on page 63 describes all options.

Figure 14. Security Tab (Device and Pin Options)



4. Generate primary device programing files in the Assembler, as Generating Primary Device Programming Files on page 5 describes. The primary device programming file now contains data to enable first level authentication.
5. To optionally enable co-signing device firmware authentication, generate a `.jic` or `.rbf` secondary programming file with the following options, as Generating Secondary Programming Files on page 6 describes:
   a. In **Programming File Generator**, click the **Properties** button. The **Input File Properties** dialog box appears.

Figure 15. Enabling Co-Signing Device Firmware Authentication (Stratix 10 Devices)

   b. Set **Enable signing tool** to **On**.
   c. For **Private key file**, specify a design signing key Privacy Enhanced Mail Certificates file (`.pem`) for firmware co-signing. This key can be separate from the FPGA design signing key.
   d. For **Co-signed firmware**, specify a Quartus Co-Signed Firmware file (`.zip`).
   e. Click **OK**.
6. Use the Programmer to configure the device with the `.jic` or `.rbf`.

Related Information

- Device & Pin Options Dialog Box on page 55
- Specifying Additional Physical Security Settings (Programming File Generator) on page 22
- Stratix 10 Device Security User Guide
  For detailed information on generating device security keys.
- Agilex 7 Device Security User Guide
  For detailed information on generating device security keys.

1.3.2. Specifying Additional Physical Security Settings (Programming File Generator)

Stratix 10 and Agilex 7 devices can store security and other configuration settings in eFuses. You can enable additional physical security settings in eFuses to extend the level of device security protection.

To specify additional physical device security settings, follow these steps:

1. Click **Assignments ➤ Device ➤ Device and Pin Options ➤ Security**.
2. On the **Security** tab, specify the First Level Signature Chain `.qky` file that contains the root key and one or more design signing keys for the **Quartus key file** setting.
3. Click the **More Options** button and specify any of the following:

Figure 16. More Security Options Dialog Box

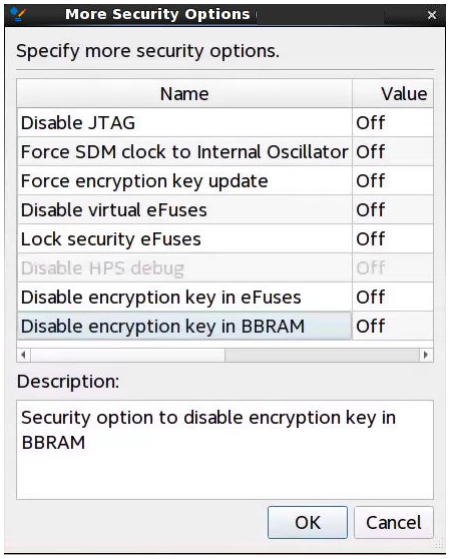


Table 8. More Security Options Dialog Box Settings

Option	Description	Values
Disable JTAG	Disables JTAG command and configuration of the device. Setting this eliminates JTAG as mode of attack, but also eliminates boundary scan functionality.	• **Off**—inactive • **On**—active until wipe of containing design • **On sticky**—active until next POR • **On check**—checks for corresponding blown fuse
Force SDM clock to internal oscillator	Disables an external clock source for the SDM. The SDM must use the internal oscillator. Using an internal oscillator is more secure than allowing an external clock source for configuration.	
Force encryption key update	Specifies that the encryption key must update by the frequency that you specify for the **Encryption update ratio** option. The default ration value is 31:1. Encryption supports up to 20 intermediate keys.	
Disable virtual eFuses	Disables the eFuse virtual programming capability.	
Lock security eFuses	Causes eFuse failure if the eFuse CRC does not match the calculated value.	

continued...

Option	Description	Values
Disable HPS debug	Disables debugging through the JTAG interface to access the HPS.	
Disable encryption key in eFuses	Specifies that the device cannot use an AES key stored in eFuses. Rather, you can provide an extra level of security by storing the AES key in BBRAM.	
Disable encryption key in BBRAM	Specifies that the device cannot use AES key stored in BBRAM. Rather, you can provide an extra level of security when you store the AES key in eFuses.	

4. Click **OK**.

Related Information

Enabling Bitstream Authentication (Programming File Generator) on page 20

1.3.3. Enabling Bitstream Encryption (Programming File Generator)

To enable bitstream encryption, you must first generate a first level signature chain (`.qky`) that enables encryption options in the GUI. Next, you generate the encrypted configuration bitstream in the Assembler. Finally, you generate a secondary programming file that specifies the AES **Encryption Key file** (`.qek`) for bitstream decryption.

Follow these steps to enable bitstream encryption:

1. Generate a First Level Signature Chain that includes the root key and one or more design signing keys, as *Stratix 10 Device Security User Guide* and *Agilex 7 Device Security User Guide* describe.
2. Click **Assignments ➤ Device ➤ Device and Pin Options ➤ Security**.
3. For the **Quartus key file** setting, specify the first level signature chain `.qky` that contains the root key and one or more design signing keys.
4. Turn on **Enable programming bitstream encryption**, and specify one or more of the following:

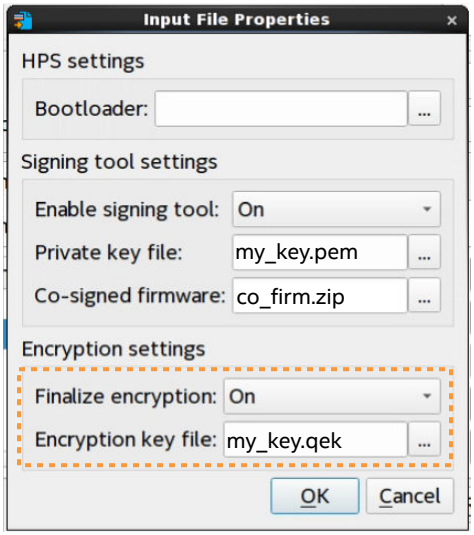
Table 9. Assembler Encryption Security Settings

Option	Description
Encryption key storage select	Specifies the location that stores the `.qek` key file. You can select either **Battery Backup RAM** or **eFuses** for storage.
Encryption update ratio	Specifies the ratio of configuration bits compared to the number of key updates required for bitstream decryption. You can select either **31:1** (the key must change 1 time every 31 bits) or **Disabled** (no update required). Encryption supports up to 20 intermediate keys.
Enable scrambling	Scrambles the configuration bitstream.
More Options	Opens the **More Security Options** dialog box for specifying additional physical security options.

5. Generate primary device programing files in the Assembler, as Generating Primary Device Programming Files on page 5 describes.
6. Generate a `.jic` or `.rbf` secondary programming file, as Generating Secondary Programming Files on page 6 describes:
   a. In the **Programming File Generator**, select the `.sof` file on the **Input Files** tab.

b. Click the **Properties** button. The **Input File Properties** dialog box appears.

Figure 17. Input File Properties



c. Set **Finalize encryption** to **On**.

d. Specify the AES 256-bit or 384-bit **Encryption key file** (`.qek`) to decrypt the bitstream in the SDM prior to device configuration.

7. Click **OK**.

Related Information

Input Files Tab Settings (Programming File Generator) on page 64

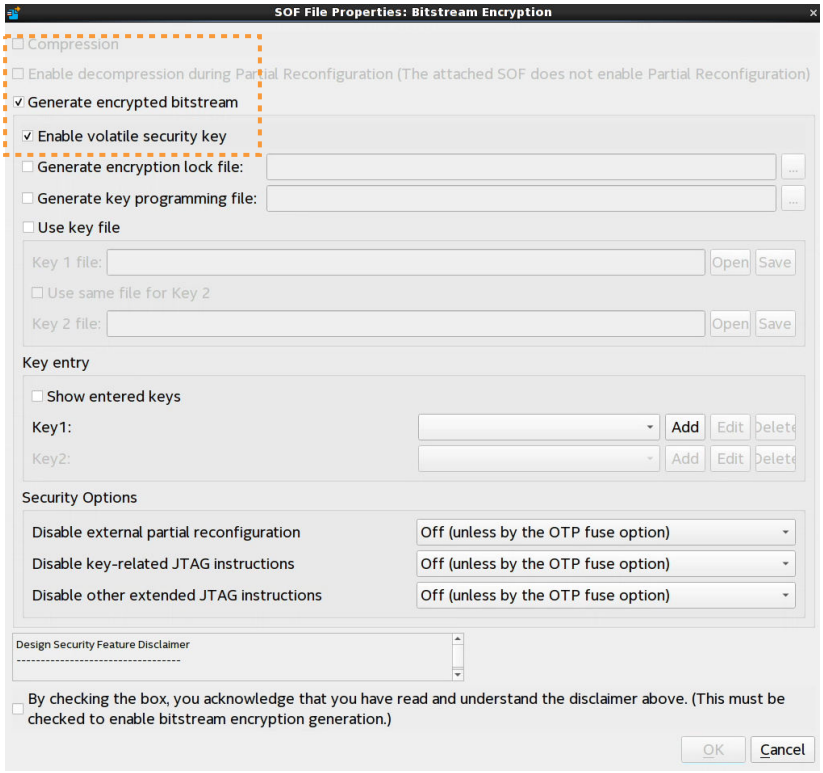
1.4. Enabling Bitstream Encryption or Compression for Arria 10 and Cyclone 10 GX Devices

You can optionally enable bitstream file encryption that requires a user-defined 256-bit security key to access the configuration bitstream. Alternatively, you can enable bitstream compression to reduces the size of your programming file to minimize file transfer and storage requirements. The compression reduces configuration file size by 30% to 55% (depending on the design). File compression and encryption options are mutually exclusive for Arria 10 and Cyclone 10 GX devices.

Follow these steps to enable bitstream file compression or encryption for Arria 10 and Cyclone 10 GX devices:

1. Generate a `.jic` file for flash programming, as this document describes.
2. In the **Convert Programming File** dialog box, select the `.sof` file under **Input files to convert**.
3. Click the **Properties** button. The **SOF File Properties: Bitstream Encryption** dialog box appears.

Figure 18. Enabling Bitstream Compression or Encryption (Intel Arria 10 and Intel Cyclone 10 GX Designs)



4. To enable compression, turn on the **Compression** option. All encryption options disable as these options are mutually exclusive.
5. To enable bitstream file encryption:
   a. Turn off the **Compression** option.
   b. Turn on the **Generate encrypted bitstream** option.
   c. Specify options for programming file key decryption, and **Security Options**, as Compression and Encryption Settings (Convert Programming File) on page 67 describes.
6. Click **OK**.

1.5. Generating Programming Files for Partial Reconfiguration

The following sections describe generation of bitstream and other files for partial reconfiguration.

1.5.1. Generating PR Bitstream Files

For Agilex 7, Agilex 5, and Stratix 10 designs, the Assembler generates a configuration `.rbf` automatically at the end of compilation. For Arria 10 and Cyclone 10 GX designs, use any of the following methods to process the PR bitstreams and generate the Raw Binary File (`.rbf`) file for reconfiguration.

Generating PR Bitstreams During Compilation

Follow these steps to generate the `.rbf` file during compilation for Arria 10 and Cyclone 10 GX designs:

1. Add the following assignments to the revision `.qsf` to automatically generate the required PR bitstreams following compilation:

```
set_global_assignment -name GENERATE_PR_RBF_FILE ON
set_global_assignment -name ON_CHIP_BITSTREAM_DECOMPRESSION OFF
```

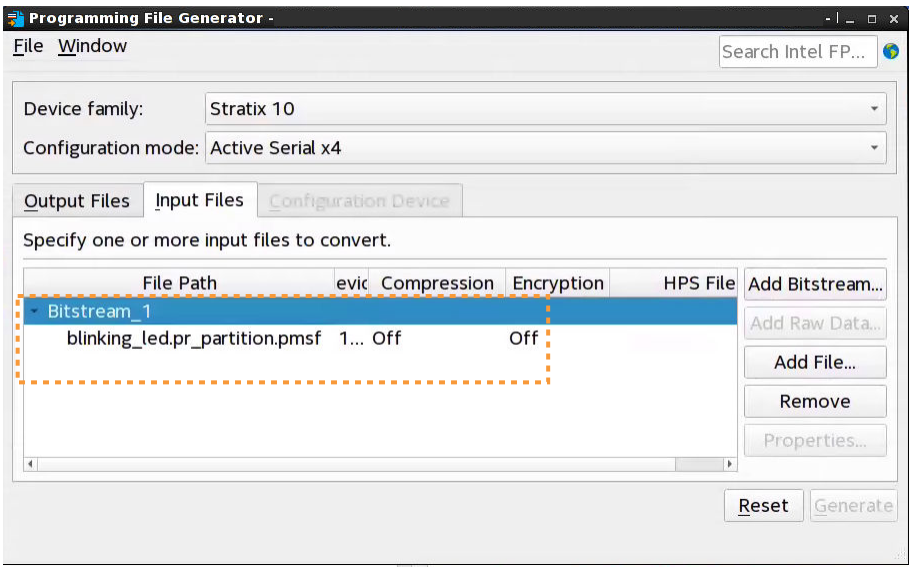
2. To compile the revision and generate the `.rbf`, click **Processing ➤ Start Compilation**.

Generating PR Bitstreams with Programming File Generator

Follow these steps to generate the `.rbf` for PR programming with the **Programming File Generator**:

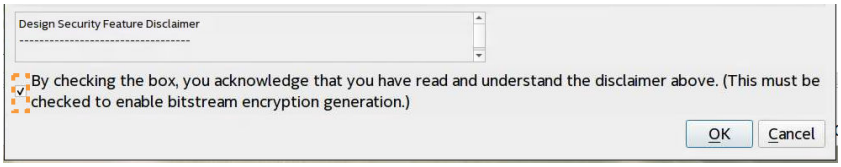
1. Click **File ➤ Programming File Generator**. The **Programming File Generator** appears.
2. Specify the target **Device family** and the **Configuration mode** for partial reconfiguration.
3. On the **Output File** tab, specify the **Output directory**, file **name**, and enable the **Raw Binary File for Partial Reconfiguration (.rbf)** file type.
4. To add the input `.pmsf` file to convert, click the **Input Files** tab, click **Add Bitstream**, and specify the `.pmsf` that you generated in the Assembler.

Figure 19. Adding Bitstream File



5. On the **Input Files** tab, select the bitstream `.pmsf` file and click **Properties**. Specify any of the following options for the `.rbf`:
   - **Enable compression**—generates compressed PR bitstream files to reduce file size.
   - **Enable encryption**—generates encrypted independent bitstreams for base image and PR image. You can encrypt the PR image even if your base image has no encryption. The PR image can have a separate encryption key file (`.ekp`). You can also specify other **Security settings**.
   - If you turn on **Enable encryption**, you must also acknowledge the **Design Security Feature Disclaimer** by checking the box.

Figure 20. Design Security Feature Disclaimer



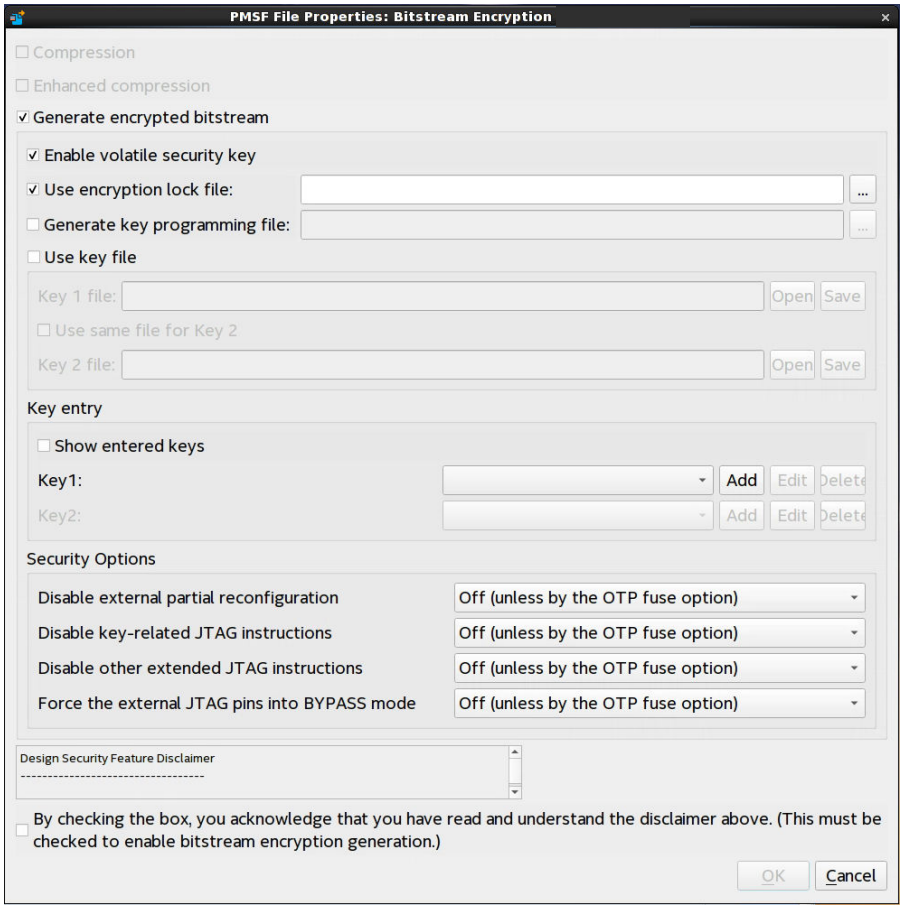
6. Click **OK**.
7. In **Programming File Generator**, click **Generate**. The PR bitstream files generate according to your specifications.

Generating PR Bitstreams with Convert Programming Files Dialog Box

Follow these steps to generate the `.rbf` with the **Convert Programming Files** dialog box:

1. Click **File ➤ Convert Programming Files**. The **Convert Programming Files** dialog box appears.
2. Specify the output file name and **Programming file type** as **Raw Binary File for Partial Reconfiguration (.rbf)**.
3. To add the input `.pmsf` file to convert, click **Add File**.
4. Select the newly added `.pmsf` file, and click **Properties**.
5. Enable or disable any of the following options and click **OK**:
   - **Compression**—enables compression on PR bitstream.
   - **Enhanced compression**—enables enhanced compression on PR bitstream.
   - **Generate encrypted bitstream**—generates encrypted independent bitstreams for base image and PR image. You can encrypt the PR image even if your base image has no encryption. The PR image can have a separate encryption key file (`.ekp`). If you enable **Generate encrypted bitstream**, enable or disable the **Enable volatile security key**, **Use encryption lock file**, and **Generate key programming file** options.
6. Click **Generate**. The PR bitstream files generate according to your specifications.

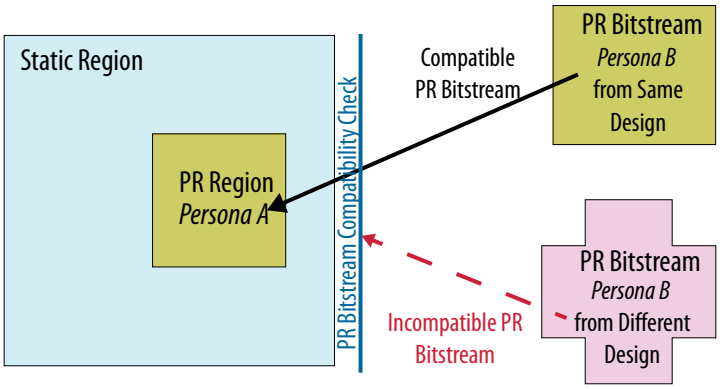
Figure 21. PMSF File Properties Bitstream Encryption



1.5.2. Partial Reconfiguration Bitstream Compatibility Checking

Partial reconfiguration bitstream compatibility checking verifies the compatibility of the reconfiguration bitstream to prevent configuration with an incompatible PR bitstream. The following sections describe PR bitstream compatibility check support.

Figure 22. PR Bitstream Compatibility Checking



PR Bitstream Compatibility Checking for Agilex 7, Agilex 5, and Stratix 10 Designs

For Agilex 7, Agilex 5, and Stratix 10 designs, PR bitstream compatibility checking is automatically enabled in the Compiler and in the Secure Device Manager (SDM) firmware by default. The following limitations apply to PR designs *if PR bitstream compatibility checking is enabled*:

- The firmware allows up to a total of 32 PR regions, irrespective of the number of hierarchical partial reconfiguration layers.
- Your PR design can have up to six hierarchical partial reconfiguration layers.
- Your PR design, when there is no hierarchy, can have up to 32 regions.
- Your PR design can have up to 15 child PR regions of any parent PR region (if it is hierarchical). Child PR regions count towards the total limit of 32 PR regions.

The Compiler generates an error if your PR design exceeds these limits when PR bitstream compatibility checking is enabled.

If you require more PR regions than this limitation allows, or otherwise want to disable PR bitstream compatibility checking , you can add the following assignment to the `.qsf` file:

```
set_global_assignment -name ENABLE_PR_POF_ID OFF
```

When you set this assignment to off, the limit of 32 total regions does not apply in the Compiler.

Note: If you require the PR bitstream authentication feature for your design, you must enable PR bitstream compatibility checking by setting the global assignment `ENABLE_PR_POF ID` to `ON`. The default setting is `ON`.

Arria 10 and Cyclone 10 GX PR Bitstream Compatibility Checking

For Arria 10 and Cyclone 10 GX designs, you enable or disable PR bitstream compatibility checking by turning on the **Enable bitstream compatibility check** option when instantiating the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP from the IP Catalog.

The PR IP verifies the partial reconfiguration PR Bitstream file (`.rbf`). When you enable the bitstream compatibility check, the PR `.pof` ID is encoded as the 71st word of the PR bitstream. If the PR IP detects an incompatible bitstream, then the PR IP stops the PR operation, and the status output reports an error.

When you turn on **Enable bitstream compatibility check**, the PR Controller IP core creates a **PR bitstream ID** and displays the bitstream ID in the configuration dialog box. For bitstream compatibility checking with hierarchical PR designs, refer to additional steps in *AN 806: Hierarchical Partial Reconfiguration Tutorial for Arria 10 GX FPGA Development Board*.

Related Information

AN 806: Hierarchical Partial Reconfiguration Tutorial for Intel Arria 10 GX FPGA Development Board

1.5.3. Raw Binary Programming File Byte Sequence Transmission Examples

The raw binary programming file (`.rbf`) file contains the device configuration data in little-endian raw binary format. The following example shows transmitting the `.rbf` byte sequence 02 1B EE 01 in x32 mode:

Table 10. Writing to the PR control block or SDM in x32 mode

In x32 mode, the first byte in the file is the least significant byte of the configuration double word, and the fourth byte is the most significant byte.

Double Word = 01EE1B02			
LSB: BYTE0 = 02	BYTE1 = 1B	BYTE2 = EE	MSB: BYTE3 = 01
D[7..0]	D[15..8]	D[23..16]	D[31..24]
0000 0010	0001 1011	1110 1110	0000 0001

1.5.4. Generating a Merged .pmsf File from Multiple .pmsf Files (Arria 10 and Cyclone 10 GX Designs)

Use a single merged `.rbf` file to reconfigure two PR regions simultaneously.

Note: This procedure supports only Arria 10 and Cyclone 10 GX devices. Agilex 7, Agilex 5, and Stratix 10 devices do not support merging `.pmsf` files.

To merge two or more `.pmsf` files:

1. Open the **Convert Programming Files** dialog box.
2. Specify the output file name and programming file type as **Merged Partial-Mask SRAM Object File (.pmsf)**.
3. In the **Input files to convert** dialog box, select **PMSF Data**.
4. To add input files, click **Add File**. You must specify two or more files for merging.
5. To generate the merged file, click **Generate**.

Alternatively, to merge two or more `.pmsf` files from the Quartus Prime shell, type the following command:

```
quartus_cpf --merge_pmsf=<number of merged files> <pmsf_input_file_1> \
     <pmsf_input_file_2> <pmsf_input_file_etc> <pmsf_output_file>
```

For example, to merge two `.pmsf` files, type the following command:

```
quartus_cpf --merge_pmsf=2 foo.pmsf bat.pmsf \
     combine.pmsf
```

After creating the merged `.pmsf`, generate a `.rbf`, as Generating PR Bitstream Files on page 26 describes.

1.6. Generating Programming Files for Intel FPGA Devices with Hard Processor Systems

When generating programming files for Intel FPGA devices with a Hard Processor System (HPS), you must first determine what boot flow you want to use for the device: HPS Boot First or FPGA Configuration First.

Depending on the boot flow that you want to use, follow the instructions in one of the following sections:

- Generating Programming Files for HPS Boot First Boot Flows on page 31
- Generating Programming Files for FPGA Configuration First Boot Flows on page 34

1.6.1. Generating Programming Files for HPS Boot First Boot Flows

In HPS Boot First boot flows, the HPS I/O and EMIF are configured and the HPS is booted before configuring the FPGA I/O and core.

Configuring the HPS I/O for the first time and then loading the HPS FSBL is called "Phase 1 configuration". The subsequent configuration of FPGA I/O and core by HPS is called "Phase 2 configuration".

To generate programming files for HPS Boot First boot flows:

1. Generate the primary programming files for your design, as Generating Primary Device Programming Files on page 5 describes.
2. Click **File ➤ Programming File Generator**.
3. For **Device family**, select your target device. The options available in the **Programming File Generator** change dynamically, according to your device and configuration mode selection.
4. For **Configuration mode**, select an Active Serial mode that your device supports. Configuration Modes (Programming File Generator) on page 9 describes all modes.
5. On the **Output Files** tab, select **Raw Binary File for HPS Core Configuration (.rbf)**, then select the following files:
   - **JTAG Indirect Configuration File for Periphery Configuration (.jic)**
   - **Raw Programming Data File (.rpd)**

   
   Secondary Programming Files (Programming File Generator) on page 10 describes all output files.
6. On the **Output Files** tab, select **Raw Programming Data File (.rpd)** and click **Edit**.
7. Optional: **Optional:** In the **RPD Properties** dialog box, set **Bit swap** to **On**.

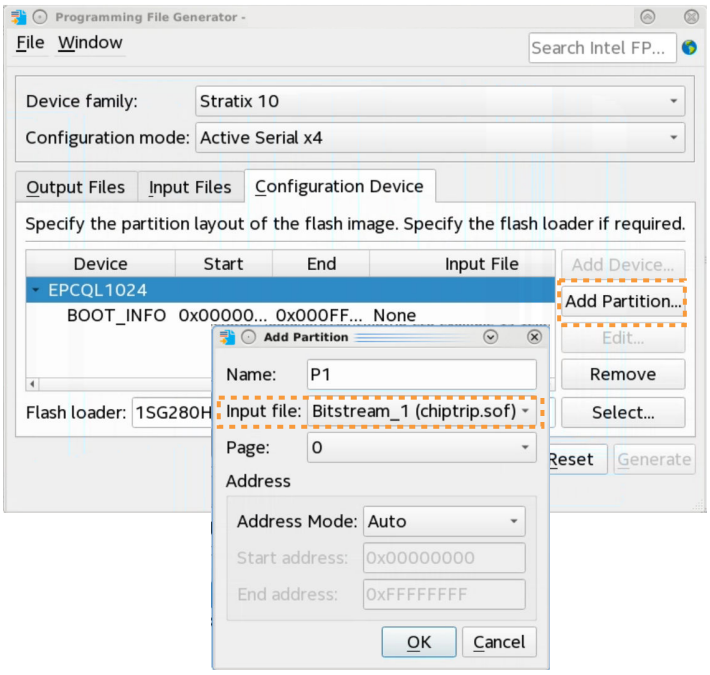
   Important: This step may or may not be required, depending on the external programmer that you use.

8. Specify the **Output directory** and **Name** for the file you generate. Output Files Tab Settings (Programming File Generator) on page 63 describes all options.
9. On the **Input Files** tab, click **Add Bitstream** to add your `.sof` file or files.
10. For each `.sof` file that you add, edit their properties as follows:
    a. Select the `.sof` file and click **Properties**.
    b. In the **Bootloader** field of **Input File Properties** dialog box, add the U-Boot First State Boot Loader (FSBL) file. Ensure that the file is an Intel-format hexadecimal (`.hex`) file.
11. To add other data, such as U-Boot Second Stage Boot Loader (SSBL) file or Phase 2 bitstreams:
    a. Click **Add Raw Data** and specify an Intel-format hexadecimal (`.hex`) file.
    b. Select the file you added and click **Properties**.
    c. In the **Input File Properties** dialog box, set the **Bit swap** field to **On**.

    Important: Your Phase 1 and Phase 2 bitstreams are subject to the following restrictions:
    - Your Phase 1 and Phase 2 bitstreams must be generated by the same version of Quartus Prime, including any applied patches or updates.
    - If your Phase 1 and Phase 2 bitstreams are generated from different Quartus Prime Pro Edition projects, review the following Knowledge Base article for additional steps that might be required:

      Why does FPGA configuration fail from Linux / u-boot fail on Stratix 10 10 SX devices when I use phase 2 bitstreams generated from different Quartus Projects?
12. To specify the `.sof` file that occupies the flash memory partition, click **Add Partition** on the **Configuration Device** tab. Add Partition Dialog Box (Programming File Generator) on page 66 describes all options.

Figure 23. Add Flash Partition



13. To select a supported flash memory device and predefined programming flow, click **Add Device** on the **Configuration Device** tab. Alternatively, click **<<new device>>** to define a new flash memory device and programming flow. Configuration Device Tab Settings on page 65 describes all settings.
14. Click the **Select** button for **Flash Loader** and select the device that controls loading of the flash memory device. Select Devices (Flash Loader) Dialog Box on page 69 describes all settings.
15. After you specify all options in **Programming File Generator**, the **Generate** button enables. Click **Generate** to create the files.
16. **Optional:** Export your settings to PFG setting file (`.pfg`) so that you can use these settings again with the `quartus_pfg` command line tool.

    For details, refer to quartus_pfg Command Line Tool on page 37.

- Stratix 10 Hard Processor System Remote System Update User Guide

1.6.2. Generating Programming Files for FPGA Configuration First Boot Flows

In FPGA Configuration First boot flows, the FPGA core and periphery are configured first. After that, the HPS can optionally be booted.

To generate programming files for FPGA Configuration First boot flows

1. Generate the primary programming files for your design, as Generating Primary Device Programming Files on page 5 describes.
2. Click **File ➤ Programming File Generator**.
3. For **Device family**, select your target device. The options available in the **Programming File Generator** change dynamically, according to your device and configuration mode selection.
4. For **Configuration mode**, select an Active Serial mode that your device supports. Configuration Modes (Programming File Generator) on page 9 describes all modes.
5. On the **Output Files** tab, select **JTAG Indirect Configuration File (.jic)**, then select the following files:
   - **Raw Binary File of Programming Helper Image (.rbf)**
   - **Raw Programming Data File (.rpd)**

   Secondary Programming Files (Programming File Generator) on page 10 describes all output files.
6. On the **Output Files** tab, select **Raw Programming Data File (.rpd)** and click **Edit**.
7. Optional: **Optional:** In the **RPD Properties** dialog box, set **Bit swap** to **On**.

   Important: This step may or may not be required, depending on the external programmer that you use.
8. Specify the **Output directory** and **Name** for the file you generate. Output Files Tab Settings (Programming File Generator) on page 63 describes all options.
9. On the **Input Files** tab, click **Add Bitstream** to add your `.sof` file and then edit its properties:
   a. Select the `.sof` file and click **Properties**.
   b. In the **Bootloader** field of **Input File Properties** dialog box, add the U-Boot First State Boot Loader (FSBL) hex file (`.hex`).
10. To add other data, such as a U-Boot Second Stage Boot Loader (SSBL) file or Phase 2 bitstreams:
    a. Click **Add Raw Data** and specify an Intel-format hexadecimal (`.hex`) file.
    b. Select the file you added and click **Properties**.
    c. In the **Input File Properties** dialog box, set the **Bit swap** field to **On**.

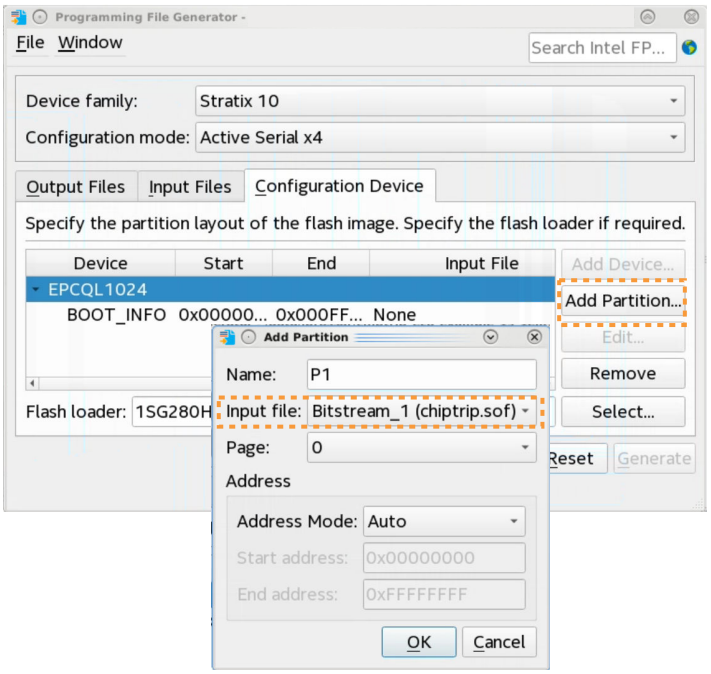
Important: Your Phase 1 and Phase 2 bitstreams are subject to the following restrictions:

- Your Phase 1 and Phase 2 bitstreams must be generated by the same version of Quartus Prime, including any applied patches or updates.
- If your Phase 1 and Phase 2 bitstreams are generated from different Quartus Prime Pro Edition projects, review the following Knowledge Base article for additional steps that might be required:

  Why does FPGA configuration fail from Linux / u-boot fail on Stratix 10 SX devices when I use phase 2 bitstreams generated from different Quartus Projects?

11. To specify the `.sof` file that occupies the flash memory partition, click **Add Partition** on the **Configuration Device** tab. Add Partition Dialog Box (Programming File Generator) on page 66 describes all options.

Figure 24. Add Flash Partition



12. To select a supported flash memory device and predefined programming flow, click **Add Device** on the **Configuration Device** tab. Alternatively, click **<<new device>>** to define a new flash memory device and programming flow. Configuration Device Tab Settings on page 65 describes all settings.
13. Click the **Select** button for **Flash Loader** and select the device that controls loading of the flash memory device. Select Devices (Flash Loader) Dialog Box on page 69 describes all settings.
14. After you specify all options in **Programming File Generator**, the **Generate** button enables. Click **Generate** to create the files.
15. Optional: **Optional:** Export your settings to a PFG setting file (`.pfg`) so that you can use these settings again with the `quartus_pfg` command line tool.

For details, refer to quartus_pfg Command Line Tool on page 37.

1.7. Scripting Support

The Quartus Prime software allows generating programming files from the command line. You can incorporate these commands to scripted flows.

1.7.1. quartus_pfg Command Line Tool

The Programing File Generator is also available as the `quartus_pfg` executable. You can specify conversion settings in the command line or through a PFG setting file (`.pfg`). This ability is useful for advanced designs that require multiple images or multiple user data files (HEX/RBF), because you define the settings once in the GUI and then export for subsequent use in the command line.

By default, `quartus_pfg` converts files using the AVSTx8 configuration scheme. To use a different flow, specify the proper operation mode, as the following command shows:

```
quartus_pfg -c  -o device=MT25QU512 -o mode=ASX4 -o flash_loader=1SG280HN3S3 \
      project.sof project.jic
```

To export PFG settings to a `.pfg` file, click **File ➤ Save**. The Programming File Generator only saves settings that are consistent.

For more information about the `quartus_pfg` executable, type the following in the command line:

```
quartus_pfg --help
```

Differences Between GUI and Command Line Tool

The command line tool supports single image conversion only.

1.7.2. quartus_cpf Command Line Tool

The Convert Programming Files tool is also available as the `quartus_cpf` command line executable. You can specify conversion settings in the command line or with a conversion setup file (`.cof`).

For help with the `quartus_cpf` executable, type the following at the command line:

```
quartus_cpf --help
```

1.7.2.1. Generating a Partial-Mask SRAM Object File using a Mask Settings File and a SRAM Object File

- To generate a `.pmsf` file with the `quartus_cpf` executable, type the following in the command line:

  ```
  quartus_cpf -p <pr_revision.msf> <pr_revision.sof> <new_filename.pmsf>
  ```

Note: The `-p` option is available for designs targeting Arria 10 and Cyclone 10 GX device families.

1.8. Generating Programming Files Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Added support for Agilex 5 devices. • Updated the description of map file in *Secondary Programming Files (Programming File Generator)*.
2023.04.03	23.1	• Updated location of device information directory in *Enabling Bitstream Encryption or Compression for Arria 10 and Cyclone 10 GX Devices*. • Updated product family name to "Intel Agilex 7."
2022.09.26	22.3	• Updated *Generating Secondary Programming Files (Programming File Generator)*. • *Updated Generating Secondary Programming Files (Settings: Programming Files Dialog Box).* • Removed footnotes saying that security features are not available for Agilex 7 devices. For details about security features for Agilex 7 devices, refer to the *Agilex 7 Device Security User Guide*.
2021.10.04	21.3	• Added *Generating Secondary Programming Files (Settings: Programming Files Dialog Box)* topic.
2020.12.14	20.4	• Added new *Generating Programming Files for the HPS Flash Programmer* section.
2020.10.13	20.3	• Added more details about alternate configuration schemes to *quartus_pfg Command Line Tool* topic.
2020.05.08	19.4	• Added note about programming file differences to *Generating Primary Device Programming Files* topic.
2019.12.16	19.4	• Added programming file generation support for Agilex 7 devices. • Noted Agilex 7 security feature limitations.
2019.09.30	19.3	• Added new "Enabling Bitstream Security for Intel Stratix 10 Devices" topic. • Added new "Enabling Bitstream Authentication (Programming File Generator)" topic. • Added new "Specifying Additional Physical Security Settings (Programming File Generator)" topic. • Added new "Enabling Bitstream Encryption (Programming File Generator)" topic. • Updated name of "Authentication and Encryption" tab to "Security" tab. • Added footnote about programming file support for Agilex 7 devices. • Described new **More Security Settings** dialog box.
2019.06.10	19.1	• Added links to *Generic Flash Programmer User Guide*. • Added flash programming details to "Generating Secondary Programming Files" and created separate topics for **Programming File Generator** and **Convert Programming Files** dialog box. • Added new "Enabling Bitstream Encryption or Co-Signing (Programming File Generator)" topic. • Added new "Enabling Bitstream Compression or Encryption (Convert Programming File)" topic. • Updated screenshots for latest GUI.
2019.04.01	19.1	• Retitled and reorganized topics to improve flow of information. • Added "Programming File Generator Configuration Modes" topic. • Added "Convert Programming File Configuration Modes" topic. • Added "Generating Programming Files for Partial Reconfiguration." • Added "Generating PR Bitstreams Files."

continued...

Document Version	Quartus Prime Version	Changes
		• Added "Partial Reconfiguration Bitstream Compatibility Checking." • Added "Raw Binary Programming File Byte Sequence Transmission Examples." • Added "Generating a Merged .pmsf File from Multiple .pmsf Files."
2018.10.09	18.1	• Added MAX V to the list of devices that the Programming File Generator tool supports. • Added table : *Device Families that the Convert Programming Files Tool Supports*.
2018.09.24	18.1	• Added topic: *quartus_cpf Command Line Tool*. • Stated that the Convert Programming Files dialog box is a legacy tool that supports file conversion for older device families. • In topic: *Output File Types*, specified that the list includes file types generated by the Converting Programming Files tool.
2018.08.07	18.0	Reverted document title to *Programmer User Guide: Intel Quartus Prime Pro Edition*.
2018.06.27	18.0	• Created the new chapter with information from the *Programming Devices* chapter. • Included information about the Programming File Generator tool.

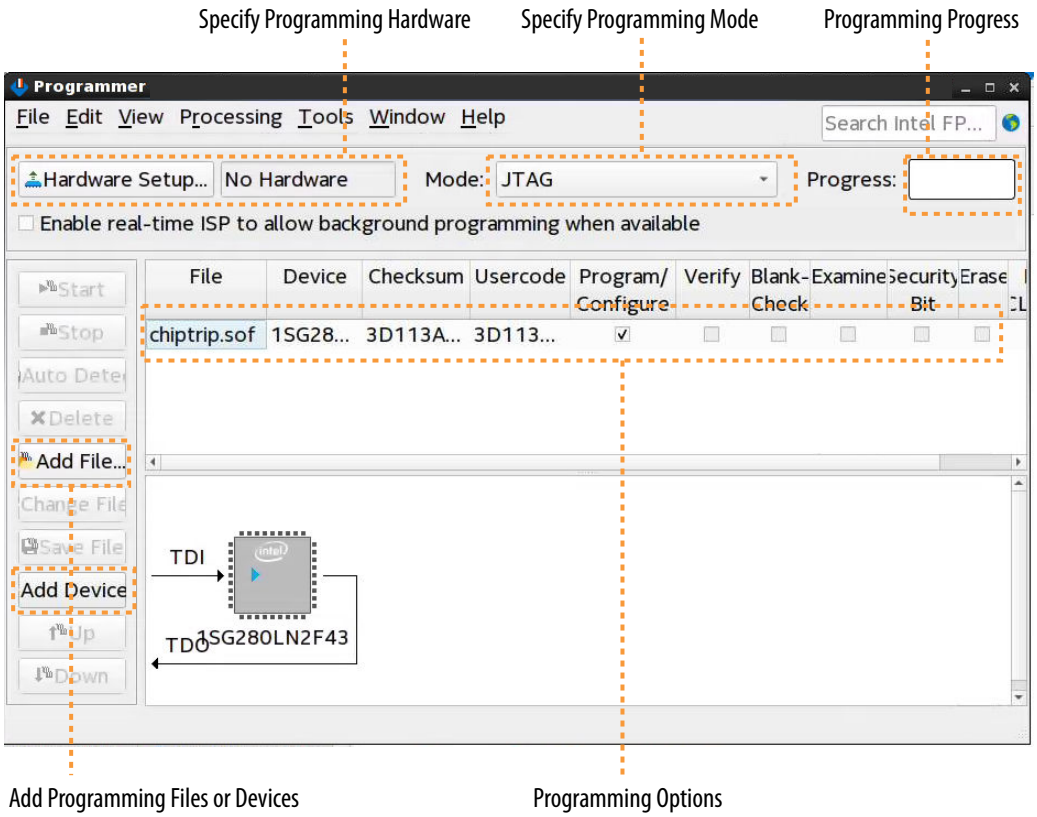
2. Using the Quartus Prime Programmer

Use the Quartus Prime Programmer and connected communication cable to program or configure Intel CPLD, FPGA, and configuration devices. This chapter describes how to setup and use the Quartus Prime Programmer.

2.1. Quartus Prime Programmer

Access the integrated Programmer by clicking **Tools ➤ Programmer** in the Quartus Prime software.

Figure 25. Quartus Prime Programmer



Prior to programming or configuration, you generate and specify the primary programming files, setup the programming hardware, and set the configuration mode in the Programmer.

2.2. Programming and Configuration Modes

The current version of the Quartus Prime Programmer supports the following programming and configuration modes in the Programmer's **Mode** list. Select a configuration mode to setup and run that type of programming or configuration.

Table 11. Programming and Configuration Modes

Programming or Configuration Mode	Description
JTAG	A configuration method that configures one or more devices through the Joint Test Action Group (JTAG) Boundary-Scan Test (BST) circuitry.
In-Socket Programming	Configuration device programming or testing via the Altera Programming Unit (APU).
Passive Serial	An external controller passes configuration data to one or more configuration devices via a serial data stream. The device is treated as a slave device with a 5-wire interface to the external controller. The external controller can be an intelligent host such as a microcontroller or CPU, or the Quartus Prime Programmer. The external controller can also be a serial configuration device.
Active Serial Programming	The active serial memory interface block loads design data into one or more devices. The active serial memory interface block controls the configuration process, and configures all of the devices in the chain using the configuration data stored in an EPCS1, EPCS4, EPCS16, EPCS64, EPCQ, EPCQL, and third-party QSPI serial configuration devices.

2.3. Basic Device Configuration Steps

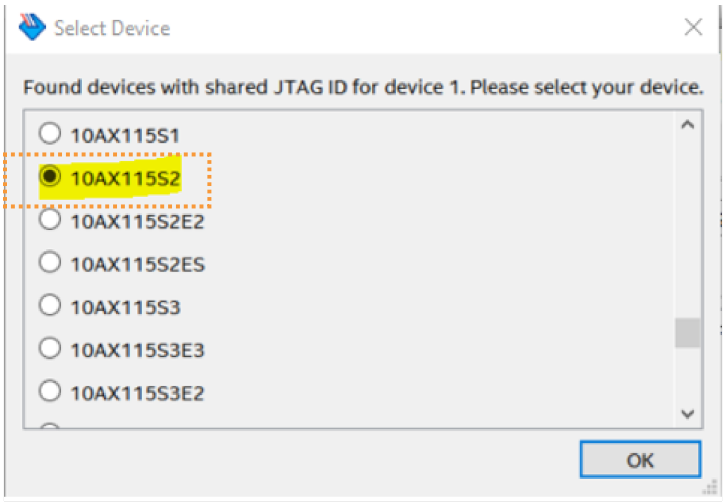
Basic FPGA Device Configuration over JTAG involves opening the Quartus Prime Programmer, connecting to a device on a development kit or board, and loading the configuration SRAM Object File (`.sof`) into the SRAM of the FPGA. The following steps describe the basic JTAG device configuration flow:

1. To run the Assembler to generate primary programming files, click **Processing ➤ Start ➤ Start Assembler**. The Compiler runs any prerequisite stages and generates programming files according to your specifications, as Generating Primary Device Programming Files on page 5 describes.
2. To open the Programmer, click **Tools ➤ Programmer**.
3. Connect the board cables. For JTAG device configuration, connect the JTAG USB cable to the board, and connect the power cable attached to the board to a power source.
4. Turn on power to the board.
5. In the Programmer, select **JTAG** for the programming **Mode**, as Programming and Configuration Modes on page 41 describes.
6. Click **Hardware Setup**. In the **Hardware** list, select connected programming hardware, as Specifying the Programming Hardware Setup on page 43 describes.

Figure 26. Hardware Setup

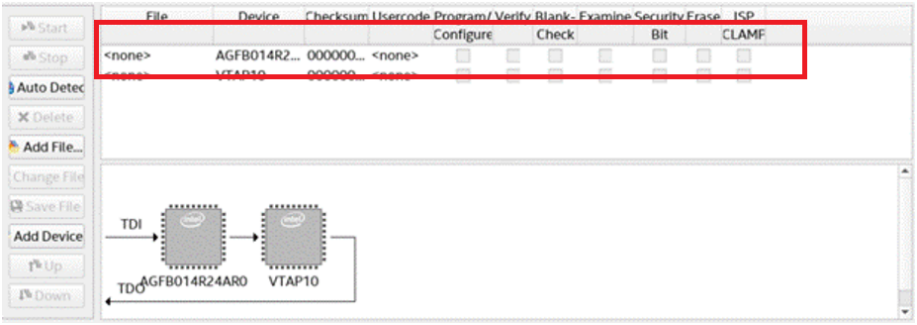
7. In the **Found Devices** list, select the device that matches your design and click **OK**.

Figure 27. Select Device



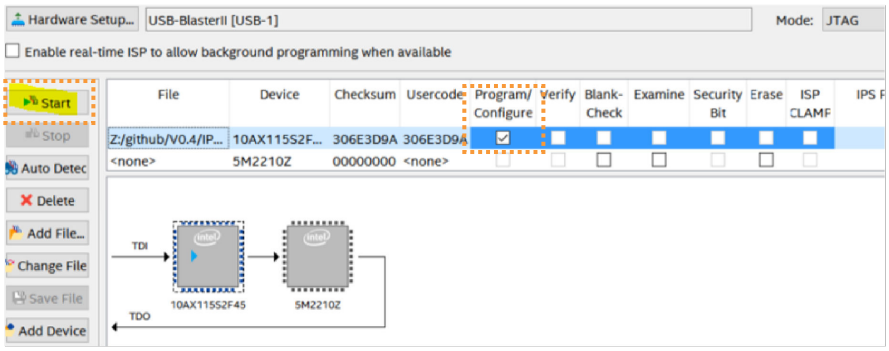
8. Right-click the row in the file list, and then click **Change File**.

Figure 28. Programmer Window



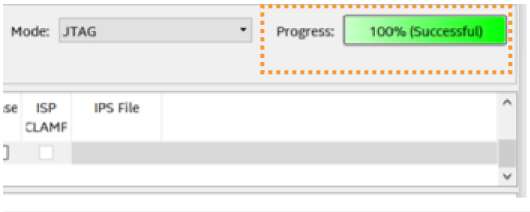
9. Browse to select the `.sof` file.
10. Enable the **Program/Configure** option for the row.

Figure 29. Program/Configure Option



11. Click **Start**. The progress bar reaches 100% when device configuration is complete. The device is now fully configured and in operation.

Figure 30. Programming Successful



Note: If device configuration fails, confirm that the device you select for configuration matches the device you specify during `.sof` file generation.

2.4. Specifying the Programming Hardware Setup

Before you can program or configure a device, you must specify an appropriate hardware setup. The Programmer's **Hardware Setup** dialog box allows you to add and remove programming hardware or JTAG servers from the current programming setup. You can specify a hardware setup for device programming or configuration, or configure a local JTAG server.

A JTAG server allows the Quartus Prime Programmer to access the JTAG programming hardware connected to a remote computer through the JTAG server of that computer. The JTAG server allows you to control the programming or configuration of devices from a single computer through other computers at remote locations. The JTAG server uses the TCP/IP communications protocol.

Selecting Device Programming Hardware

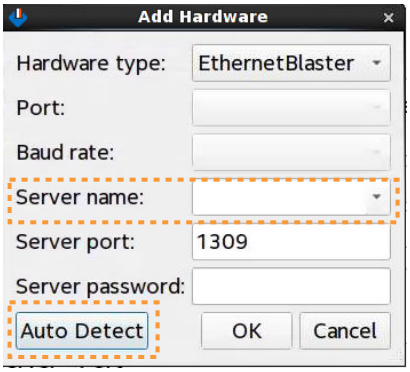
Follow these steps to select device programming hardware in the Programmer:

1. In the Programmer, click **Hardware Setup**.

Figure 31. Hardware Setup Dialog Box

2. To add new programming hardware, click **Add Hardware** on the **Hardware Settings** tab. In the **Add Hardware** dialog box, click **Auto Detect** to detect your programming hardware, or specify the properties of your programming hardware.

Figure 32. Add New Hardware



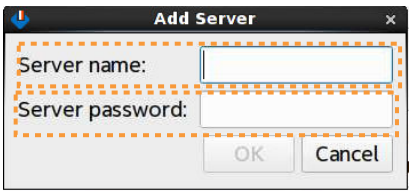
3. On the **Hardware Settings** tab, select your connected programming hardware in **Currently selected hardware**. This list is empty until you connect and add programming hardware to your system.
4. Enable or disable **Auto-adjust frequency at chain scanning** to automatically adjust the **Hardware frequency** according to the frequency at chain scanning.
5. Click **Close**. The setup appears as the current hardware setup.

Selecting a JTAG Server for Device Programming

Follow these steps to select a JTAG server for device programming in the Programmer:

1. In the Programmer, click **Hardware Setup**.
2. On the **JTAG Settings** tab, click **Add Server**. In the **JTAG Settings** dialog box, specify the **Server name** and **Server password**.

Figure 33. JTAG Settings



3. Under **JTAG Servers**, select the JTAG server that you want to access for programming.
4. Click **Close**. The setup appears as the current hardware setup.

2.4.1. JTAG Chain Debugger Tool

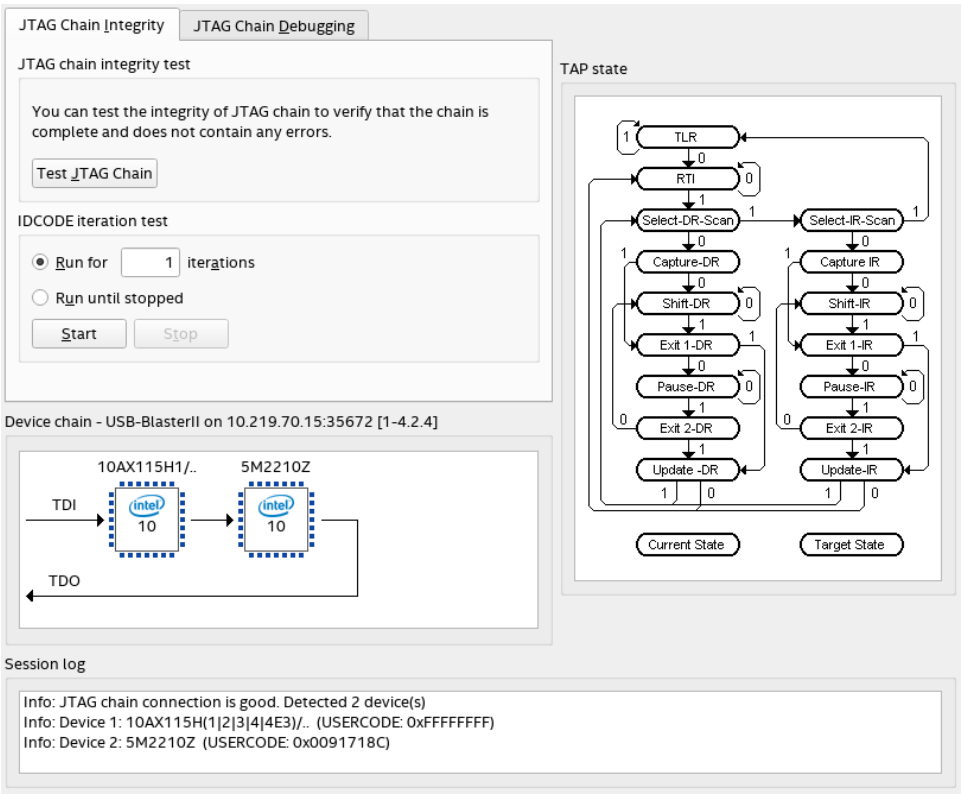
The JTAG Chain Debugger tool allows you to test the JTAG chain integrity and detect intermittent failures of the JTAG chain.

Access the tool by clicking **Tools ➤ JTAG Chain Debugger** in the Quartus Prime software.

Figure 34. JTAG Chain Debugger (Using an Arria 10 GX Development Kit)

The JTAG Chain Debugger has the following panes:

- **JTAG Chain Integrity** tab
- **JTAG Chain Debugging** tab
- **Device chain** pane
- **Tap state** pane
- **Session log** pane



The tool also allows you to shift in JTAG instructions and data through the JTAG interface, and step through the test access port (TAP) controller state machine for debugging purposes.

If the JTAG Chain Debugger Tool GUI is disabled when first you open it, enable the tool by selecting hardware:

1. In the JTAG Chain Debugger Tool GUI, select **Edit ➤ Hardware Setup**.
2. In the **Hardware Settings** tab of the **Hardware Setup** window, select a hardware device in the **Currently selected hardware** field.

If no hardware is available to select, add hardware by clicking **Add Hardware**.

Initially, the **Device chain** pane is empty. To populate the **Device chain** pane, right-click in the pane and select **Test JTAG chain**, or click **Test JTAG Chain** on the **JTAG Chain Integrity** tab.

When the **Device chain** pane is populated, you can activate one or all devices in the chain to run the test on the activated device or devices. To activate a device or all devices in the **Device chain** pane, the **JTAG Chain Debugging** tab must be selected.

Tests are run only on activated devices. Devices that are not activated are bypassed during testing.

You can save the contents of the **Session log** pane to repeat the session in the **JTAG Chain Debugging** tab, or you can clear the log:

- To save the log to replay later, right-click anywhere in the **Session log** pane and select **Save Session Log**.
- To clear the log, right-click anywhere in the **Session log** pane and select **Clear Session Log**.

Related Information

- Agilex 7 JTAG Boundary-Scan Testing User Guide
- Stratix 10 JTAG Boundary-Scan Testing User Guide
- JTAG Boundary-Scan Testing in Arria 10 Devices
- JTAG Boundary-Scan Testing in Cyclone 10 GX Devices

2.4.1.1. JTAG Chain Integrity Tab

Use the **JTAG Chain Integrity** tab to check the JTAG chain for potential failure, which can be caused by either a short circuit or an open JTAG circuit.

Figure 35. JTAG Chain Integrity Tab

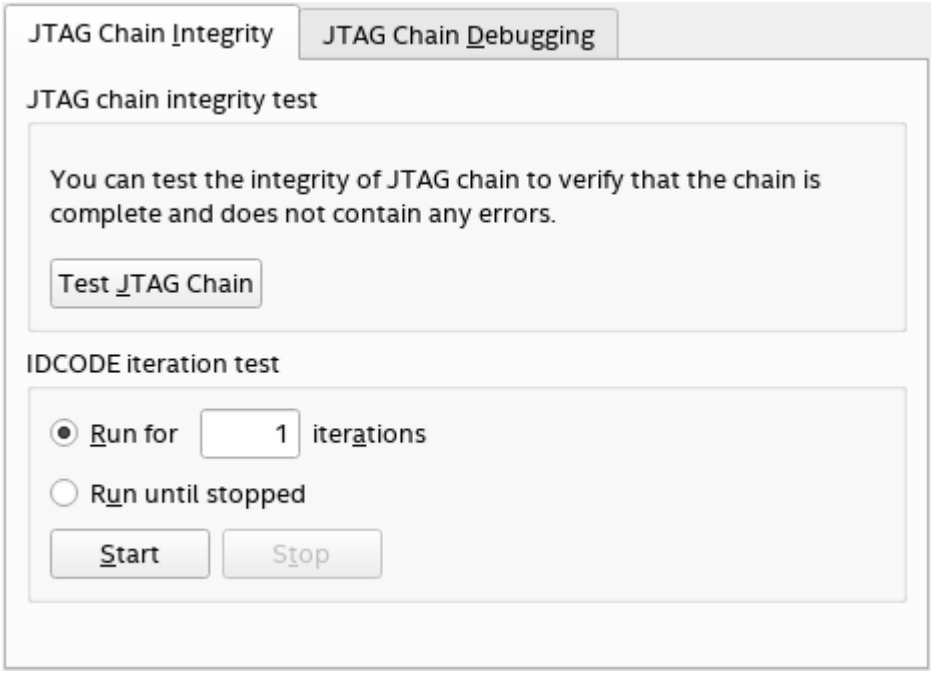


Table 12. JTAG Chain Integrity Tab

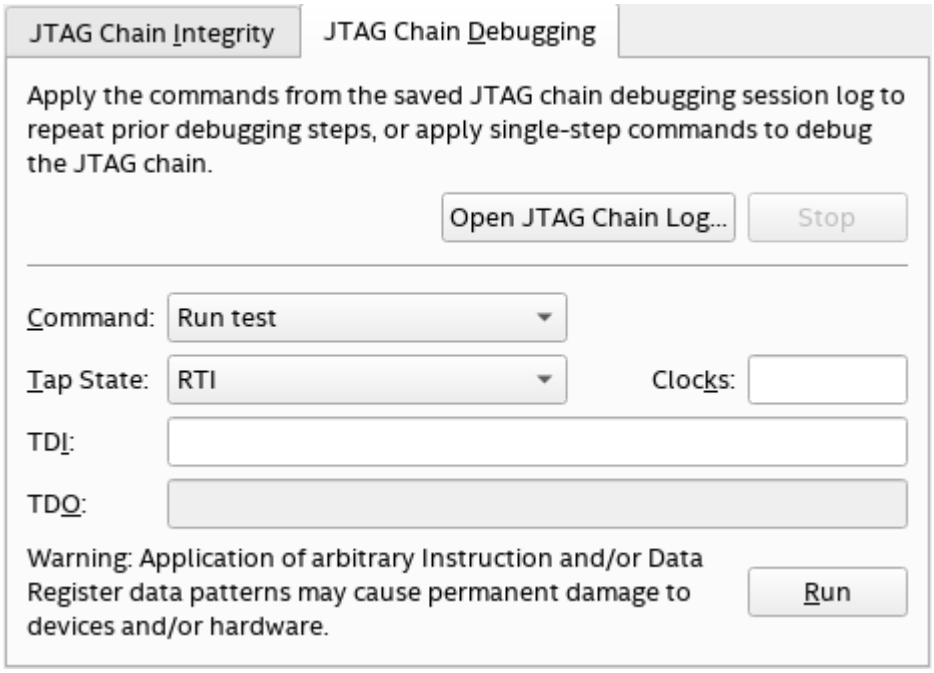
Pane	Description
JTAG chain integrity test	Run the Programmer **Auto Detect** feature, which detects devices in a chain and automatically adds supported devices to the **Device** list in the Programmer. The devices are added in the order in which they exist in the device chain. If the **Auto Detect** feature fails to detect the JTAG chain, click **Test JTAG Chain** to run a JTAG chain integrity test to analyze the failure.
IDCODE iteration test	Test for chain integrity and intermittent JTAG chain communication failure. This feature is turned off by default. • — **Run for**<*number*>**iterations**–specify the number of tests that you want to repeat. — **Run until stopped**–cycle the test repeatedly until you click **Stop**. The IDCODE iteration test cycles through Reset and Shift DR states to read IDCODEs from the device chain, and reports the following information: • When the IDCODEs read in each cycle of the test are the same, the result indicates that there are no inconsistencies or failures in the device chain. • When the IDCODEs read in each cycle are inconsistent, an error message is reported and the test terminates. Results from the IDCODE iteration test appear in text format in the **Session log** pane and in graphic format in the **Device chain** pane.

2.4.1.2. JTAG Chain Debugging Tab

Use the **JTAG Chain Debugging** tab to debug your JTAG chain by running commands to step through the state of the JTAG TAP controller. You can also repeat the commands from a previous session.

Figure 36. JTAG Chain Debugging Tab



When the **JTAG Chain Debugging** tab is active, you can use the **Device chain** pane to activate either a single device or all available devices:

- To activate a single device, click a device in the **Device chain** pane to select it and then right-click the device and select **Activate selected device**.
- To activate all available devices, right-click the **Device chain** pane background and select **Activate all devices**.

If the **Device chain** pane is empty, populate the **Device chain** pane by right-clicking in the pane and selecting **Test JTAG chain**. You can also click **Test JTAG Chain** on the **JTAG Chain Integrity** tab.

Table 13. JTAG Chain Debugging Tab

Task	Description
Playback the debugging sequence	Apply the commands from a saved JTAG debugging session log to repeat prior debugging steps: • **Open JTAG Chain Log**–browse to, open, and run a saved JTAG Chain Debugger session log. • **Stop**–stop the running of the commands from the saved session log.
Manually shift the JTAG sequence	Apply single-step commands:

continued...

Task	Description
	• **Command**–run one of the following commands for debugging the JTAG chain: — **Run test**–place the TAP controller in the specified state for a specified number of clocks. — **Scan Instruction Register**–specify a scan pattern that you can apply to the target instruction registers. — **Scan Data Register**–specify a scan pattern that you can apply to the target data registers. — **Goto State**–move the TAP controller from one stable state to another for further testing. You can also double-click a state in the **TAP state** pane to run this command. • **TAP state**–set the target state for the commands. The selected target state are reflected. • **Clocks**–specify the number of clocks to use when running a command. • **TDI**–specify the command data that is sent via TDI pins • **TDO**–shows command scan results read from TDO pins • **Run**–apply the selected **Command** and **Option** setting to the JTAG chain.

2.4.2. Editing the Details of an Unknown Device

When the Quartus Prime Programmer automatically detects devices with shared JTAG IDs, the Programmer prompts you to specify the device in the JTAG chain. If the Programmer does not prompt you to specify the device, you must manually add each device in the JTAG chain to the Programmer, and define the instruction register length of each device.

To edit the details of an unknown device, follow these steps:

1. Double-click the unknown device listed under the device column.
2. Click **Edit**.
3. Change the device **Name**.
4. Specify the **Instruction register length**.
5. Click **OK**.
6. Save the `.cdf` file.

2.4.3. Running JTAG Daemon with Linux

The JTAGD daemon is the Linux version of a JTAG server. The JTAGD daemon allows a remote machine to program or debug boards connected to a Linux host over the network. The JTAGD daemon also allows programs to share JTAG resources.

Running the JTAGD daemon prevents:

- The JTAGD server from exiting after two minutes of idleness.
- The JTAGD server from not accepting connections from remote machines, which might lead to an intermittent failure.

To run JTAGD as a daemon:

1. Create an `/etc/jtagd` directory.
2. Set the permissions of this directory and the files in the directory to allow read/write access.
3. Execute `jtagd` (with no arguments) from the `quartus/bin` directory.

The JTAGD daemon is now running and does not terminate when you log off.

2.5. Programming with Flash Loaders

Parallel and serial configuration devices do not support the JTAG programming interface. However, you can use a flash loader to program configuration devices in-system via the JTAG interface. The flash loader allows an FPGA to function as a bridge between the JTAG interface and the configuration device. The Quartus Prime software supports various parallel and serial flash loaders for programming bitstream storage and configuration via flash memory devices.

Refer to the following documents for step-by-step flash programming instructions.

Related Information

- Generic Serial Flash Interface Intel FPGA IP Core User Guide
- Intel Parallel Flash Loader IP Core User Guide
- Generic Flash Programmer User Guide
- Customizable Flash Programmer User Guide

2.5.1. Specifying Flash Partitions

Flash partitions allow you to store bitstreams or raw data.

Note: The **Programming File Generator** supports defining flash partitions only for `.jic` or `.pof` programming files.

To create flash partitions in the **Configuration Devices** tab:

1. Select the device and click **Add Partition**.
2. In the **Add Partition** dialog box, define the following parameters, and then click **OK**:

Table 14. Add Partition Dialog Box Settings

Setting	Description
Name	Name that you give to the partition.
Input file	Input file to program into the flash partition.
Page	Configuration devices can store multiple configuration bitstreams in flash memory, called pages. CFI configuration devices can store up to eight configuration bitstreams. Hyperflex® devices can store up to four configuration bitstreams, including the factory image. In Hyperflex devices, with the remote system update feature enabled, **Page** represents the parity.
Address Mode	The options are: • **Auto**—automatically allocates a block in the flash device to store the data. • **Block**—specify the start and end address of the flash partition. • **Start**—specify the start address of the partition. The tool assigns the end address of the partition based on the input data size.
Start address	Specifies the start address of the partition. Only enabled when **Address Mode** is **Block** or **Start**.
End address	Specifies the end address of the partition. Only enabled when **Address Mode** is **Block**.

The partition associated to the device appears in the device list.

3. If you want to change the parameters of a partition, click the partition and then click **Edit**.
4. If you want to remove a partition, click the partition and then click **Remove**.
5. After specifying the settings for all flash partitions, click **Generate.**

2.5.2. Full Erase of Flash Memory Sectors

When performing flash memory erase operations via JTAG and a `.jic` file, the Quartus Prime Programmer erases only the flash memory sectors that the `.jic` specifies.

For example, if you specify a `.jic` file containing only a 13.6Mbits FPGA image on an EPCQ64A device, the Programmer erases only the bottom 13.6Mbits, and does not erase the remaining 50.4Mbits of data.

To erase the entire flash memory device contents, do not specify a `.jic` file for flash programming. Rather, manually add the flash device to the associated FPGA device chain by following these steps:

1. In the Programmer, right-click the target FPGA device, and then click **Edit ➤ Attach Flash Device**.
2. Select the appropriate flash device from the list. The Factory Default Serial Flash Loader loads for the FPGA automatically.
3. In the Programmer, enable the **Erase** checkbox, and click **Start** to start the erase operation.

2.6. Verifying the Programming File Source with Project Hash

Quartus Prime programming files support the project hash property, which identifies the source project from which programming files generate.

During compilation, the Quartus Prime software generates a unique project hash, and embeds this hash value in the programming files (`.sof`). You can verify the source of programming files by matching the project and programming file hash values.

The project hash does not change for different builds of the Quartus Prime software, or when you install a software update. However, if you upgrade any IP with a different build or patch, the project hash changes.

2.6.1. Obtaining Project Hash for Arria 10 Devices

To obtain the project hash value of a `.sof` programming file for a design, use the `quartus_asm` command-line executable (`quartus_asm.exe` in Windows) with the `--project_hash` option.

```
quartus_asm --project_hash <sof-file>
```

Example 1. Output of Project Hash Command:

In this example, the programming file is `worm.sof`.

```

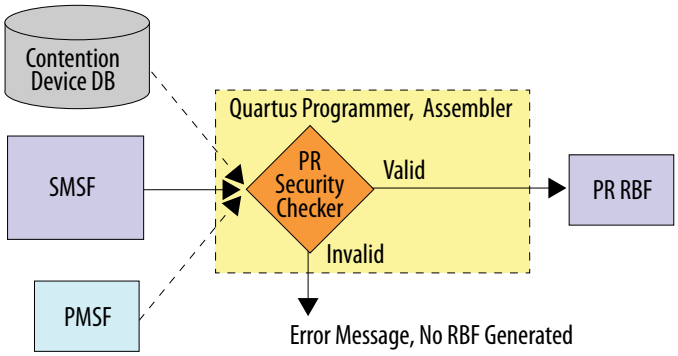
2.7. Using PR Bitstream Security Verification (Stratix 10 Designs)

PR bitstream validation confirms that the persona does not use FPGA resources that are unauthorized by the `.smsf`.

Thereafter, the Programmer requires both the `.pmsf` and `.smsf` to generate the PR bitstream (`.rbf`) for this PR region, ensuring that the PR persona can only change bits that the persona owns. The Platform Owner can optionally release `.smsf` files to third-party Clients as part of the PR region collateral. The Platform Owner uses the `.smsf` to generate the PR bitstream from Client's `.pmsf` for this PR region.

Figure 37. PR Bitstream Security Validation in Programmer



The Platform Owner should follow these steps to license, enable, and use PR bitstream security verification:

1. Obtain the license file to enable generation of `.smsf` files for PR regions during base compilation, and to perform PR bitstream security verification during PR bitstream generation in the Programmer. To obtain the license, login or register for a My-Intel account, and then submit an Intel Premier Support case requesting the license key.
2. To add the license file to the Quartus Prime Pro Edition software, click **Tools ➤ License Setup** and specify the feature **License File**.
3. To enable PR security validation features, add the following line to the project `.qsf`:

```
set_global_assignment -name PR_SECURITY_VALIDATION on
```

4. Compile the base revision.
5. Following base compilation, view the Assembler reports to view the generated `.smsf` files required for bitstream generation for each PR region.
6. The Client provides the `.pmsf` to the Platform Owner.
7. The Platform Owner verifies the `.pmsf`, converts the `.pmsf` to `.rbf`, and configures the FPGA device with the `.rbf`.
8. The platform owner converts the `.pmsf` to a PR bitstream. Providing the `.smsf` file to `quartus_cmf` instructs the tool to validate the `.pmsf` against that `.smsf`, and then to generate a bitstream only if the files are compatible.

```
quartus_cpf -c –-smsf=<smsf_file> <pmsf_file> <output_file>
```

2.8. Stand-Alone Programmer

The free Stand-Alone Programmer is available and has the same full functionality as the Quartus Prime Programmer.

The Stand-Alone Programmer is useful when programming devices on a workstation that does not have an Quartus Prime software license. The Stand-Alone Programmer does not require a separate Quartus Prime software license. Download the Stand-Alone Programmer from the Download Center on the Intel website.

Related Information

Download Center for FPGAs

2.8.1. Stand-Alone Programmer Memory Consumption

The following operations increase memory usage in the Stand-Alone Programmer:

- Auto-detect
- Adding programming files to the flash memory
- Manually attaching the flash in the Programmer

In Windows systems, the Stand-Alone Programmer has the following memory limitations:

Table 15. Stand-Alone Programmer Memory Limitations

Application	Maximum Flash Device Size	Flash Device Operation Using PFL
64-bit Stand-Alone Programmer	Up to 2 Gb	Multiple Flash Device

2.9. Programmer Settings Reference

The following topics describe Quartus Prime settings that impact programming and programming file generation.

2.9.1. Device & Pin Options Dialog Box

The following tables describe **Device & Pin Option** settings that impact generation of primary and secondary programming files. To access these settings, click **Assignments ➤ Device ➤ Device & Pin Options**.

Table 16. General Device Options

Allow you to specify basic device configuration options that are independent of a specific configuration scheme. To access these settings, click **Assignments ➤ Device ➤ Device and Pin Options ➤ General**.

Option	Description
Options *Note:* Not supported for Agilex 7 or Stratix 10 devices.	• **Auto-restart configuration after error**—restarts the configuration process automatically if a data error is encountered. If this option is turned off, you must externally direct the device to restart the configuration process if an error occurs. This option is available for passive serial and active serial configuration schemes. • **Release clears before tri-states**—releases the clear signal on registered logic cells and I/O cells before releasing the output enable override on tri-state buffers. If this option is turned off, the output enable signals are released before the clear overrides are released. • **Enable user-supplied start-up clock (CLKUSR)**—uses a user-supplied clock on the CLKUSR pin for initialization. When turned off, external circuitry is required to provide the initialization clock on the DCLK pin in the Passive Serial and Passive Parallel Synchronous configuration schemes; in the Passive Parallel Asynchronous configuration scheme, the device uses an internal initialization clock. • **Enable device-wide reset (DEV_CLRn)**—enables the DEV_CLRn pin, which allows all registers of the device to be reset by an external source. If this option is turned off, the DEV_CLRn pin is disabled when the device operates in user mode and is available as a user I/O pin. • **Enable device-wide output enable (DEV_OE)**—enables the DEV_OE pin when the device is in user mode. If this option is turned on, all outputs on the chip operate normally. When the pin is disabled, all outputs are tri-stated. If this option is turned off, the DEV_OE pin is disabled when the device operates in user mode and is available as a user I/O pin. • **Enable INIT_DONE output**—enables the INIT_DONE pin, which allows you to externally monitor when initialization is complete and the device is in user mode. If this option is turned off, the INIT_DONE pin is disabled when the device operates in user mode and is available as a user I/O pin.

continued...

Option	Description
	• **Enable JTAG Pin Sharing**—enables the JTAG pin sharing feature. The JTAGEN pin is enables and becomes a dedicated input pin in user mode. JTAG pins (TDO, TCK, TDI, and TMS pins) are available as test pins when the JTAGEN pin is pull low. JTAG pins are dedicated when the JTAGEN pin is high. If this option is turned off, the JTAGEN pin is disabled when the device operates in user mode and is available as a user I/O pin. JTAG pins are retained as dedicated JTAG pins. • **Enable nCONFIG, nStatus, and CONF_DONE pins**—enables the major configuration pins, nCONFIG, nSTATUS, and CONF_DONE pin in user mode. If this option is turned off, the nCONFIG, nSTATUS, and CONF_DONE pins are disabled when the device operates in user mode and are available as user I/O pins. • **Enable OCT_DONE** —enables the OCT_DONE pin, which controls whether the INIT_DONE pin is gated by OCT_DONE pin. If this option is turned off, the INIT_DONE pin is not gated by the OCT_DONE pin. • **Enable security bit support**—enables the security bit support, which prevents data in a device from being obtained and used to program another device. This option is available for supported device (MAX II, and MAX V) families. • **Set unused TDS pins to GND**—sets the unused temperature sensing diode TSD pins, TEMPDIODEp and TEMPDIODEn to GND in the pin. By default, TSD pins are available for connection to an external temperature sensing device; however, you must manually connect the pins to GND if they are not connected. When turned on, this option updates the information in the .pin file and does not affect FPGA behavior. • **Enable CONFIG_SEL pin**—enables the BOOT_SEL pin in user mode. If this option is turned off, the BOOT_SEL pin is disabled when the device operates in user mode and is available as a user I/O pin. • **Enable nCEO pin**—enables the nCEO pin. This pin should be connected to the nCE of the succeeding device when multiple devices are being programmed. If this option is turned off, the nCEO pin is disabled when the device operates in user mode and is available as a user I/O pin. • **Enable autonomous PCIe HIP mode**—releases the PCIe HIP after periphery configuration, before device core configuration completes. This option only takes effect if CvP mode is disabled. • **Enable the HPS early release of HPS IO**—releases the HPS shared I/O bank after the IOCSR programming.
Auto usercode	Sets the JTAG user code to match the checksum value of the device programming file. The programming file is a .pof for non-volatile devices, or an .sof for SRAM-based devices. If you turn on this option, the **JTAG user code** option is not available.
JTAG user code	Specifies a hexadecimal number for the device selected for the current Compiler settings. The JTAG user code is an extension of the option register. This data can be read with the JTAG USERCODE instruction. If you turn on **Auto usercode**, this option is not available.
In-system programming clamp state	Allows you to specify the state that the pins take during in-system programming for used pins that do not have an in-system programming clamp state assignment. Unused pins and dedicated inputs must always be tri-stated for in-system programming. Used pins are tri-stated by default during in-system programming, which electrically isolates the device from other devices on the board. At times, however, in order to prevent system damage you may want to specify the logic level for used pins during in-system programming. The following settings are available:

continued...

Option	Description
	• **Tri-state**—the pins are tri-stated. • **High**—the pins drive VCCIO. • **Low**—the pins drive GND. • **Sample and Sustain**—the pins drive the level captured during the SAMPLE/PRELOAD JTAG instruction.
Configuration clock source	Specifies the clock source for device initialization (the duration between CONF_DONE signal went high and before INIT_DONE signal goes high). For AS x1 or AS x4 configuration mode, you can select either **Internal Oscillator** or **CLKUSR** pin only. The DCLK pin is an illegal option for AS mode. In 14 nm device families, only **Internal Oscillator** or **OSC_CLK_1** pins are available.
Device initialization clock source	Specifies the clock source for device initialization (the duration between CONF_DONE signal went high and before INIT_DONE signal goes high). For AS x1 or AS x4 configuration mode, you can select either **Internal Oscillator** or **CLKUSR** pin only. The DCLK pin is an illegal option for AS mode. In 14 nm device families, only **Internal Oscillator** or **OSC_CLK_1** pins are available.

Table 17. Configuration Options

Allow you to specify the configuration scheme, configuration device and pin options, serial clock source, and other options for subsequent device configuration with your programming bitstream. To access these settings, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Configuration**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Configuration scheme	Specifies the scheme of configuration for generation of appropriate primary and secondary programming files, such as **Active Serial x4**. Only options appropriate for the current **Configuration Scheme** are available.
Configuration Device	Allows you to specify options for an external configuration device that stores and loads configuration data. • **Configuration device I/O voltage**—specifies the VCCIO voltage of the configuration pins for the current configuration scheme of the target device. This option is available for supported device families. • **Force VCCIO voltage to be compatible with configuration I/O voltage**—forces the VCCIO voltage of the configuration pins to be the same as the configuration device I/O voltage. If you turn off this option, the VCCIO voltage of the configuration pins may vary depending on the I/O standards used in the I/O banks containing the configuration pins. This option is available for supported device families.
Configuration Pin Options	Enables or disables operation of specific device configuration pins for status monitoring, SEU error detection, CvP, and other configuration pin options.
Generate compressed bitstreams	Generates compressed bitstreams and enables bitstream decompression in the target device.
Active serial clock source	Specifies the configuration clock source for Active Serial programming. Options range from 12.5 MHz to 100 MHz.
VID Operation Mode	Enables Voltage Identification logic in the target device with selected operation mode. The available options are **PMBus Master** or **PMBus Slave**.
HPS/FPGA configuration order	For hard processor system (HPS) configuration, specifies the order of configuration between the HPS and FPGA. The options are **HPS First**, **After INIT_DONE**, and **When requested by FPGA**.
HPS debug access port	• **Disabled**—the HPS JTAG is not enabled. • **HPS Pins**—the HPS JTAG is routed to the HPS dedicated I/O. • **SDM Pins**—the HPS JTAG is chained to the FPGA JTAG.
Disable Register Power-Up Initialization	Specifies whether the Assembler generates a bit stream with register power-up initialization.

Table 18. Unused Pin Options

Allow you specify the reserve state of all the unused pins on the device. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Unused Pins**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Reserve all unused pins	• **As input tri-stated**—the pins reserve as tri-state input pins. • **As output driving ground**—the pins reserve as output pins and drive the ground signal. • **As output driving an unspecified signal**—the pins reserve as output pins and drive any signal. • **As input tri-stated with bus-hold circuitry**—the pins reserve as tri-state input pins with bus-hold circuitry. • **As input tri-stated with weak pull-up**—the pins reserve as tri-state input pins with weak pull-up resistors.

Table 19. Dual-Purpose Pin Options

Allow you to specify whether the associated dual-purpose pin is reserved, and the reservation purpose. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Dual-Purpose Pins**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Dual-purpose pins	• **Use as regular I/O**—the dual-purpose pin is not reserved. Rather the I/O pin is in in user mode. • **Use as programming pin**—the nCE0 pin is reserved as a dedicated programming pin. • **As input tri-stated**—the dual-purpose pin is reserved as an input pin. • **As output driving ground**—the dual-purpose pin is reserved as an output pin and drives the ground signal. • **As output driving an unspecified signal**—the dual-purpose pin is reserved as an output pin and drives any signal. • **Compiler configured**—the Compiler automatically selects the best reserve setting for the dual-purpose pin, considering the current configuration scheme, and whether the pins are only used for configuration. If your design uses the Active Parallel configuration scheme and the Programmer does not communicate directly with the parallel flash device in user mode, you should reserve all dual-purpose pins connected to the parallel flash device as Compiler configured.

Table 20. Board Trace Model Options

For Cyclone 10 GX designs only, allows you to specify the board trace, termination, and capacitive load parameters for each I/O standard. The board trace model parameters then apply to all output or bidirectional pins that you assign with the specified I/O standard. Board trace model parameters do not apply if you assign them to anything other than an output or bidirectional pin. You can create board trace model assignments for individual output or bidirectional pins in the Pin Planner. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Board Trace Model**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
I/O standard	Specifies the supported I/O standard, such as **Differential 1.8-V SSTL Class II**.
Board trace model	Lists the board trace model parameters, with units, and values for the specified **I/O standard**. You can change the value of each parameter. The board trace model assignments apply to all output and bidirectional pins with the specified I/O standard assigned to them.

Table 21. I/O Timing Options

Allow you to specify the node at which output I/O timing terminates. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ I/O Timing**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Default timing I/O endpoint	Specify **Near end** or **Far end**.

Table 22. Voltage Options

Allow you to specify the default I/O bank voltage for pins on the target device. Also displays the core voltage of the device or other internal voltage information. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Voltage**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Default I/O standard	Specify **1.2 V**, **1.5 V**, **1.8 V**, **2.5 V**, **3.0 LVTTL**, or **3.0 LVCMOS**.

Table 23. Error Detection CRC Options

Allow you to specify whether to use error detection cyclic redundancy check (CRC) and the value by which you want to divide the error check frequency for the currently selected device. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Error Detection CRC**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Enable Error Detection CRC_ERROR pin	Enables error detection CRC and CRC_ERROR pin usage for the targeted device. This check determines the validity of the programming data in the device. Any changes in the data while the device is in operation generates an error. *Note:* Not available for Agilex 7 or Stratix 10 devices.
Enable Open Drain on CRC Error pin	Sets the CRC ERROR pin as an open-drain pin. This action decouples the voltage level of the CRC ERROR pin from VCCIO voltage. When you turn on this option, you must connect a pull-up resistor to the CRC ERROR pin. *Note:* Not available for Agilex 7 or Stratix 10 devices.
Enable error detection check	Enables error detection CRC checking to verify the validity of programming data in the device, and reports any changes in the data while the device is in operation.
Minimum SEU interval	Specifies the minimum time interval between two checks of the same bit. Setting to 0 means check as frequently as possible. Setting to a large value saves power. The unit of interval is millisecond. The maximum allowed number of intervals is 10000.
Enable internal scrubbing	Specifies use of internal scrubbing to correct any detected single error or double adjacent error within the core configuration memory while the device is still running.
Generate SEU sensitivity map file (.smh)	Generates a Single Event Upset Sensitivity Map file. This file allows you to enable the Advanced SEU detection feature.
Allow SEU fault injection	Allows the injection of fault patterns to test for SEU.
Enable external scrubbing	Enables the Assembler to provide hashes of configuration RAM (CRAM) content for all sectors within the SRAM Object File (SOF) option. *Note:* Available only for Agilex 5 device.
seu_error_out signal behavior	Controls the behavior of the `seu_error_out signal`. Either correctable or uncorrectable and only uncorrectable are the supported options. *Note:* Available only for Agilex 5 device.

Table 24. CvP Settings

Specifies the configuration mode for Configuration via Protocol (CvP). To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ CvP Settings**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Configuration via protocol	In **Initialization and update** mode, the periphery image stores in an external configuration device and loads the image into the FPGA through a conventional configuration scheme. The core image stores in a host memory and loads into the FPGA through the PCIe link. In **Core initialization** mode, the periphery image stores in an external configuration device and loads into the FPGA through the conventional configuration scheme. The core image is stores in a host memory and is loads into the FPGA through the PCIe link. In **Core update** mode, the

continued...

Option	Description
	FPGA device is initialized after initial system power up by loading the full configuration image from the external local configuration device to the FPGA. You can use the PCIe link to perform one or more FPGA core image update through this mode. In the **Off** mode, CvP is turned off.
Enable CvP_CONFDONE pin	Indicates that the device finished core programming in Configuration via Protocol mode. If this option is turned off, the CvP_CONFDONE pin is disabled when the device operates in user mode and is available as a user I/O pin. *Note:* Not available for Agilex 7 or Stratix 10 devices.
Enable open drain on CvP_CONFDONE pin	Enables the open drain on the CvP_CONFDONE pin. *Note:* Not available for Agilex 7 or Stratix 10 devices.

Table 25. Partial Reconfiguration Options

Specifies generation of secondary programming files that partial reconfiguration requires. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Partial Reconfiguration**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Enable partial reconfiguration pins	Allows you to enable the PR_REQUEST, PR_READY, PR_ERROR, PR_DONE, DCLK, and DATA[31..0] pins. These pins are needed to support partial reconfiguration (PR) with an external host. An external host uses the PR_REQUEST pin to request partial reconfiguration, the PR_READY pin to determine if the device is ready to receive programming data, the PR_ERROR pin to externally monitor programming errors, and the PR_DONE pin to indicate the device finished programming. If this option is turned off, these pins are not available as PR pins when the device operates in user mode and the dual-purpose programming pins are available as user I/O pins. *Note:* Not available for Agilex 7 or Stratix 10 devices.
Enable open drain on partial reconfiguration pins	Allows you to specify an open drain on the PR_READY, PR_ERROR, PR_DONE Partial Reconfiguration pins. *Note:* Not available for Agilex 7 or Stratix 10 devices.
Generate Partial-Masked SOF files	Generates a Partial-Masked SRAM Object file (.pmsf) containing both configuration data and region definitions that can be used to re-configure a device region. If this option is turned on, the .pmsf generates instead of a Mask Settings file (.msf).
Generate Partial Reconfiguration RBF	Generates a Partial Reconfiguration Raw Binary File (.rbf) containing configuration data that an intelligent external controller can use to reconfigure the portion of target device.

Table 26. Power Management & VID Options

For Stratix 10 and Agilex 7 devices only, specifies options for managing power, such as the bus speed mode and the address of the voltage regulator when in PMBus Master mode. To access, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Power Management & VID Options**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Bus speed mode	Specifies the bus speed mode (for example, **100 KHz** or **400 KHz**) in PMBus Master mode.
Slave device type	Specifies the slave device type when the target FPGA device is in PMBus master mode. Available options are **ED8401**, **EM21XX**, **EM22XX**, **ISL82XX**, **ISL69260**, **LTM4677**, and **Other**.
Device address in PMBus Slave mode	Specifies the starting 00 device address when in PMBus Slave mode.
PMBus device 0 slave address through **PMBus device 7 slave address**	Specifies 7-bit hexadecimal value (without leading prefix 0x). For example, 7F for the slave address of a voltage regulator when in PMBus Master mode. You must specify a non-zero address.
Voltage output format	Specifies the **Auto discovery**, **Direct format**, or **Linear format** output voltage format when in PMBus Master mode

continued...

Option	Description
Direct format coefficient (m,b,R)	Specifies direct format coefficient m, b, or R when in PMBus Master mode. Signed integer between -32768 and 32767. Coefficient m is the slope coefficient. Coefficient b is the offset. Coefficient R is the exponent. Refer to the PMBus device manufacturer product documentation for these values. You must set this parameter when output voltage format of PMBus device is **Direct format** or **Auto discovery** format. You must specify a non-zero address when the output voltage format of PMBus device is in **Direct format**.
Linear format N	Specifies linear format N when in PMBus Master mode. Signed integer between -16 and 15. This is the exponent for the mantissa for the output voltage related command when VOUT format is set to **Linear format**. Refer to the PMBus device manufacturer product documentation for these values. You must specify a non-zero value for **Linear format**.
Translated voltage value unit	Specifies the **Volts** or **Millivolts** output voltage format when in PMBus Master mode.
Enable PAGE command	The FPGA PMBus master uses PAGE command to set all output channels on registered regulator modules to respond to VOUT_COMMAND.
More Options	Opens the **Advanced Power Management & VID Options** dialog box for specifying the following additional options: • **Enable status_byte for polling**—Enables the device to query the voltage regulator status via STATUS WORD command. If any errors are found, the SEU_ERROR pin is asserted. The Error Message Queue (EMQ) includes the complete details about the error. For instructions about retrieving the EMQ, refer to the *SEU Mitigation User Guide* for your device. • **Disable VID for debug purpose only**—Use this option for debug purpose only. When you enable this option, you must set the device operating voltage to 0.8 V. VID is disabled, and device performance and functionality are not guaranteed. • **Diagnostic Boot**—Performs additional checks of the voltage regulator's configuration and operation. *Note:* This feature adds to the configuration time, so enable this option only during board bring-up operations.

Table 27. Assembler Security Settings

For Stratix 10 devices, specifies settings for programming bitstream authentication, encryption, scrambling, and other eFuse enabled security options. To access these settings, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Security**. Disabled options are unavailable for the current device or configuration mode.

Option	Description
Quartus Key File	Specifies the first level signature chain file (.qky) that you generate. This chain includes the root key (.pem) and one or more design signing keys (.pem) required to sign the bitstream and allow access to the FPGA when using authentication or encryption.
Encryption key storage select	Specifies the location that stores the .qek key file. You can select either **Battery Backup RAM** or **eFuses** for storage.
Encryption update ratio	Specifies the ratio of configuration bits compared to the number of key updates required for bitstream decryption. You can select either **31:1** (the key must change 1 time every 31 bits) or **Disabled** (no update required). Encryption supports up to 20 intermediate keys.
Enable scrambling	Scrambles the configuration bitstream.
More Options	Opens the **More Security Options** dialog box for specifying additional physical security options.

Table 28. Configuration PIN Dialog Box

For Stratix 10 devices, allows you to enable or disable specific configuration pins. For example, you can enable the CvP_CONFDONE pin, which indicates that the device finished core programming in Configuration via Protocol mode. To access these settings, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Configuration Pin Options**. Disabled options are unavailable for the current device or configuration mode.

Option	Values	Description
USE PWRMGT_SCL output	**SDM_1O0|SDM_IO14**	This is a required PMBus interface for the power management when the VID operation mode is the PMBus Master or PMBus Slave mode. Disable this pin for a non-SmartVID device. Intel recommends using the SDM_IO14 pin for this function.
Use PWRMGT_SDA output	**SDM_1O11|SDM_1O12| SDM_1O16**	This is a required PMBus interface for the power management when the VID operation mode is the PMBus Master or PMBus Slave mode. Disable this pin for a non-SmartVID device. Intel recommends using the SDM_IO11 pin for this function.
Use PWRMGT_ALERT output	**SDM_1O0|SDM_1O12**	This is a required PMBus interface for the power management that is used only in the PMBus Slave mode. Disable this pin for a non-SmartVID device. Intel recommends using the SDM_IO12 pin for this function.
USE CONF_DONE output	**SDM_100, SDM_1010 - SDM_1016**	Implement CONF_DONE using appropriate configuration pin resource.
USE INIT_DONE output	**SDM_100, SDM_1010 - SDM_1016**	Enables the INIT_DONE pin, which allows you to externally monitor when initialization is completed and the device is in user mode. If this option is turned off, the INIT_DONE pin is disabled when the device operates in user mode and is available as a user I/O pin.
USE CVPCONF_DONE output	**SDM_100, SDM_1010 - SDM_1016**	Enables the CVP_CONFDONE pin, which indicates that the device finished core programming in Configuration via Protocol mode. If this option is turned off, the CVP_CONFDONE pin is disabled when the device operates in user mode and is available as a user I/O pin.
USE SEU_ERROR output	**SDM_100, SDM_1010 - SDM_1016**	Enables the SEU_ERROR pin for use in single event upset error detection.
USE UIB CATTRIP output	**SDM_100, SDM_1010 - SDM_1016**	Enables UIB_CATTRIP output to indicate an extreme over-temperature conditioning resulted from UIB usage.
USE HPS cold nreset	**SDM_100, SDM_1010 - SDM_1016**	An optional reset input that cold resets only the HPS and is configured for bidirectional operation.
Direct to factory image	**SDM_100, SDM_1010 - SDM_1016**	If this pin asserted then device loads the factory image as the first image after boot without attempting to load any application image.
USE DATA LOCK output	**SDM_100, SDM_1010 - SDM_1016**	Output to indicate DIBs on both die in the same package is ready for data transfer.

Related Information

Enabling Bitstream Authentication (Programming File Generator) on page 20

2.9.2. More Security Options Dialog Box

Table 29. More Security Options Dialog Box

For Stratix 10 devices, specifies additional configuration bitstream physical security settings. To access these settings, click **Assignments ➤ Device ➤ Device and Pin Options ➤ Security ➤ More Settings** button. Disabled options are unavailable for the current device or configuration mode.

Option	Description	Values
Disable JTAG	Disables JTAG command and configuration of the device. Setting this eliminates JTAG as mode of attack, but also eliminates boundary scan functionality.	• **Off**—inactive • **On**—active until wipe of containing design • **On sticky**—active until next POR • **On check**—checks for corresponding blown fuse
Force SDM clock to internal oscillator	Disables an external clock source for the SDM. The SDM must use the internal oscillator. Using an internal oscillator is more secure than allowing an external clock source for configuration.	
Force encryption key update	Specifies that the encryption key must update by the frequency that you specify for the **Encryption update ratio** option. The default ration value is 31:1. Encryption supports up to 20 intermediate keys.	
Disable virtual eFuses	Disables the eFuse virtual programming capability.	
Lock security eFuses	Causes eFuse failure if the eFuse CRC does not match the calculated value.	
Disable HPS debug	Disables debugging through the JTAG interface to access the HPS.	
Disable encryption key in eFuses	Specifies that the device cannot use an AES key stored in eFuses. Rather, you can provides an extra level of security by storing the AES key in BBRAM.	
Disable encryption key in BBRAM	Specifies that the device cannot use AES key stored in BBRAM. Rather, you can provides an extra level of security when you store the AES key in eFuses.	

2.9.3. Output Files Tab Settings (Programming File Generator)

The **Output Files** tab allows you to specify the type of secondary programming file that you want to generate (output) with the **Programming File Generator**. The **Programming File Generator** converts a primary programming file (for example, `.sof`) into a programming file for alternative programming methods (for example, a `.jic` for flash programming). The **Output Files** tab and options change dynamically according to your selections.

The following output file options are available:

Table 30. Output File Options

Setting	Description
Device family	Specifies the FPGA device family you are targeting for configuration. **Programming File Generator** supports only Agilex 7, Stratix 10, MAX 10, and Cyclone 10 LP devices.
Configuration mode	Specifies the method of FPGA configuration, such as **Active Serial x4**, **AVST x8**, **AVST x16**, or **AVST x32**. Generic Flash Programmer supports only **Active Serial x4**.
Output directory and **Name**	Specifies the name and location of the file you generate. By default, this location is in the top-level project directory.
File Types	Allows you to enable the type of secondary programming file that you want to generate. Generic Flash Programmer supports only **JTAG Indirect Configuration File (.jic)**. The available options include: • **JTAG Indirect Configuration File (.jic)** • **Programmer Object File (.pof)** • **Raw Binary File for CvP Core Configuration (.rbf)** • **Raw Binary File for HPS Core Configuration (.rbf)** • **Raw Binary File for Partial Reconfiguration (.rbf)** • **Raw Programming Data File (.rpd)**

2.9.4. Input Files Tab Settings (Programming File Generator)

The **Input Files** tab allows you to specify the `.sof`, `.pmsf`, or `.rbf` file that contains the configuration bitstream data required to generate one or more secondary programming files. The **Input Files** tab and options change dynamically, according to your **Output Files** tab selections.

The following input file settings are available:

Table 31. Input File Settings

Setting	Description
Add Bitstream	Click this button to specify a `.sof`, `.pmsf`, or `.rbf` as input for generation of the secondary programming file you select in **Output Files**. Depending on the target device, the Quartus Prime software may allow you to add multiple SOF files.
Add Raw Data	Click this button to specify a `.hex` or `.bin` file that contains raw programming data as input for generation of the secondary programming file you select in **Output Files**.
Remove	Removes the file you select from the **Input Files** tab.
Properties	Displays the properties of the item you select in the **Input Files** tab.

Related Information

Enabling Bitstream Encryption (Programming File Generator) on page 23

2.9.5. Bitstream Co-Signing Security Settings (Programming File Generator)

Table 32. Input File Properties Dialog Box (Programming File Generator)

Allows you to specify options for bitstream authentication, co-signing, and encryption security. To access, select an `.sof` or `.rbf` in the **Input files** tab in the **Programming File Generator**, and click **Properties**.

Option	Description
Bootloader	Specifies an ASCII text file in Intel hexadecimal format that contains configuration data for programming a parallel data source, such as a configuration device or a mass storage device. The parallel data source in turn configures an SRAM-based Intel device
Enable signing tool	Enables the signing tool that checks for a required Privacy Enhanced Mail Certificates file (`.pem`) for the **Private key file**, and a Quartus Co-Signed Firmware file (`.zip`) for the **Co-signed firmware** option.
Private key file	Specifies the private `.pem` file required to sign the configuration bitstream when using the signing tool. If your `.pem` is password-protected, you are prompted to enter the password.
Co-signed firmware	Specifies the firmware source (`.zip`) required to include the signed firmware in the configuration bitstream.
Finalize encryption	Finalizes the configuration bitstream encryption.
Encryption key file	Specifies the Encryption Key File (`.qek`) required to decrypt the configuration bitstream file.

2.9.6. Configuration Device Tab Settings

The **Configuration Device** tab allows you to specify the properties of an existing or new flash memory device that you want to program. Click **Add Device** to select a programming template for a predefined flash memory, or to click **<<new device>>** and then define a new flash memory device.

The following settings are available:

Table 33. Configuration Device Tab Settings

Option	Description
Device name	Specify a unique name for the flash not already listed in the **Name** column. The **Name** must not contain any empty string (space) or special characters (except "_").
Device ID	Specify the 3-byte ID that the Programmer Auto-Detect operation uses to detect the flash programming device, such as `0x20 0xBB 0x21`.
Device I/O voltage	Specify **1.8V** or **3.0/3.3V** to match your memory device specification.
Device density	Select the total density that corresponds with your flash memory device size.
Total device die	Specify the total number of die for a stacked device (where applicable).
Single I/O mode dummy clock	Specify the Fast Read dummy clock cycle for flash device in single I/O protocol. The programming file generation uses this setting to determine if the configuration requires bit shifting to compensate for the actual dummy clock cycle during Active Serial configuration.
Quad I/O mode dummy clock	Specify the Fast Read dummy clock cycle for flash device in Quad I/O protocol. The programming file generation uses this setting to determine if the configuration requires bit shifting to compensate for the actual dummy clock cycle during Active Serial configuration.
Custom database directory	Specifies the location of the `.xml` file that preserves a flash memory device definition.

continued...

Option	Description
	Note: When you specify a non-default folder for the **Custom database directory** location, place the `.sof` and `.jic` files in the same folder as the `.xml` file to avoid missing a defined flash database or corruption of the `.jic` file.

2.9.7. Add Partition Dialog Box (Programming File Generator)

To open in the **Programming File Generator**, click the **Configuration Device** tab, select a device from the list, and click **Add Partition**.

Allows you to specify the attributes of a new partition. The following settings are available:

Table 34. Add Partition Dialog Box Settings

Setting	Description
Name	Name that you give to the partition.
Input file	Input file to program into the flash partition.
Page	Configuration devices can store multiple configuration bitstreams in flash memory, called pages. CFI configuration devices can store up to eight configuration bitstreams. Hyperflex devices can store up to four configuration bitstreams, including the factory image. In Hyperflex devices, with the remote system update feature enabled, **Page** represents the parity.
Address Mode	The options are: • **Auto**—automatically allocates a block in the flash device to store the data. • **Block**—specify the start and end address of the flash partition. • **Start**—specify the start address of the partition. The tool assigns the end address of the partition based on the input data size.
Start address	Specifies the start address of the partition. Only enabled when **Address Mode** is **Block** or **Start**.
End address	Specifies the end address of the partition. Only enabled when **Address Mode** is **Block**.

2.9.8. Add Filesystem Dialog Box (Programming File Generator)

To open in the **Programming File Generator**, click the **Configuration Device** tab, select a device from the list, and click **Add Filesystem**.

Allows you to specify the attributes of a new file system partition. The following settings are available:

Table 35. Add Filesystem Dialog Box Settings

Setting	Description
Name	Name given to the file system. This value is fixed and set to LITTLEFS. You cannot change this value.
Input file	Input ZIP file that contains files to write to the file system partition.
Address Mode	The options are as follows:

continued...

Setting	Description
	• **Highest** Allocate the start address of the file system partition at the highest address of the flash memory device. • **Start** Allocate the start address of the file system partition at the start address specified in the **Start address** field. • **Auto** Allocate the start address for the file system partition automatically.
Start address	Specifies the start address of the file system. Enabled only when **Address Mode** is **Start**.
Size (MB)	Specifies the size of the file system partition in MB. The default file system size is 1 MB. Enabled only when **Address Mode** is **Highest** or **Start**.

2.9.9. Convert Programming File Dialog Box

Allows you to convert or combine one or more secondary programming files that support alternative device configuration schemes, such as flash programming, partial reconfiguration, or remote system update.

Table 36. Convert Programming File Dialog Box Settings

Setting	Description
Programming file type	Allows you to specify a secondary programming file format for conversion of a primary programming file. The Generic Flash Programmer supports only the `.jic` file type.
Configuration device	Allows you to select a predefined or define a new configuration device. Click the (**...**) button to define a new device and programming flow.
Mode	Allows you to select the method of device configuration. The Generic Flash Programmer supports only the **Active Serial** or **Active Serial x4** modes.
Output file	Specifies the location of the files that **Convert Programming File** generates. By default this location is the top-level project directory.
Input files to convert	Specifies one or more primary programming files for conversion or combination into one or more secondary programming files for alternative programming methods.

2.9.10. Compression and Encryption Settings (Convert Programming File)

The compression and encryption settings allow you to specify options for compression and encryption key security for the device configuration SRAM Object File (`.sof`). To access these settings, select the `.sof` in the **Input files to convert** list in the **Convert Programming File** dialog box, and click **Properties**.

Table 37. SOF File Properties: Bitstream Encryption Dialog Box (Convert Programming Files)

Allows you to specify options for compression and encryption key security for the device configuration SRAM Object File (`.sof`). To access, select an `.sof` in the **Input files to convert** list in the **Convert Programming Files** dialog box, and click **Properties**.

Option	Description
Compression	Applies compression to the bitstream to reduce the size of your programming file. The Quartus Prime Assembler can generate a compressed bitstream image that reduces configuration file size by 30% to 55% (depending on the design). The FPGA device receives the compressed configuration bitstream, and then can decompress the data in real-time during configuration. This option is unavailable whenever **Generate encrypted bitstream** is enabled.
Enable decompression during partial reconfiguration	Enables the option bit for bitstream decompression during Partial Reconfiguration.
Generate encrypted bitstream	Generates an encrypted bitstream configuration image. You then generate and specify an encryption key file (`.ekp`) for device configuration. This option is unavailable whenever **Compression** is enabled.
Enable volatile security key	Allows you to encrypt the `.sof` file with volatile (enabled) or non-volatile (disabled) security key.
Generate encryption lock file	Specifies the name of the encryption lock file (`.elk`) that **Convert Programming Files** generates.
Generate key programming file	Specifies the name of the key programming file (`.key`) that **Convert Programming Files** generates.
Use key file	• **Key 1 file**—specifies the name of Key 1 `.key` file. • **Key 2 file**—specifies the name of Key 2 `.key` file.
Key entry	Specifies the keys for bitstream decryption.
Security options	The following options allow you to enable or disable features that impact device security for the configuration bitstream. • **Disable partial reconfiguration**—disables use of partial reconfiguration for the bitstream. • **Disable key-related JTAG instructions**—disables use of key-related JTAG instructions for the bitstream. • **Disable other extended JTAG instructions**—disables use of other JTAG instructions for the bitstream. • **Force the external JTAG pins into BYPASS mode**—forces the external JTAG pins into BYPASS mode. You can specify **Off**, **Turns On Until the Next Full Configuration**, **Turns on until the next Power-On-Reset event**, **Turns on by blowing the corresponding fuses**,
Design Security Feature Disclaimer	Acknowledges required acceptance of Design Security Disclaimer.

2.9.11. SOF Data Properties Dialog Box (Convert Programming File)

Allows you to define flash memory pages that store configuration data. To access from the **Convert Programming File** dialog box, click the **SOF Data** item and click the **Properties** button.

The following settings are available:

Table 38. SOF Data Properties Dialog Box Settings

Setting	Description
Pages	Configuration devices can store multiple configuration bitstreams in flash memory, called pages. CFI configuration devices can store up to eight configuration bitstreams. Some Intel FPGA devices can store multiple configuration bitstreams, including the factory image.
Address mode for selected pages	The options are: • **Auto**—automatically allocates a block in the flash device to store the data. • **Block**—specify the start and end address of the flash partition. • **Start**—specify the start address of the partition. The tool assigns the end address of the partition based on the input data size.
Start address	Specifies the start address of the partition. Only enabled when **Address Mode** is **Block** or **Start**.
End address	Specifies the end address of the partition. Only enabled when **Address Mode** is **Block**.

2.9.12. Select Devices (Flash Loader) Dialog Box

Allows you to select the device that controls loading of configuration data into a flash memory device. To access from the **Programming File Generator**, click the **Select** button for **Flash loader** in the **Configuration Device** tab. To access from the **Convert Programming File** dialog box, select the **Flash Loader** item and click **Add Device**.

The following settings are available:

Table 39. Flash Loader (Select Devices Dialog Box)

Option	Description
Device family	Specifies the family of the flash loader device.
Device name	Specifies the name of the flash loader device.

2.10. Scripting Support

In addition to the Quartus Prime Programmer GUI, you can access programmer functionality from the command line and from scripts with the Quartus Prime command-line executable `quartus_pgm.exe` (or `quartus_pgm` in Linux).

The following command programs a device from a Microsoft* Windows* command line:

```
quartus_pgm –c usbblasterII –m jtag –o bpv;design.pof
```

Where:

-c usbblasterII specifies the Intel FPGA Download Cable II

-m jtag specifies the JTAG programming mode

-o bpv represents the blank-check, program, and verify operations

design.pof	represents the `.pof` containing the design logic

The Programmer automatically executes the erase operation before programming the device.

In a Linux* terminal terminal window, use:

```
quartus_pgm –c usbblasterII –m jtag –o bpv\;design.pof
```

The following examples shows how to erase flash memory that is connected to the FPGA through an active serial interface from a Microsoft Windows command line:

```
quartus_pgm -c usbblasterII -m jtag -o ri;design.jic@1
```

Where:

-c usbblasterII	specifies the Intel FPGA Download Cable II
-m jtag	specifies the JTAG programming mode
-o ri	represents the serial flash loader program and erase operations
design.jic	represents the JTAG indirect configuration file (`.jic`)
@1	specifies the device number in the JTAG chain on which these operations are performed

In a Linux terminal terminal window, use:

```
quartus_pgm -c usbblasterII -m jtag -o ri\;design.jic@1
```

Quartus Prime Scripting
In *Quartus Prime Help*

2.10.1. The jtagconfig Debugging Tool

You can use the `jtagconfig` command-line utility to check the devices in a JTAG chain and the user-defined devices. The `jtagconfig` command-line utility is similar to the auto detect operation in the Quartus Prime Programmer.

For more information about the `jtagconfig` utility, use the help available at the command prompt:

```
jtagconfig [–h | --help]
```

Note: The help switch does not reference the `-n` switch. The `jtagconfig -n` command shows each node for each JTAG device.

2.11. Using the Quartus Prime Programmer Revision History

Table 40. Document Revision History

Date	Quartus Prime Version	Changes
2024.04.01	24.1	• Made the following changes in *Device & Pin Options Dialog Box*: — Added ISL69260 to the list of slave device types and additional options to the *Power Management & VID Options* table. — Added Agilex 5 device-related options to the *Error Detection CRC Options* table.
2023.04.03	23.1	• Updated product family name to "Intel Agilex 7."
2022.09.26	22.3	• Added "Add Filesystem Dialog Box". • Removed footnotes saying that security features are not available for Agilex 7 devices. For details about security features for Agilex 7 devices, refer to the *Agilex 7 Device Security User Guide*.
2021.07.21	21.2	• Updated "JTAG Chain Debugger Tool". • Added "JTAG Chain Integrity". • Added "JTAG Chain Debugging".
2021.06.21	21.2	• Updated "Scripting Support" with an additional example.
2020.05.26	19.4.0	• Corrected descriptions of "Bus Speed Mode" and "Slave Device Type" power options.
2019.09.30	19.3.0	• Updated "Device & pin Options" topic to reflect new Security settings tab. • Updated "Configuration Device Tab" topic to reflect Custom database directory option. • Referenced compilation support for Agilex 7 devices. • Added "More Security Options Dialog Box" topic. • Added new "Bitstream Co-Signing Security Settings" topic. • Updated "SOF File Properties: Bitstream Encryption Dialog Box" topic. • Added new steps to "Full Erase of Flash Memory Sectors" topic.
2019.06.10	19.1.0	• Updated "Programming with Flash Loaders" topic to reflect new Generic Flash Programmer. • Removed references to obsolete 32-bit stand-alone Programmer. • Added "Erasing Flash Memory Sectors" topic describing complete erase of flash memory. • Added new "Programmer Settings Reference" section containing the following new GUI reference topics: — "Device & Pin Options Dialog Box" — "Input Files Tab Settings (Programming File Generator)" — "Output Files Tab Settings (Programming File Generator)" — "Configuration Device Tab Settings (Programming File Generator)" — "Add Partition Dialog Box (Programming File Generator)" — "Bitstream Compression, Authentication, and Encryption Settings (Programming File Generator)" — "Convert Programming Files Dialog Box" — "Bitstream Compression and Encryption Settings (Convert Programming File)" — "SOF Data Properties Dialog Box" — "Select Devices (Flash Loader) Dialog Box"
2019.04.01	19.1.0	• Added new "Using PR Bitstream Security Verification" topic. • Added new "Basic Device Configuration Steps" topic. • Added new "Programming and Configuration Modes" topic.

continued...

Date	Quartus Prime Version	Changes
		• Retitled and reorganized topics to improve flow of information. • Added enhanced diagram of Programmer to "Quartus Prime Programmer" topic. • Updated screenshots.
2018.10.09	18.1.0	• Created topic: *Stand-Alone Programmer Memory Limitations* from content in topic: *Stand-Alone Programmer*. • Removed outdated support information.
2018.08.07	18.0.0	Reverted document title to *Programmer User Guide: Quartus Prime Pro Edition*.
2018.06.27	18.0.0	• Moved information about programming file generator to new chapter: *Generating Programming Files*.
2018.05.07	18.0.0	• First release as part of the stand-alone *Programmer User Guide*
2017.05.08	17.0.0	• Added Project Hash feature.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2015.11.02	15.1.0	Changed instances of Quartus II to Quartus Prime software.
2015.05.04	15.0.0	Added Conversion Setup File (.cof) description and example.
December 2014	14.1.0	Updated the Scripting Support section to include a Linux command to program a device.
June 2014	14.0.0	• Added Running JTAG Daemon. • Removed Cyclone III and Stratix III devices references. • Removed MegaWizard Plug-In Manager references. • Updated Secondary Programming Files section to add notes about the Quartus II Programmer support for **.rbf** files.
November 2013	13.1.0	• Converted to DITA format. • Added JTAG Debug Mode for Partial Reconfiguration and Configuring Partial Reconfiguration Bitstream in JTAG Debug Mode sections.
November 2012	12.1.0	• Updated Table 18–3 on page 18–6, and Table 18–4 on page 18–8. • Added "Converting Programming Files for Partial Reconfiguration" on page 18–10, "Generating .pmsf using a .msf and a .sof" on page 18–10, "Generating .rbf for Partial Reconfiguration Using a .pmsf" on page 18–12, "Enable Decompression during Partial Reconfiguration Option" on page 18–14 • Updated "Scripting Support" on page 18–15.
June 2012	12.0.0	• Updated Table 18–5 on page 18–8. • Updated "Quartus II Programmer GUI" on page 18–3.
November 2011	11.1.0	• Updated "Configuration Modes" on page 18–5. • Added "Optional Programming or Configuration Files" on page 18–6. • Updated Table 18–2 on page 18–5.
May 2011	11.0.0	• Added links to Quartus II Help. • Updated "Hardware Setup" on page 21–4 and "JTAG Chain Debugger Tool" on page 21–4.
December 2010	10.1.0	• Changed to new document template. • Updated "JTAG Chain Debugger Example" on page 20–4. • Added links to Quartus II Help. • Reorganized chapter.

continued...

Date	Quartus Prime Version	Changes
July 2010	10.0.0	• Added links to Quartus II Help. • Deleted screen shots.
November 2009	9.1.0	No change to content.
March 2009	9.0.0	• Added a row to Table 21–4. • Changed references from "JTAG Chain Debug" to "JTAG Chain Debugger". • Updated figures.

3. Using the HPS Flash Programmer

The Quartus Prime software and Quartus Prime Programmer include the hard processor system (HPS) flash programmer. Hardware designs, such as HPS, incorporate flash memory on the board to store FPGA configuration data or HPS program data. The HPS flash programmer programs the data into a flash memory device connected to an Intel FPGA SoC. The programmer sends file contents over a download cable, such as the Intel FPGA Download Cable II, to the HPS and instructs the HPS to write the data to the flash memory.

The HPS flash programmer programs the following content types to flash memory:

- HPS software executable files — Many systems use flash memory to store non-volatile program code or firmware. HPS systems can boot from flash memory.

  Note: The HPS Flash Programmer is mainly intended to be used for programming the Preloader image to QSPI or NAND flash. Because of the low speed of operation, it is not recommended to be used for programming large files.
- FPGA configuration data — At system power-up, the FPGA configuration controller on the board or HPS read FPGA configuration data from the flash memory to program the FPGA. The configuration controller or HPS may be able to choose between multiple FPGA configuration files stored in flash memory.
- Other arbitrary data files — The HPS flash programmer programs a binary file to any location in a flash memory for any purpose. For example, a HPS program can use this data as a coefficient table or a sine lookup table.

The HPS flash programmer programs the following memory types:

- Quad serial peripheral interface (QSPI) Flash
- Open NAND Flash Interface (ONFI) compliant NAND Flash

3.1. Supported Devices

Table 41. HPS Flash Programmer-supported Devices

	Cyclone V SoC, Arria V SoC	Arria 10 SoC	Stratix 10 SoC, Agilex 7 F-Series/I-Series/M-Series SoC	Agilex 5 E-Series/D-Series SoC
HPS Flash Programmer	Supported	Supported	Not Supported *	Not Supported *

Note: For Stratix 10 SoC, Agilex 7 SoC, or Agilex 5 SoC devices, you must program the flash connected to HPS. You have the following options:

- Use a bus switch to route the QSPI signals to an external master that does the programming.
- Use software running on HPS to do the programming. For example, you can load U-Boot with an Arm* debugger or System Console, and then use it to program the flash.

Note: On Stratix 10 SoC, Agilex 7 SoC, or Agilex 5 SoC devices, the HPS can access the QSPI flash memory connected to SDM. This flash is programmed using the Quartus Prime Programmer tool that is part of the Quartus Prime Pro Edition software. For additional information about the use of the Quartus Prime Programmer, refer to your device's boot user guides.

- HPS SoC Boot Guide - Cyclone V SoC Development Kit

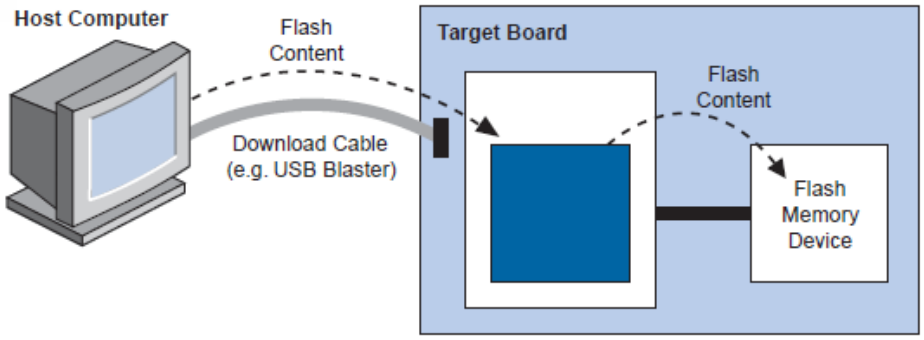
3.2. HPS Flash Programmer Command-Line Utility

Run the HPS flash programmer from the command line. The HPS flash programmer is located in the <*Quartus Prime installation directory*>/quartus/bin directory.

3.3. How the HPS Flash Programmer Works

The HPS flash programmer is divided into a host and a target. The host portion runs on your computer and sends flash programming files and programming instructions over a download cable to the target. The target portion is the HPS in the SoC. The target accepts the programming data flash content and required information about the target flash memory device sent by the host. The target writes the data to the flash memory device.

Figure 38. HPS Flash Programmer



The HPS flash programmer determines the type of flash to program by sampling the boot select (BSEL) pins during cold reset; you do not need to specify the type of flash to program.

3.4. Using the Flash Programmer from the Command Line

3.4.1. HPS Flash Programmer

The HPS flash programmer utility can erase, blank-check, program, verify, and examine the flash. The utility accepts a Binary File with a required "**.bin**" extension.

The HPS flash programmer command-line syntax is:

```
quartus_hps <options> <file.bin>
```

Note: The HPS flash programmer uses byte addressing.

Table 42. HPS Flash Programmer Parameters

Option	Short Option	Required	Description
`--addr`	`-a`	Yes (if the start address is not 0)	This option specifies the start address of the operation to be performed.
`--cable`	`-c`	Yes	This option specifies what download cable to use. To obtain the list of programming cables, run the command "jtagconfig". It lists the available cables, like in the following example: `jtagconfig` • Intel FPGA Download Cable [USB-0] • Intel FPGA Download Cable [USB-1] • Intel FPGA Download Cable [USB-2] The "`-c`" parameter can be the number of the programming cable, or its name. The following are valid examples for the above case: • `-c 1` • `-c` "Intel FPGA Download Cable [USB-2]"
`--device`	`-d`	Yes (if there are multiple HPS devices in the chain)	This option specifies the index of the HPS device. The tool automatically detects the chain and determine the position of the HPS device; however, if there are multiple HPS devices in the chain, the targeted device index must be specified.
`--boot`	N/A	Yes	Option to reconfigure the HPS IOCSR and PINMUX before starting flash programming. For the Quartus Prime HPS Flash Programmer options: • Warm/cold reset HPS (BootROM) so that BootROM can reconfigure the setting. FPGA (for Arria 10) is `nconfig`. • Explicitly configure dedicated I/O and PINMUX Available options: • 1 - Set Breakpoint to halt CPU, warm reset HPS [not recommended][6] • 2 - Set Watchpoint to halt CPU, warm reset HPS[7]

continued...

[6] Warm reset HPS for BootROM to configure dedicated IO and PINMUX, and use a breakpoint to halt CPU.

Option	Short Option	Required	Description
			• 3 - Explicitly configure dedicated IO and PINMUX(8) • 16 - Cold reset HPS(9) Cyclone V and Arria 10 support values: 1, 2 and 16. Arria 10 supports values: 2, 3 and 16 *Note:* For the first three options, add up integer of 16, so that the HPS cold reset is performed Available options for a cold reset before the flow: • 17 - Cold reset HPS + breakpoint(10) • 18 - Cold reset HPS + watchpoint(11) • 19 - Cold reset HPS + configure dedicated IO and PINMUX(12)
`--exit_xip`	N/A	Yes (if the QSPI flash device has been put into XIP mode)	This option exits the QSPI flash device from XIP mode. A non-zero value has to be specified for the argument. For example, `quartus_hps -c <cable> -o <operation> --exit_xip=0x80`.
`--operation`	`-o`	Yes	This option specifies the operation to be performed. The following operations are supported: • I—Read IDCODE of SOC device and discover Access Port • S—Read Silicon ID of the flash • E—Erase flash • B—Blank-check flash • P—Program flash • V—Verify flash • EB—Erase and blank-check flash • BP—Program <*BlankCheck*> flash • PV—Program and verify flash • BPV—Program (blank-check) and verify flash • X—Examine flash *Note:* The program begins with erasing the flash operation before programming the flash by default.
`--size`	`-s`	No	This option specifies the number of bytes of data to be performed by the operation. `size` is optional.

continued...

(7) Warm reset HPS for BootROM to configure dedicated IO and PINMUX, and use a watchpoint to halt CPU.

(8) Explicitly configure dedicated IO and PINMUX.

(9) Bit-wise on top of the flow, if you set the bit, the tool will perform cold reset first

(10) Cold reset HPS for BootROM to configure dedicated IO and PINMUX, and use a breakpoint to halt CPU.

(11) Cold reset HPS for BootROM to configure dedicated IO and PINMUX, and use a watchpoint to halt CPU.

(12) Cold reset HPS, then explicitly configure dedicated IO and PINMUX.

Option	Short Option	Required	Description
Note: The following options: `repeat` and `interval` must be used together and are optional. The HPS BOOT flow supports up to four images where each image is identical. These options duplicate the operation data; therefore you do not need embedded software to create a large file containing duplicate images.			
`--repeat`	`-t`	No	`repeat`—specifies the number of duplicate images for the operation to perform.
`--interval`	`-i`	No	`interval`—specifies the repeated address. The default value is 64 kilobytes (KB).

3.4.2. HPS Flash Programmer Command Line Examples

Type `quartus_hps --help` to obtain information about usage. You can also type `quartus_hps --help=<option>` to obtain more details about each option. For example "quartus_hps --help=o".

Example 2. Program File to Address 0 of Flash

`quartus_hps –c 1 –o P input.bin` programs the input file (**input.bin**) into the flash, starting at flash address 0 using a cable 1.

Example 3. Program First 500 Bytes of File to Flash (Decimal)

`quartus_hps –c 1 –o PV –a 1024 –s 500 input.bin` programs the first 500 bytes of the input file (**input.bin**) into the flash, starting at flash address 1024, followed by a verification using a cable 1.

Note: Without the prefix "0x" for the flash address, the tool assumes it is decimal.

Example 4. Program First 500 Bytes of File to Flash (Hexadecimal)

`quartus_hps –c 1 –o PV –a 0x400 –s 500 input.bin` programs the first 500 bytes of the input file (**input.bin**) into the flash, starting at flash address 1024, followed by a verification using a cable *1*.

Note: With the prefix 0x, the tool assumes it is hexadecimal.

Example 5. Program File to Flash Repeating Twice at Every 1 MB

`quartus_hps –c 1 –o BPV –t 2 –i 0x100000 input.bin` programs the input file (**input.bin**) into the flash, using a cable 1. The operation repeats itself twice at every 1 megabyte (MB) of the flash address. Before the program operation, the tool ensures the flash is blank. After the program operation, the tool verifies the data programmed.

Example 6. Erase Flash on the Flash Addresses

`quartus_hps –c 1 –o EB input.bin` erases the flash on the flash addresses where the input file (**input.bin**) resides, followed by a blank-check using a cable 1.

Example 7. Erase Full Chip

`quartus_hps –c 1 –o E` erases the full chip, using a cable 1. When no input file (**input.bin**) is specified, it erases all the flash contents.

Example 8. Erase Specified Memory Contents of Flash

`quartus_hps –c 1 –o E –a 0x100000 –s 0x400000` erases specified memory contents of the flash. For example, 4 MB worth of memory content residing in the flash address, starting at 1 MB, are erased using a cable 1.

Example 9. Examine Data from Flash

`quartus_hps –c 1 –o X –a 0x98679 –s 56789 output.bin` examines 56789 bytes of data from the flash with a 0x98679 flash start address, using a cable 1.

3.5. Supported Memory Devices

Answers to Top FAQs:

Contents

1. Block-Based Design Flows

The Intel® Quartus® Prime Pro Edition software supports block-based design flows, also known as modular or hierarchical design flows.

You can designate a design block as a design partition in order to reuse the block. A design partition is a logical, named, hierarchical boundary assignment that you can apply to a design instance. Block-based design flows enable the following:

- Design block reuse—export and reuse of design blocks in other projects

You can reuse design blocks with the same periphery configuration, share a synthesized design block with another designer, or replicate placed and routed IP in another project. Design, implement, and verify core or periphery blocks once, and then reuse those blocks multiple times across different projects that use the same device.

1.1. Block-Based Design Terminology

This document refers to the following terms to explain block-based design methods:

Table 1. Block-Based Design Terminology

Term	Description
Black Box File	RTL source file that contains only port and module or entity definitions, without any logic. Include parameters or generics passed to the module or entity to ensure that the configuration matches the implementation in the Consumer project.
Block	Logic that comprises a hierarchical design instance, typically represented by a Verilog module or VHDL entity. You designate a design block as a design partition to empty or export the block.
Consumer	A Consumer can reuse a design partition that a Developer exports as a Partition Database File (`.qdb`) from another project.
Core Partition	A design partition that contains only FPGA resources for the implementation of core logic, such as LUTs, registers, M20K memory blocks, and DSPs. A core partition cannot include periphery resources.
Design Partition	A logical, named, hierarchical boundary assignment that you can apply to a design instance. Creating a partition creates a logical boundary and prevents logic optimization and merging with parent or child partitions. Design partitions facilitate incremental block-based compilation and design block reuse by logically separating instances.
Developer	A Developer creates and exports a design partition as a `.qdb` for use in a Consumer project.
Floorplanning	Planning the physical layout of FPGA device resources. The manual process of assigning the logical design hierarchy and periphery to physical regions in the device and I/O.

continued...

Term	Description
Logic Lock Region Constraints	Constrains the placement and routing of logic to a specific region in the target device. Specify the region origin, height, width, and any of the following options: • **Reserved**—prevents the Fitter from placing non-member logic within the region. • **Core-Only**—applies the constraint only to core logic in the region, and does not include periphery logic in the region. • **Routing Region**—restricts the routing of connections between region members to the specified area. The routing region is non-exclusive. Other resources in the parent or sibling hierarchy levels can use that routing area. You can restrict the routing region to areas equal to or larger than the Logic Lock region, up to the entire chip. The default routing region is the entire chip. • **Size/State**—fixes the size and locks the state of the region. The **Fixed/Locked** option defines a region of fixed size and locked location. The **Auto/Floating** option defines a region with a floating location that automatically sizes to the logic.
Project	The Intel Quartus Prime software organizes the source files, settings, and constraints within a project of one or more revisions. The Intel Quartus Prime Project File (`.qpf`) stores the project name and references each project revision that you create.
Root Partition	The Intel Quartus Prime software automatically creates a top-level "root_partition" with a hierarchy path of |for each project revision. The root partition includes all device periphery resources (such as I/O, HSSIO, memory interfaces, and PCIe*) and associated core resources. You can export and reuse periphery resources by exporting the root partition and reserving a region for subsequent development (the reserved core) by a Consumer.
Snapshot	A snapshot is a view of the design after a compilation stage. The Intel Quartus Prime Compiler generates a snapshot of the compilation database after each compilation stage. You can export a specific snapshot for incremental block-based compilation, design block reuse, and team based designs.

1.2. Block-Based Design Overview

This section provides an overview of design block reuse and incremental block-based compilation flows. Design Block Reuse Flows on page 15 and Incremental Block-Based Compilation Flow on page 25 describe the step-by-step details of these block-based flows.

1.2.1. Design Block Reuse Overview

In design block reuse flows, you export a core or root partition for reuse in another project that targets the same Intel FPGA device family. You can share one of the following compilation snapshots for a partition across projects or with other designers:

- Synthesized snapshot
- Final snapshot

Core partition reuse enables preservation and export of compilation results for a core partition. Reuse of the core partition allows an IP developer to create and optimize an IP once and share it across multiple projects.

Root partition reuse enables preservation and export of compilation results for a top-level (or root) partition that describes the device periphery, along with associated core logic. Reuse of the periphery allows a board developer to create and optimize a platform design with device periphery logic once, and then share that root partition

with other board users who create custom core logic. The periphery resources include all the hardened IP in the device periphery, such as general purpose I/O, PLLs, high-speed transceivers, PCIe, and external memory interfaces.

Team members can work on different partitions separately, and then bring them together later, facilitating a team-based design environment. A team lead integrates the partitions in the system and provides guidance to ensure that each partition uses the appropriate device resource and achieves design requirements during the full design integration. A Developer initially creates and exports a block as a partition in one Intel Quartus Prime project. Subsequently, a *Consumer* reuses the partition in a different project.(1) To avoid resource conflicts, floorplanning is essential when reusing final snapshot partitions.

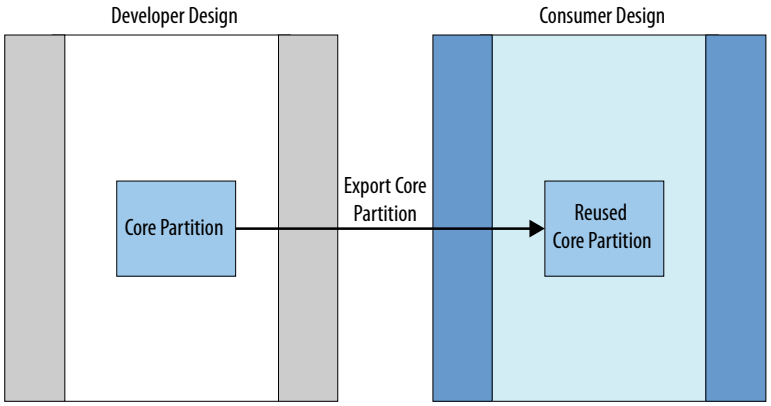
Design Block Reuse Flows on page 15

1.2.1.1. Design Block Reuse Examples

Core Partition Reuse Example

In a typical core partition reuse example, a Developer exports a core partition that already meets design requirements. The Developer optimizes and exports the block, and then the Consumer can simply reuse the block without requiring re-optimization in the Consumer project that targets the same device family.

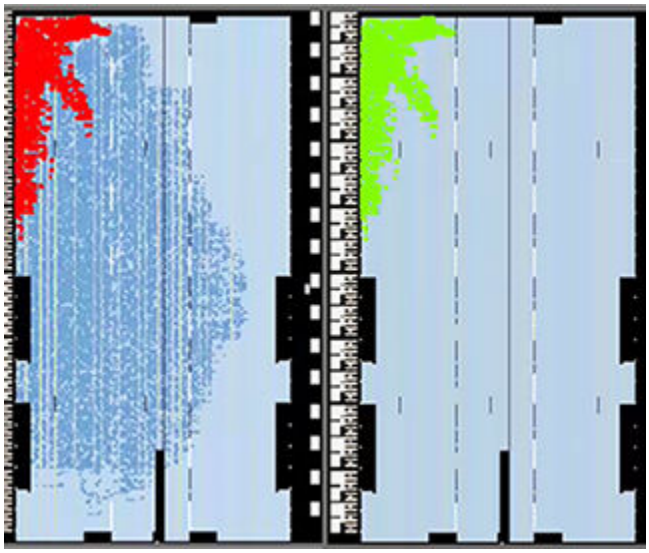
Figure 1. Core Partition Reuse Example



You can export a core block with unique characteristics that you want to retain, and then replicate that functionality or physical implementation in other projects. In the following figure, a Developer reuses the red-colored partition in the floorplan in another project shown in green in the floorplan on the right.

(1) For brevity, this document uses Developer to indicate the person or project that originates a reusable block, and uses Consumer to indicate the person or project that consumes a reusable block.

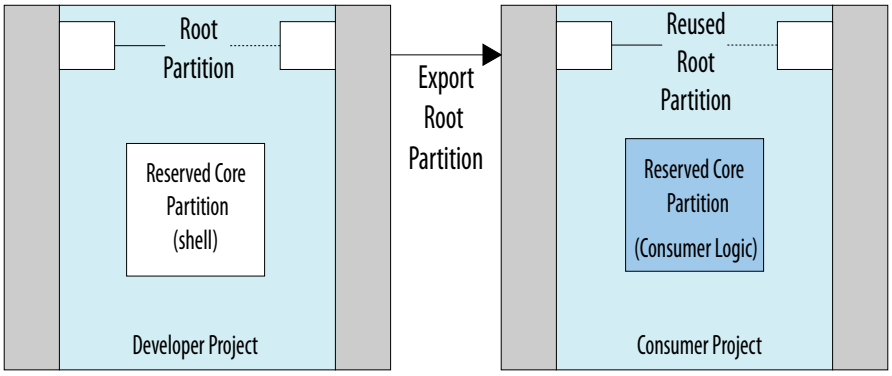
Figure 2. IP Replication and Physical Implementation



Root Partition Reuse Example

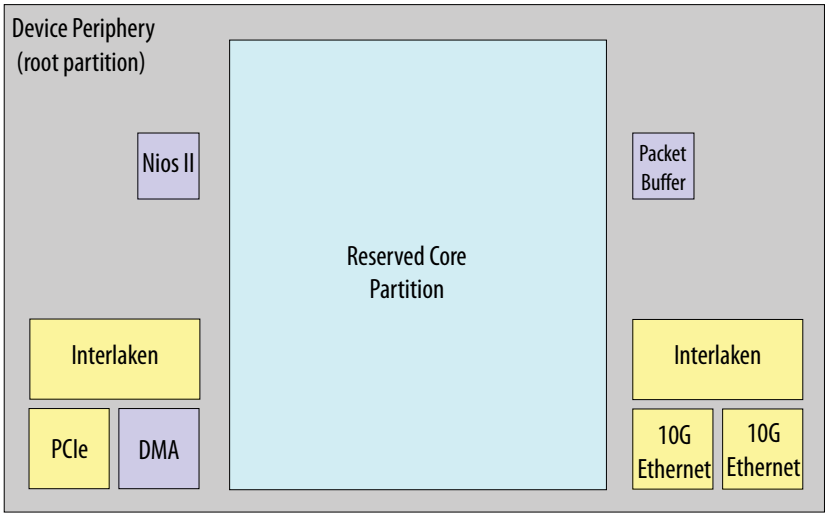
In a typical root partition reuse example, a Developer defines a root partition that includes periphery and core resources that are appropriate for reuse in other projects. An example of this scenario is reuse of the periphery for a development kit that can be reused by multiple Developers and projects.

Figure 3. Root Partition Reuse Example



In root partition reuse, each project must target the same Intel FPGA device, must have the same interfaces, and use the same version of the Intel Quartus Prime Pro Edition software. The following example shows reuse of an optimized root partition that contains various periphery interfaces. Only the reserved core partition that contains custom logic changes between Consumer projects.

Figure 4. Root Partition Reuse Example



You can reuse the root partition with multiple other boards. The root partition Developer creates a design that meets expected design requirements with all the required resources, while also reserving a region (the reserved core) for Consumer development. The Developer then exports the root partition as a `.qdb` file and passes the `.qdb` to the Consumers of the partition.

The Consumer reuses the root partition, and adds their own RTL for the reserved core. This flow allows for development on several different boards with a common root partition. Reusing the root partition saves the Consumer development time, because the root partition is pre-optimized by the Developer.

1.2.2. Incremental Block-Based Compilation Overview

You can use incremental block-based compilation to reduce overall compile time through design abstraction with empty design partitions.

You can specify a design partition as *Empty* to represent parts of your design that are incomplete or missing. Setting a partition to **Empty** can reduce the total compilation time if the Compiler does not process design logic associated with the empty partition.

Empty partitions allow you to:

- Set aside incomplete portions of the design, mark them as **Empty**, and complete the design incrementally.
- Designate complete portions of the design as **Empty** to focus all subsequent Compiler efforts on uncompleted portions of the design

1.3. Design Methodologies Overview

Block-based design flows support top-down, bottom-up, and team-based design methodologies. The following sections describe these methods.

1.3.1. Top-Down Design Methodology Overview

In a top-down design methodology, you plan the design at the top level, and then split the design into lower-level design blocks. Different developers or IP providers can create and verify HDL code for the lower-level design blocks separately, but one team lead manages the implementation project for the entire design.

In the top-down methodology, you can use core block reuse to preserve the core logic by exporting the `.qdb` file. Another developer working on the same project can then reuse the core logic `.qdb` file.

You can similarly preserve the root partition by exporting the root `.qdb` file, using the root partition reuse flow, and then reusing that root partition in the same project.

1.3.2. Bottom-Up Design Methodology Overview

In a bottom-up design methodology, you create lower-level design blocks independently of one another, and then integrate the blocks at the top-level.

To implement a bottom-up design, individual developers or IP providers can complete the placement and routing optimization of their design in separate projects, and then reuse lower-level blocks in the top-level project. This methodology can be useful for team-based design flows with developers in other locations, or when third-parties create design blocks.

However, when developing design blocks independently in a bottom-up design flow, individual developers may not have all the information about the overall design, or understand how their block connects with other blocks. The absence of this information can lead to problems during system integration, such as difficulties with timing closure, or resource conflicts. To reduce such difficulties, plan the design at the top level, whether optimizing within a single project, or optimizing blocks independently in separate projects, for subsequent top-level integration.

Teams that use a bottom-up design method can optimize placement and routing of design partitions independently. However, the following drawbacks can occur when optimizing the design partitions in separate projects:

- Achieving timing closure for the full design may be more difficult if you compile partitions independently without information about other partitions in the design. Avoiding this problem requires careful timing budgeting and observance of design rules, such as always registering the ports at the module boundaries.
- The design requires resource planning and allocation to avoid resource conflicts and overuse. Floorplanning with Logic Lock regions can help you avoid resource conflicts while developing each part independently in a separate Intel Quartus Prime project.
- Maintaining consistency of assignments and timing constraints is more difficult if you use separate Intel Quartus Prime projects. The team lead must ensure that the assignments and constraints of the top-level design, and those developers define in the separate projects and reuse at the top-level, are consistent.

Partitions that you develop independently all must share a common set of resources. To minimize issues that can arise when sharing a common set of resources between different partitions, create the partitions within in a single project, or in copies of the top-level project, with full design-level constraints, to ensure that resources do not overlap. Correct use of partitions and Logic Lock regions can help to minimize issues that can arise when integrating into the top-level design.

If a developer has no information about the top-level design, the team lead must at least provide a specific Intel FPGA device part number, along with any required physical timing constraints. The developer can then create and export the partition from a separate project. When a developer lacks information, the developer should overconstrain or create additional timing margin on the critical paths. The technique helps to reduce the chance of timing problems when integrating the partitions with other blocks.

You can use the bottom-up design methodology in conjunction with the core partition reuse flow to independently develop and export a core partition `.qdb` for reuse by a the team lead.

Related Information

Bottom-Up Design Considerations on page 28

1.3.3. Team-Based Design Methodology Overview

In a team-based design methodology, a team lead sets up the top-level project and constraints (including the top-level clock, I/O, and inter-partition constraints), and determines which portions of the design that other team members develop.

Team-based design combines a top-down methodology (where all developers must be aware of the top-level project structure and constraints), with elements of bottom-up flows (where developers work separately on lower-level blocks and integrate them into the top-level). In the top-down methodology, you can preserve the partitions and provides a `.qdb` file to other team members working on the same project.

The project lead must ensure that the top-level project contains all the interfaces for the design blocks that other team leaders add later. Each team member then develops their portion of the design, and may specify other constraints specific to their design partition. The team members implement the individual design blocks in the context of the top-level design, to avoid integration issues later. As the project nears completion, the team lead then integrates partitions from team members into the top-level project, accounting for any new constraints for the imported partitions.

Individual team members can optionally work on a copy of the same top-level project. The team member creates a partition for their respective design block, compiles the design, and then exports the partition. The team lead then integrates each design partition into the top-level design.

To simplify full design optimization, allow full-chip placement and routing of the partition at the top-level. Export and reuse only the synthesized snapshot, unless the top-level design requires optimized post-fit results.

Related Information

Setting-Up Team-Based Designs on page 26

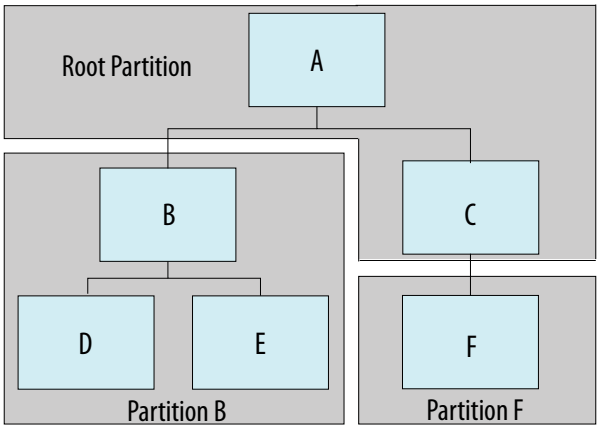
1.4. Design Partitioning

To use block-based design flows, you must first create design partitions from your design's hierarchical instances. The Compiler then treats the design partitions separately to allow the block-based functionality.

The Intel Quartus Prime software automatically creates a top-level (|) "root_partition" for each project revision. The root partition contains all the periphery resources, and may also include core resources. When you export the root partition for reuse, the exported partition excludes all logic in reserved core partitions. To export and reuse periphery elements, you export the root partition.

When you create partitions, every hierarchy within that partition becomes part of the parent partition. The partition creates a logical boundary that prevents merging or optimizing between partitions. The following *Design Partitions in Design Hierarchy* diagram illustrates design partition relationships and boundaries.

Figure 5. Design Partitions in Design Hierarchy



Note:

- Instances B and F are design partitions.
- Partition B includes sub-instances D and E.
- The root partition contains the top-level instance A and instance C, because C is unassigned to any partition.

Design partitions facilitate incremental block-based compilation and design block reuse by logically separating instances. This logical separation allows the Compiler to synthesize and optimize each partition separately from the other parts of the design. The logical separation also prevents Compiler optimizations across partition boundaries.

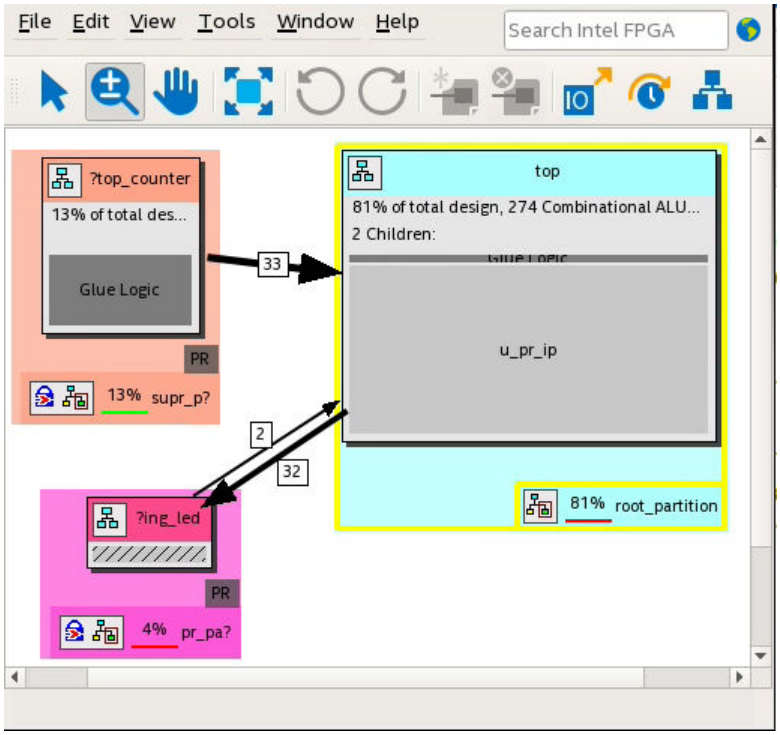
Block-based design requires that you plan and structure the source code and design hierarchy to ensure proper logic grouping for optimization. Implementing the correct logic grouping is easiest early in the design cycle.

Creating or removing a design partition changes the synthesis and subsequent physical implementation and quality of results. When planning the design hierarchy, be aware of the size and scope of each partition, and the possibility of different parts of the design changing during development. Separate logic that changes frequently from the fixed parts of the design.

Group design blocks in your design hierarchy so that highly-connected blocks have a shared level of design hierarchy for assignment to one partition. Structuring your design hierarchy appropriately reduces the required number of partition boundaries, and allows maximum optimization within the partition.

The Design Partition Planner (**Tools ➤ Design Partition Planner**) helps you to visualize and refine a design's partitioning scheme by showing timing information, relative connectivity densities, and the physical placement of partitions. You can locate partitions in other viewers, or modify or delete partitions in the Design Partition Planner.

Figure 6. Design Partition Planner



Consider creating each design entity that represents a partition instance in a separate source file. This approach helps you correlate which partitions require recompilation when you make source code changes. As you make design changes, you can designate partitions as empty or preserved (using the `.qdb` file) to instruct the Compiler which partitions to recompile from source code, as Design Abstraction on page 25 describes.

If your design has timing-critical partitions that are changing through the design flow, or partitions exported from another project, use design floorplan assignments to constrain the placement of the affected partitions. A properly partitioned and floor-planned design enables partitions to meet top-level design requirements when you integrate the partitions with the rest of your design. Poorly planned partitions or floorplan assignments negatively impact design area utilization and performance, thereby increasing the difficulty of timing closure.

The following design partition guidelines help ensure the most effective and efficient results. Block-based design flows add steps and requirements to the design process, but can provide significant benefits in design productivity.

Related Information

Step 1: Developer: Create a Design Partition on page 16

1.4.1. Planning Partitions for Periphery IP, Clocks, and PLLs

Use the following guidelines to plan partitions for periphery IP, clocks, and PLLs:

Planning Partitions for Periphery IP

- Plan the design periphery to segregate and implement periphery resources in the root partition. Ensure that IP blocks that utilize both core and periphery resources (such as transceiver and external memory interface Intel FPGA IP) are part of the root partition.
- When creating design partitions for an existing design, remove all periphery resources from any entity you want to designate as a core partition. Also, tunnel any periphery resource ports to the top level of the design. Implement the periphery resource in the root partition.
- You cannot designate instances that use periphery resources as separate partitions. In addition, you cannot split an Intel FPGA IP core into more than one partition.
- The Intel Quartus Prime software generates an error if you include periphery interface Intel FPGA IP cores in any partition other than the top-level root partition.
- You must include Intel FPGA IP cores for the Hybrid Memory Cube (HBM) or Hard Processor System (HPS) in the root partition.

Planning Partitions for Clocks and PLLs

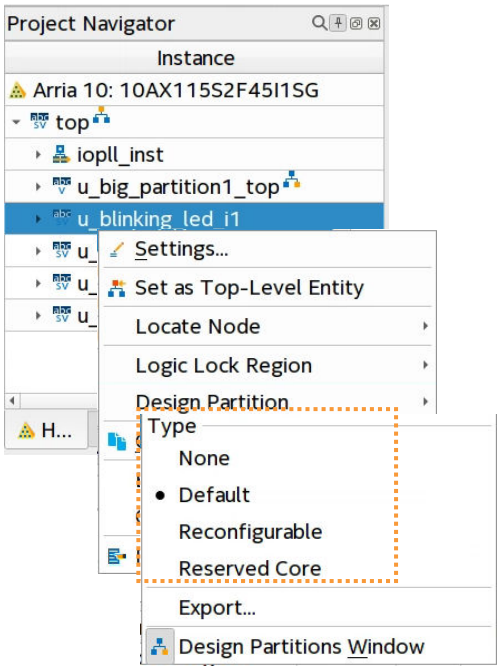
- Plan clocking structures to retain all PLLs and corresponding clocking logic in the root partition. This technique allows the Compiler to control PLLs in the root partition, if necessary.
- Consider creating a design block for all clocking logic that you instantiate in the top-level of the design. This technique ensures that the Compiler groups clocking logic together, and that the Compiler treats clocking logic as part of the root partition. Clock routing resources belong to the root partition, but the Compiler does not preserve routing resources with a partition.
- Include any signal that you want to drive globally in the root partition, rather than the core partition. Signals (such as clocks or resets) that you generate inside core partitions cannot drive to global networks without a clock buffer in the root partition.
- To support existing Intel Arria® 10 designs, the Compiler allows I/O PLLs in core partitions. However, creating a partition boundary prevents such PLLs from merging with other PLLs. The design may use more PLLs without this merging, and may have suboptimal clocking architecture.

1.4.2. Creating Design Partitions

Follow these steps to create and modify design partitions:

1. Click **Processing ➤ Start ➤ Start Analysis & Elaboration**.
2. In the Project Navigator, right-click an instance in the **Hierarchy** tab, point to **Design Partition**, and click a design partition **Type**. A design partition icon appears next to each instance you assign.

Figure 7. Creating a Design Partition from the Project Hierarchy

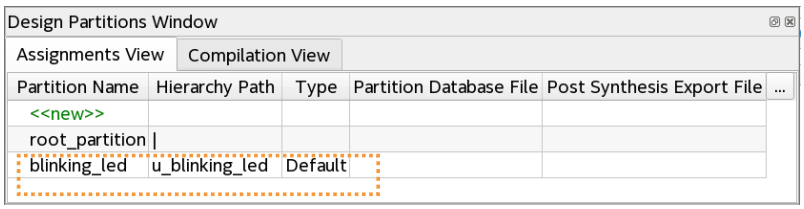


This setting corresponds to the following assignment in the `.qsf`:

```
set_instance_assignment -name PARTITION <name> \
     -to <partition hierarchical path>
```

3. To view and edit all design partitions in the project, click **Assignments ➤ Design Partitions Window**.

Figure 8. Design Partitions Window



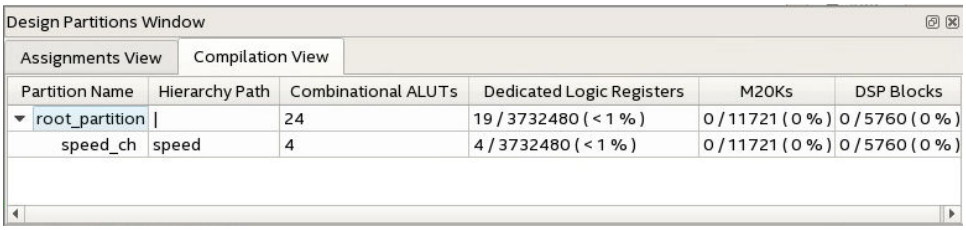
4. Specify the properties of the design partition in the Design Partitions Window. The following settings are available:

Table 2. Design Partition Settings

Option	Description
Partition Name	Specifies the partition name. Each partition name must be unique and consist of only alphanumeric characters. The Intel Quartus Prime software automatically creates a top-level (|) "root_partition" for each project revision.
Hierarchy Path	Specifies the hierarchy path of the entity instance that you assign to the partition. You specify this value in the **Create New Partition** dialog box. The root partition hierarchy path is |.
Type	Double-click to specify one of the following partition types that control how the Compiler processes and implements the partition: • **Default**—Identifies a standard partition. The Compiler processes the partition using the associated design source files. • **Reconfigurable**—Identifies a reconfigurable partition in a partial reconfiguration flow. Specify the **Reconfigurable** type to preserve synthesis results, while allowing refit of the partition in the PR flow. • **Reserved Core**—Identifies a partition in a block-based design flow that is reserved for core development by a Consumer reusing the device periphery.
Empty	Specifies an empty partition that the Compiler skips. This setting is incompatible with the **Reserved Core** and **Partition Database File** settings for the same partition.
Partition Database File	Specifies a Partition Database File (.qdb) that the Compiler uses during compilation of the partition. You export the .qdb for the stage of compilation that you want to reuse (synthesized or final). Assign the .qdb to a partition to reuse those results in another context.
Entity Re-binding	• PR Flow—specifies the entity that replaces the default persona in each implementation revision. • Root Partition Reuse Flow —specifies the entity that replaces the reserved core logic in the consumer project.
Color	Specifies the color-coding of the partition in the Chip Planner and Design Partition Planner displays.
Post Synthesis Export File	Automatically exports post-synthesis compilation results for the partition to the specified .qdb file each time Analysis & Synthesis runs. You can automatically export any design partition that does not have a preserved parent partition, including the root_partition.
Post Final Export File	Automatically exports post-final compilation results for the partition to the specified .qdb file each time the final stage of the Fitter runs. You can automatically export any design partition that does not have a preserved parent partition, including the root_partition.

Following compilation, you can view details about design partition implementation in the **Compilation View** tab of the Design Partitions Window. The synthesis and Fitter reports provide additional information about .qdb file assignments.

Figure 9. Design Partition Window Compilation View Tab



Note: You can only preserve paths inside a partition, and cannot preserve the paths crossing from one partition to another. Although you cannot merge partitions together, you can create a RTL wrapper to wrap modules that you want to group into a partition, and then assign a design partition to the RTL wrapper.

1.4.3. Design Partition Guidelines

Creating a design partition creates a logical hierarchical boundary around that instance. This partition boundary can limit the Compiler's ability to merge the partition's logic with other parts of the design. A partition boundary can also prevent optimization that reduces cell and interconnect delay, thereby reducing design performance. To minimize these effects, follow these general design partition guidelines:

- Register partition boundary ports. This practice can reduce unnecessary long delays by confining register-to-register timing paths to a single partition for optimization. This technique also minimizes the effect of the physical placement for boundary logic that the Compiler might place without knowledge of other partitions.
- Minimize the timing-critical paths passing in or out of design partitions. For timing critical-paths that cross partition boundaries, rework the partition boundaries to avoid these paths. Isolate timing-critical logic inside a single partition, so the Compiler can effectively optimize each partition independently.
- Avoid creating a large number of small partitions throughout the design. Excessive partitioning can impact performance by preventing design optimizations.
- Avoid grouping unrelated logic into a large partition. If you are working to optimize an independent block of your design, assigning that block as a small partition provides you more flexibility during optimization.

1.5. Design Block Reuse Flows

Design block reuse allows you to preserve a design partition as an exported `.qdb` file, and reuse this partition in another project. Reuse of core or root partitions involves partitioning and constraining the block prior to compilation, and then exporting the block for reuse in another project. Effective design block reuse requires planning to ensure that the source code and design hierarchy support the physical partitioning of device resources that these flows require.

- **Core partition reuse**—allows reuse of synthesized or final snapshots of a core partition. A core partition can include only core resources (LUTs, registers, M20K memory blocks, and DSPs).
- **Root partition reuse**—allows reuse of a synthesized or final snapshot of a root partition. A root partition includes periphery resources (including I/O, HSSIO, PCIe, PLLs), as well as any associated core resources, while leaving a core partition open for subsequent development.

At a high level, the core and root partition reuse flows are similar. Both flows preserve and reuse a design partition as a `.qdb` file. The Developer defines, compiles, and preserves the block in the Developer project, and the Consumer reuses the block in one or more Consumer projects.

The following sections describe the core and root partition reuse flows in detail.

Related Information

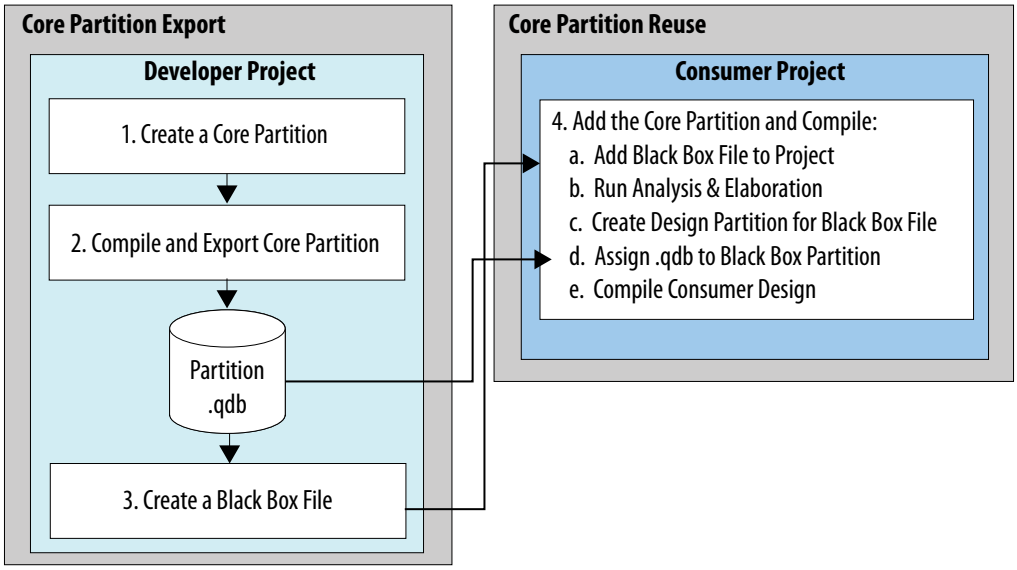
- Design Block Reuse Overview on page 4
- AN 839: Design Block Reuse Tutorial for Intel Arria 10 FPGA Development Board

1.5.1. Reusing Core Partitions

Reusing core partitions involves exporting the core partition from the Developer project as a `.qdb`, and then reusing the `.qdb` in a Consumer project.

The Consumer assigns the `.qdb` to an instance in the Consumer project. In the Consumer project, the Compiler runs stages not already exported with the partition.

Figure 10. Core Partition Reuse Flow



The following steps describe the core partition reuse flow in detail.

1.5.1.1. Step 1: Developer: Create a Design Partition

Define design partitions to create logical boundaries in the design hierarchy. Confine each core instance for export within a design partition. You can define partition instances from the Project Navigator or in the Design Partitions Window.

To define a core design partition:

1. Review the project to determine design elements suitable for reuse, and the appropriate snapshot for export.
2. Refer to Creating Design Partitions on page 13 to define a core partition. Select **Default** for the partition **Type**.

Related Information

Intel Quartus Prime Pro Edition User Guide: Partial Reconfiguration

1.5.1.2. Step 2: Developer: Compile and Export the Core Partition

This step describes generating and exporting a final snapshot of the core partition. You can manually export the core partition as a `.qdb` after compilation, or you can specify settings to automate export each time you compile. You can then reuse the core partition in the same project or in another project, starting the partition's compilation at the stage following the snapshot.

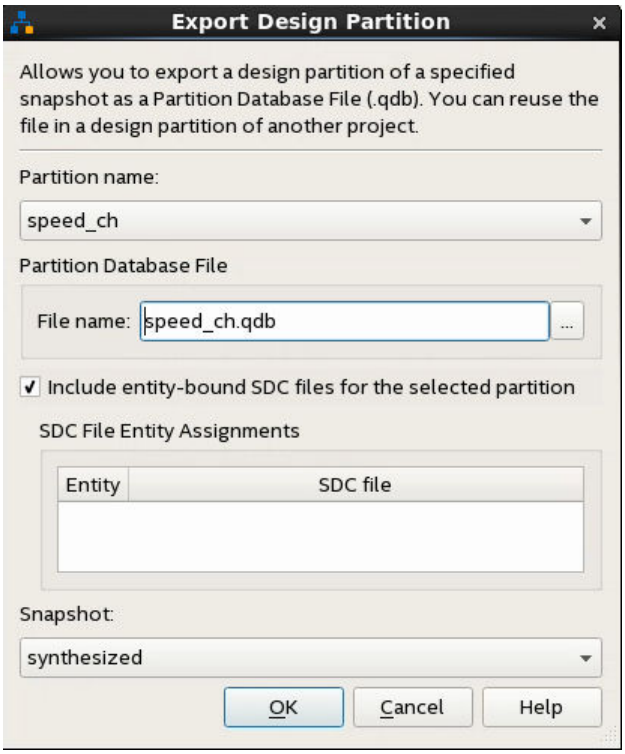
Manual Partition Export

To compile and manually export a core partition:

1. To run all compilation stages through Fitter (Finalize) and generate the final snapshot, click **Processing ➤ Start ➤ Start Fitter**.
2. To export the core partition, click **Project ➤ Export Design Partition**. Select the **Design Partition** name and the compilation **Snapshot** for export.
3. To include any entity-bound `.sdc` files in the exported `.qdb`, turn on **Include entity-bound SDC files for the selected partition**. By default, all Intel FPGA IP targeting Intel Stratix® 10 devices use entity-bound `.sdc` files.

   Note: Intel FPGA IP targeting Intel Arria 10 devices do not use entity-bound `.sdc` files by default. To use this option for Intel Arria 10 devices, you must first bind the `.sdc` file to the entity in the `.qsf`. Refer to "Using Entity-bound SDC Files," in *Intel Quartus Prime Pro Edition User Guide: Timing Analyzer*.
4. Confirm the **File name** for the **Partition Database File**, and then click **OK**.

Figure 11. Export Design Partition



The following command corresponds to partition export in the GUI:

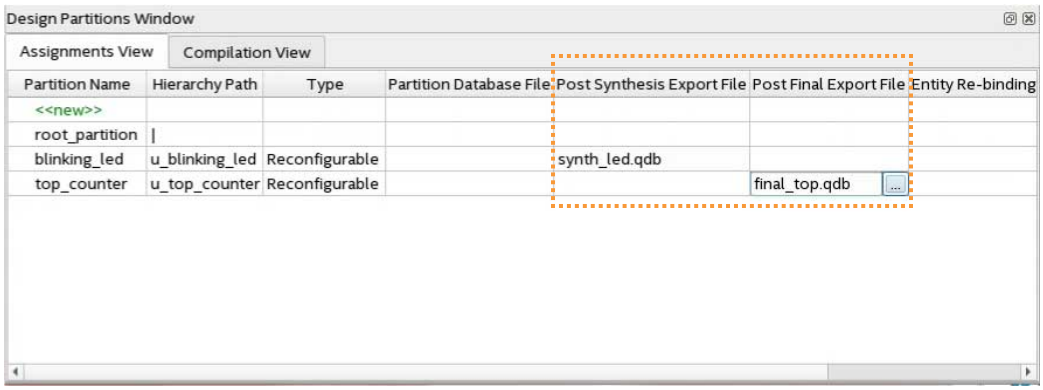
```
quartus_cdb <project name> -c <revision name> \
     --export_partition "<name>" --snapshot synthesized \
     --file <name>.qdb –-include_sdc_entity_in_partition
```

Automated Design Partition Export

Follow these steps in the Design Partitions Window to automatically export one or more design partitions following each compilation:

1. To automatically export a partition with synthesis results after each time you run synthesis, specify the a `.qdb` export path and file name for the **Post Synthesis Export File** option for that partition. If you specify only a file name without path, the file exports to the project directory after compilation.
2. To automatically export a partition with final snapshot results each time you run the Fitter, specify a `.qdb` file name for the **Post Final Export File** option for that partition.

Figure 12. Specifying Export File in Design Partitions Window



`.qsf` assignment syntax:

```
set_instance_assignment -name EXPORT_PARTITION_SNAPSHOT_SYNTHESIZED \
     <qdb file name> -to <hierarchy path> -entity <entity name>
```

Related Information

"Using Entity-bound SDC Files," Intel Quartus Prime Pro Edition User Guide: Timing Analyzer

1.5.1.3. Step 3: Developer: Create a Black Box File

Reusing a core partition `.qdb` file also requires that you add a supporting black box file to the Consumer project. A black box file is an RTL source file that only contains port and module or entity definitions, but does not contain any logic. The black box file defines the ports and port interface types for synthesis in the Consumer project. Follow these steps to create a block box port definitions file for the partition.

The Compiler analyzes and elaborates any RTL that you include in the black box file. Edits to the RTL do not affect a partition that uses a `.qdb` file.

1. Create an HDL file (`.v`, `.vhd`, `.sv`) that contains only the port definitions for the exported core partition. Include parameters or generics passed to the module or entity. For example:

```
module bus_shift #(
    parameter DEPTH=256,
    parameter WIDTH=8
  )(
```

```
    input clk,
    input enable,
    input reset,
    input [WIDTH-1:0] sr_in,
    output [WIDTH-1:0] sr_out
  );
endmodule
```

2. Provide the black box file and exported core partition `.qdb` file to the Consumer.

1.5.1.4. Step 4: Consumer: Add the Core Partition and Compile

To add the core partition, the Consumer adds the black box as a source file in the Consumer project. After design elaboration, the Consumer defines a core partition and assigns the exported `.qdb` file to an instance in the Design Partitions Window. Because the exported `.qdb` includes compiled netlist information, the Consumer project must target the same FPGA device family, and use the same Intel Quartus Prime software version, as the Developer project. The Consumer must supply a clock and any other constraints required for the interface to the core partition.

To add the core partition and compile the Consumer project:

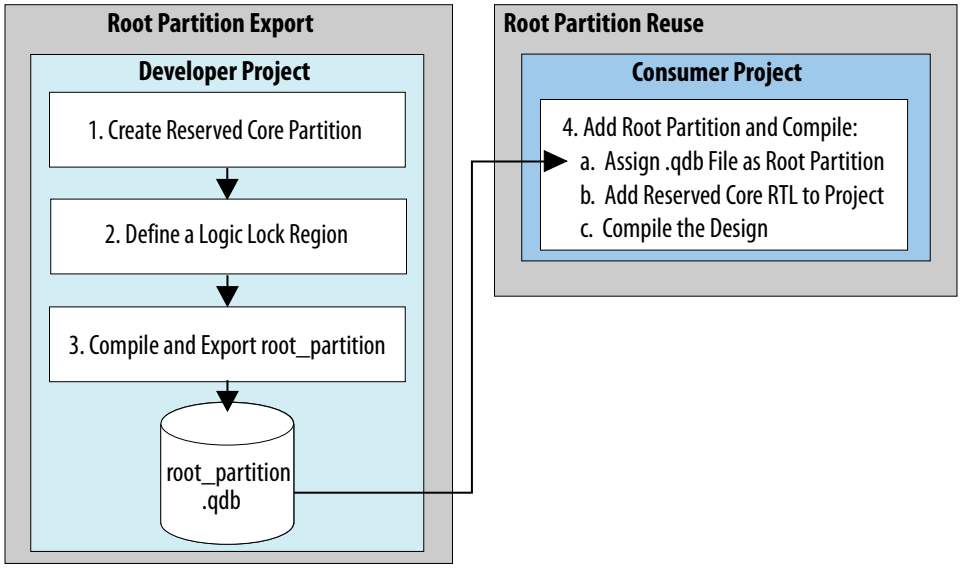
1. Create or open the Intel Quartus Prime project that you want to reuse the core partition.
2. To add one or more black box files to the consumer project, click **Project ➤ Add/Remove Files in Project** and select the black box file.
3. Follow the steps in Creating Design Partitions on page 13 to elaborate the design and define a core partition for the black box file. When defining the design partition, click the **Partition Database File** option and select the exported `.qdb` file for the core partition.
4. To run all compilation stages through Fitter (Finalize) and generate the final snapshot, click **Processing ➤ Start ➤ Start Fitter**.

1.5.2. Reusing Root Partitions

The root partition contains all the periphery resources, and may also include some core resources. To export and reuse periphery elements, you export the root partition. Reuse of root partitions allows you to design an FPGA-to-board interface and associated logic once, and then replicate that interface in other projects.

Note: When reusing the root partition across different devices within the same family, you can only reuse the Synthesized snapshot, and you must ensure that any Fitter constraints (such as Logic Lock regions) from the Developer project do not conflict with constraints in the Consumer project.

Figure 13. Root Partition Reuse Flow



1.5.2.1. Step 1: Developer: Create a Reserved Core Partition

To export and reuse the root partition, the Developer creates a reserved core partition for later core logic development in the Consumer project. The Compiler preserves post-fit results for the partition and reuses the post-fit netlist, if the netlist is available from previous compilation, and you make no partition changes requiring re-synthesis. Otherwise, the Compiler reuses the post-synthesis netlist if available, or resynthesizes the partition from source files.

To create a reserved core partition:

1. Adapt the steps in Step 1: Developer: Create a Design Partition on page 16 to create a reserved core partition.
2. When defining the design partition, select **Reserved Core** for the partition **Type**. Ensure that all other partition options are set to the default values.

1.5.2.2. Step 2: Developer: Define a Logic Lock Region

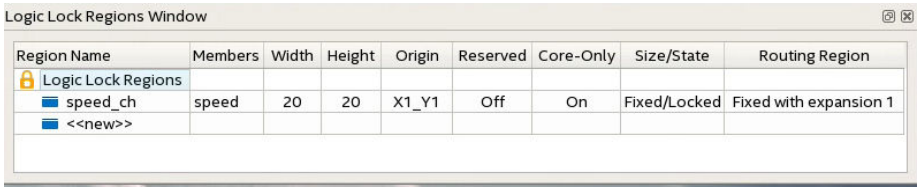
To reserve core resources in a Consumer project for the reserved core partition, the Developer defines a fixed size and location, core-only, reserved Logic Lock region with a defined routing region. The Consumer uses this same region in their project for core development. This region can contain only core logic. Ensure that the reserved placement region is large enough to contain all core logic that the Consumer plans to develop. For projects with multiple core partitions, constrain each partition in a non-overlapping Logic Lock routing region.

Note: When reusing the root partition across different devices within the same family, you can only reuse the Synthesized snapshot, and you must ensure that any Fitter constraints (such as Logic Lock regions) from the Developer project do not conflict with constraints in the Consumer project.

Follow these steps to define a Logic Lock region for core development in the Developer project:

1. Right-click the design instance in the **Project Navigator** and click **Logic Lock Region ➤ Create New Logic Lock Region**. The region appears in the Logic Lock Regions Window. You can also verify the region in the Chip Planner (**Locate Node ➤ Locate in Chip Planner**).
2. Specify the placement region co-ordinates in the **Origin** column.
3. Enable the **Reserved** and **Core-Only** options.
4. For **Size/State**, select **Fixed/Locked**.
5. Click the **Routing Region** cell. The **Logic Lock Routing Region Settings** dialog box appears.

Figure 14. Logic Lock Regions Window



6. Specify **Fixed with expansion** with **Expansion Length** of **1** for the **Routing Type**. For this flow you can select any value other than **Unconstrained**
7. Click **OK**.
8. Click **File ➤ Save Project**.

1.5.2.3. Step 3: Developer: Compile and Export the Root Partition

After compilation, the Developer exports the root partition at the synthesized or final stage. The Developer supplies any Synopsys* Design Constraints (`.sdc`) file for the partition. The Developer uses the `.sdc` files to drive placement and routing. The Consumer uses `.sdc` files for evaluation of partitions that reuse `.qdb` files, and to drive placement in the Fitter for non-reused or non-preserved partitions.

1. To run all compilation stages through Fitter (Finalize), click **Processing ➤ Start ➤ Start Fitter**.
2. To export the root partition to a `.qdb` file, click **Project ➤ Export Design Partition**. Select the **root_partition** and the **synthesized** or **final** snapshot.
3. To include any entity-bound `.sdc` files in the exported `.qdb`, turn on **Include entity-bound SDC files for the selected partition**. By default, all Intel FPGA IP targeting Intel Stratix 10 devices use entity-bound `.sdc` files.

   The following command corresponds to the root partition export in the GUI:

   ```
   quartus_cdb <project name> -c <revision name> \
        --export_partition "root_partition" --snapshot final \
        --file root_partition.qdb --include_sdc_entity_in_partition
   ```

4. The Developer provides the exported `.qdb` file and `.sdc` files for the reserved core to the Consumer.

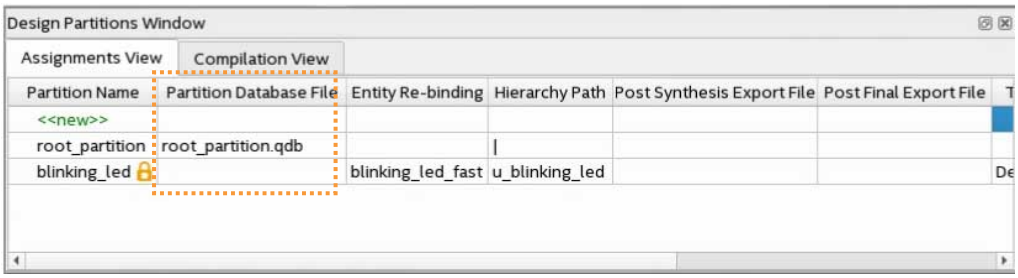
1.5.2.4. Step 4: Consumer: Add the Root Partition and Compile

To reuse the root partition in another project, the Consumer assigns the exported root partition `.qdb` in the Consumer project settings. The root partition `.qdb` includes all Logic Lock region and partition information for the reserved core from the Developer project. There is no need to recreate these constraints in the Consumer project. After assigning the `.qdb`, the Consumer project includes all additional information from the Developer project compilation snapshot. The Consumer then adds RTL for the reserved core partition.

Follow these steps to reuse the root partition in a Consumer project:

1. The Consumer obtains the exported root partition `.qdb` file from the Developer.
2. Open the project that you want to reuse the exported root partition.
3. In the Design Partitions Window, specify a `.qdb` in **Partition Database File** to replace the root_partition logic.

Figure 15. Partition Database File Option in Design Partitions Window



4. The Consumer adds RTL and any `.sdc` constraints for the reserved core partition.
5. To enable the **Fast Preserve** option that simplifies the logic of the preserved partition to only interface logic[2] during compilation, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Incremental Compile ➤ Fast Preserve**.
6. To run all compilation stages, click **Processing ➤ Start Compilation**. The Compiler implements the reused root partition and constraints.

   Note: To use the Entity Re-binding option, you add the .qdb to the project by specifying a .qdb for the **Partition Database File** option in the Design Partitions Window. Refer to Reserved Core Entity Re-Binding on page 22 for more information.

1.5.3. Reserved Core Entity Re-Binding

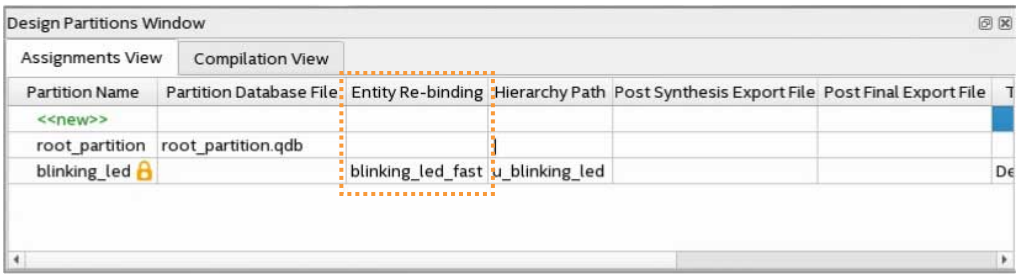
Entity re-binding allows the Consumer in a root partition reuse flow to use an entity name that is different from the Developer's reserved core partition name in the `root_partition.qdb`.

Entity Re-binding Example

The following example illustrates application of **Entity Re-binding**. You specify a value for the **Entity Re-binding** option in the Design Partitions Window to identify the entity bound to a reserved core partition.

[2] Interface logic is logic at the partition boundary that interfaces with the rest of the design.

Figure 16. Entity Rebinding Option in Design Partitions Window



In a root partition reuse example, the Developer's project includes the shell with entity name `blinking_led`, and the `u_blinking_led` instance. The Developer exports the `root_partition.qdb` that includes the root partition, and a reserved core region defined by a Logic Lock placement constraint. The reserved region is associated with the `u_blinking_led` instance.

The Consumer reuses the `root_partition.qdb` in their project. However, the entity that replaces the reserved core has a different name (`blinking_led_fast`) than the reserved core name (`u_blinking_led`) in the Developer project.

If the Consumer simply adds the `u_blinking_led` entity to the project without entity re-binding, an error occurs.

Rather, the Consumer can re-bind the new entity name to the reserved core partition name by setting the **Entity Re-binding** option to `blinking_led_fast`.

1.5.4. Viewing Quartus Database File Information

Although you cannot directly read a `.qdb` file, you can view helpful attributes about the file to quickly identify its contents and suitability for use.

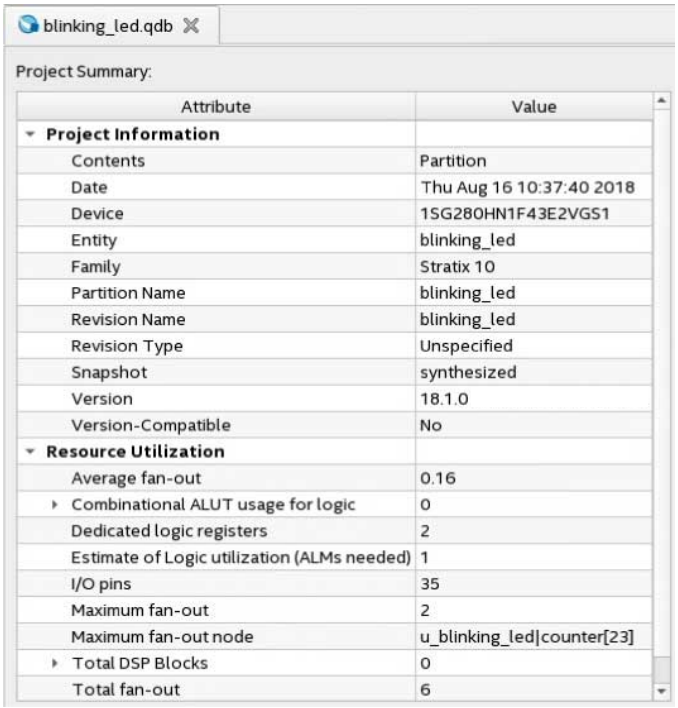
The Intel Quartus Prime software automatically stores metadata about the project of origin when you export a Quartus Database File (`.qdb`). You can then use the Quartus Database File Viewer to display the attributes of any of these `.qdb` files.
Follow these steps to view the attributes of a `.qdb` file:

1. In the Intel Quartus Prime software, click **File ➤ Open**, select **Design Files** for **Files of Type**, and select a `.qdb` file.
2. Click **Open**. The Quartus Database File Viewer displays project and resource utilization attributes of the `.qdb`.

   Alternatively, run the following command-line equivalent:

```
quartus_cdb --extract_metadata --file <archive_name.qdb> \
     --type quartus --dir <extraction_directory> \
     [--overwrite]
```

Figure 17. Quartus Database File Viewer



1.5.4.1. QDB File Attribute Types

The Quartus Database Viewer can display the following attributes of a `.qdb` file:

Table 3. QDB File Attributes

QDB Attribute Types	Attribute	Example
Project Information	Contents	`Partition`
	Date	`Thu Jan 23 10:56:23 2018`
	Device	`10AX016C3U19E2LG`
	Entity (if Partition)	`Counter`
	Family	`Arria 10`
	Partition Name	`root_partition`
	Revision Name	`Top`
	Revision Type	`PR_BASE`
	Snapshot	`synthesized`
	Version	`18.1.0 Pro Edition`
	Version-Compatible	`Yes`
Resource Utilization (exported for partition QDB only)	For synthesized snapshot partition lists data from the **Synthesis Resource Usage Summary** report.	`Average fan-out.16` `Dedicated logic registers:14` `Estimate of Logic utilization:1`

continued...

		I/O pins:35 Maximum fan-out:2 Maximum fan-out node:counter[23] Total DSP Blocks:0 Total fan-out:6 ...
	For the final snapshot partition, lists data from the **Fitter Partition Statistics** report.	Average fan-out:.16 Combinational ALUTs: 16 I/O Registers M20Ks ...

1.6. Incremental Block-Based Compilation Flow

The incremental block-based compilation flow allows you to perform design abstraction by emptying a partition.

1.6.1. Design Abstraction

Empty partitions are useful to account for undefined partitions developed independently or later in the design cycle. The Compiler uses an empty placeholder netlist for the partition, ties the partition output ports to ground, and removes the input ports. The Compiler removes any existing synthesis, placement, and routing information for an empty partition.

If you remove the **Empty** setting from a partition, the Compiler re-implements the partition from the source. Setting a partition to **Empty** can reduce design compilation time because the top-level design netlist does not include the logic for the empty partition. The Compiler does not run full synthesis and fitting algorithms on the empty partition logic.

Note: To avoid resource conflicts when using empty partitions, floorplan any empty partitions that you intend to subsequently replace with a `.qdb`.

Follow these steps to define an empty partition:

1. Create a design partition, as Step 1: Developer: Create a Design Partition on page 16 describes. Set the partition **Type** to **Default**. Any other setting is incompatible with empty partitions.
2. For the **Empty** option, select **Yes**. This setting corresponds to the following assignment in the `.qsf`.

```
set_instance_assignment -name EMPTY ON -to \
     <hierarchal path of partition> -entity <name>
```

1.6.1.1. Empty Partition Clock Source Preservation

Empty partitions preserve clock sources that the Intel Quartus Prime software recognizes.

The Intel Quartus Prime software recognizes and preserves the following as clock sources for a partition:

- Signals from a PLL.
- Feeds from internal clock inputs on flip-flops, memories, HSSIO, I/O registers, or PLLs outside the partition that you empty.

The Intel Quartus Prime software does not recognize the following as clock sources for a partition:

- Nets with sources external to the FPGA that do not feed a clock input inside the FPGA.
- Nets that connect only to combinatorial logic.
- Nets that connect only to an output pin.
- Nets that feed only logic within an empty partition.

1.7. Setting-Up Team-Based Designs

Use the following procedures to setup a project for a team-based design methodology.

1.7.1. Creating a Top-Level Project for a Team-Based Design

In team-based designs that reuse design blocks, all team members ideally work within the same top-level project framework. Using copies of the same project among team members ensures that everyone has the same settings and constraints that their partition requires.

This method helps the team to integrate the partitions into the top-level design. If some Developers do not have access to the top-level project framework, the team lead must provide information about the project and constraints to those Developers.

The following steps describe preparing a top-level project that enables other Developers to provide optimized lower-level design partitions. The top-level project specifies the top-level entity, and then instantiates other design entities that other Developers optimize in a separate Intel Quartus Prime project.

1. Set up the top-level project and add source files. You can represent incomplete sections of the design by adding black box files, as Step 3: Developer: Create a Black Box File on page 18 describes.
2. Define design partitions for any instance that you want to maintain as a separate Intel Quartus Prime project, as Creating Design Partitions on page 13 describes.
3. Define an empty partition for each design partition with unknown or incomplete definition.
4. Create a Logic Lock region constraint for each design block that you plan to integrate as a separate Intel Quartus Prime project. This physical partitioning of the device allows multiple team members to design independently without placement conflicts, as Step 2: Developer: Define a Logic Lock Region on page 20 describes.
5. To run full compilation, click **Processing ➤ Start Compilation**.
6. Use one of the following methods to provide the top-level project information to design Developers:

- If Developers have access to the top-level project framework, the team lead includes all settings and constraints. This framework may include clocks, PLLs, and other periphery interface logic that the Developer requires to develop their partition. If Developers are part of the same design environment, they can check out a copy of the project files they require from the same source control system. This is the best method for sharing a set of project files. Otherwise, the team lead provides a copy of the top-level project (the design and corresponding `.qsf` assignments), so that each Developer creates their partition within the same project framework.
- If Developers do not have access to the top-level project framework, the team lead provides a Tcl script or other specifications to create a separate Intel Quartus Prime project that matches the top-level. The team lead also adds logic around the design block for export, so that the partition is consistent with the key characteristics of the top-level design environment. For example, the team lead can include a top-level PLL in the project, outside of the partition for export, so that Developers can optimize the design with information about the clocks and PLL parameters. This technique provides more accurate timing requirements. Export the partition for the top-level design, without exporting any auxiliary components that you instantiate outside the partition you are exporting.

1.7.1.1. Prepare a Design Partition for Project Integration

Follow these steps to prepare a lower-level design partition for integration with the top-level project:

1. Obtain a copy of the top-level project, or create a new project with the same assignments and constraints as the top-level project. Ensure that your partition uses only the resources that the team lead allocates.
2. For each design partition that is incomplete in the top-level project, set the **Empty** option to **Yes** in the Design Partitions Window. This setting creates an empty partition for later development. For the Compiler to elaborate this partition, you must provide at least the port definitions and any parameters or generics passed to the RTL.
3. When the lower-level design partition is complete, follow the procedure in Step 2: Developer: Compile and Export the Core Partition on page 16. The project lead can now reuse the partition in the top-level project.

1.8. Bottom-Up Design Considerations

Consider the following when using bottom-up design methodology:

Table 4. Bottom-Up Design Recommendations and Limitations

Recommendation/ Limitation	Description
Recommendation 1	Define Logic Lock constraints that are **Reserved**, **Core-Only**, **Fixed/Locked**, with a specified **Routing Region**. While exporting partitions from a different project with a different top-level, generate the partitions with non-overlapping Logic Lock routing regions by setting the routing region to **Fixed with expansion** of 0.
Limitation 1	If you compile two partitions, in two different projects, with `top_level_1.sv` and `top_level_2.sv`, and reuse the partitions in a third project with `top_level_3.sv`, the Compiler cannot support two partitions with overlapping row clock regions. Apply Logic Lock region constraints in the Developer project to avoid two partitions occupying the same row clock region in the Consumer project. For example: 1. From the Consumer project, determine the approximate placement of the two partitions. Choose the Logic Lock constraints for the two partitions such that there is no overlap of the row clock region. 2. In the Developer project with `top_level_1.sv`, apply Logic Lock region constraints that the Consumer identifies for the first partition, followed by compilation and export of the partition at final snapshot. 3. In the Developer project with `top_level_2.sv`, apply Logic Lock region constraints that the Consumer identifies for the second partition, followed by compilation and export of the partition at final snapshot. 4. When reusing the exported partitions in the consumer project with `top_level_3.sv`, the partitions maintain the placement defined in the Developer projects using non-overlapping Logic Lock constraints.
Limitation 2	System-level design errors may not become apparent until late in the design cycle, which can require additional design iterations to resolve.

1.10. Block-Based Design Flows Revision History

Document Version	Intel Quartus Prime Version	Changes
2023.11.07	23.3	• Added Top FAQs navigation to the document cover. • Removed references to design block preservation as new DNI infrastructure does not support the "preserve" assignment.
2019.12.16	19.4.0	• Updated for cross-device snapshot reuse support and limits throughout.
2019.11.11	19.2.0	• Described Fast Preserve option in "Block-Based Design Terminology" and "Step 4: Add the Root Partition and Compile."
2019.07.15	19.2.0	• Changed default file export location from output_files to project directory. • Updated description of partition type GUI. • Updated Support for "Combined Incremental Block-Based Compilation and Design Block Reuse" table for latest supported combinations. • Added note about merging partitions to "Creating Design Partitions."
2018.10.01	18.1.0	• Removed reference to Placed snapshot from "Step 3: Compile and Export the Root Partition." Only Synthesized and Final snapshots are supported for design block reuse.
2018.09.24	18.1.0	• Reorganized order of topics in chapter. • Added the following new topics: — Viewing Quartus Database File Information — Reserved Core Entity Re-Binding — Incremental Block-Based Compilation Examples — Design Methodologies — Top-Down Design Methodology Overview — Bottom-Up Design Methodology Overview — Bottom-Up Design Recommendations and Limitations — Team-Based Design Methodology Overview — Incremental Timing Closure — Incremental Timing Closure Recommendations and Limitations — Design Abstraction • Replaced references to "periphery reuse core" with "reserved core" to reflect latest GUI. • Added description of | as root partition hierarchy path in Design Partitions Window. • Replaced details in "Debugging Block-Based Designs with the Signal Tap Logic Analyzer" section with link to *AN 847: Signal Tap Tutorial with Design Block Reuse for Intel Arria 10 FPGA Development Board*. • Minor wording and graphic updates throughout. • Removed references to unsupported Planned snapshot.
2018.05.07	18.0.0	• First release of chapter as part of stand-alone *Block-Based Design User Guide*. • Added footnote and links to known issues. • Updated all design flow steps to match current GUI. • Updated description of Include entity-bound SDC files option. • Updated statement defining parent to child partition attribute inheritance. • Added *Design Partition Settings* topic. • Added *Block-Based Design Terminology* topic. • Added *Preservation and Reuse with Compiler Snapshots* topic. • Added *Empty Partition Clock Source Preservation* topic.

continued...

Document Version	Intel Quartus Prime Version	Changes
		• Added *Design Partitions Properties* table. • Added *Combining Incremental Block-Based Compilation and Design Block Reuse* topic. • Updated *Debugging Block-Based Designs* topic and linked to new Application Note.
2017.11.06	17.1.0	• Reorganization of introduction and Incremental Block-Based Compilation. • Added *Design Partitioning* section. • Added *Debugging Block-Based Designs* section. • Added *Use Empty Partitions to Reduce Compilation Time* topic. • Removed requirement to add `.psmf`, `.msf`, and `.sof` to Consumer project. • Added Intel Stratix 10 support, including information about bundling of `.sdc` with exported partitions for Intel Stratix 10 designs. • Documented changes to Design Partitions window, Export Design Partition dialog box, and Logic Lock Regions window. • Added reference to new Design Partition Planner. • Updated references to corresponding `.qsf` assignments. • Changed references from periphery reuse to root partition reuse. • Rebranded for latest Intel standards.
2017.05.08	17.0.0	• First public release.

  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Intel Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Intel Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Intel Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Intel Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Intel Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Intel Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Intel Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Intel Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Intel Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Intel Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

Quartus® Prime Pro Edition User Guide

Partial Reconfiguration

Updated for Quartus® Prime Design Suite: **24.1**

This document is part of a collection - Quartus® Prime Pro Edition User Guides - Combined PDF link

Answers to Top FAQs:

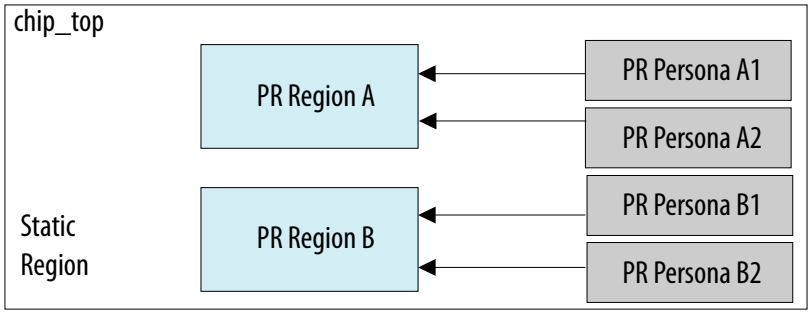
Contents

1. Creating a Partial Reconfiguration Design

Partial reconfiguration (PR) allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. You can define multiple personas for a particular region in your design, without impacting operation in areas outside this region. This methodology is effective in systems with multiple functions that time-share the same FPGA device resources. PR enables the implementation of more complex FPGA systems.

The Quartus® Prime Pro Edition software supports the PR feature for the Stratix® 10, Agilex™ 7, Agilex 5, Arria® 10, and Cyclone® 10 GX device families.

Figure 1. Partial Reconfiguration Design



PR provides the following advancements over a flat design:

- Allows run-time design reconfiguration
- Increases scalability of the design through time-multiplexing
- Lowers cost and power consumption through efficient use of board space
- Supports dynamic time-multiplexing functions in the design
- Improves initial programming time through smaller bitstreams
- Reduces system down-time through line upgrades
- Enables easy system update by allowing remote hardware change
- A simplified compilation flow for partial reconfiguration

Hierarchical Partial Reconfiguration

Quartus Prime Pro Edition software also supports hierarchical partial reconfiguration (HPR), with multiple parent and child design partitions, or multiple levels of partitions in a design. In HPR designs, a static region instantiates a parent PR region, and a parent PR region instantiates a child PR region. The same PR region reprogramming is possible for the child and parent partitions. Refer to Hierarchical Partial Reconfiguration on page 49.

Static Update Partial Reconfiguration

Static update partial reconfiguration (SUPR) allows you to define and modify a specialized static region, without requiring recompilation of all personas. This technique is useful for a portion of a design that you may possibly want to change for risk mitigation, but that never requires runtime reconfiguration. In PR without a SUPR partition, you must recompile all personas for any change to the static region. Refer to the Partial Reconfiguration Tutorials for detailed SUPR instructions.

Partial Reconfiguration Design Simulation

The Quartus Prime Pro Edition software supports simulation of PR persona transitions through the use of simulation multiplexers. You use the simulation multiplexers to change which persona drives logic inside the PR region during simulation. This simulation allows you to observe the resulting change and the intermediate effect in a reconfigurable partition. Refer to Partial Reconfiguration Design Simulation on page 52 for details.

1.1. What's New In This Version

- Referenced support for Agilex 5 devices and applied initial Altera rebranding.
- For change details, refer to the Creating a Partial Reconfiguration Design Revision History on page 70 and Partial Reconfiguration Solutions IP User Guide Revision History on page 146.

1.2. Partial Reconfiguration Terminology

This document refers to the following terms to explain partial reconfiguration:

Table 1. Partial Reconfiguration Terminology

Term	Description
Floorplan	The layout of physical resources on the device. Creating a design floorplan, or floorplanning, is the process of mapping the logical design hierarchy to physical regions in the device. PR requires floorplanning.
Hierarchical Partial Reconfiguration	Partial reconfiguration that includes multiple parent and child design partitions, or nesting of partitions in the same design.
PR control block	A dedicated block in Arria 10 and Cyclone 10 GX FPGAs. The PR control block processes the PR requests, handshake protocols, and verifies the cyclic redundancy check (CRC).
PR host	The system for coordinating PR. The PR host communicates with the PR control block (Arria 10 and Cyclone 10 GX designs) or Secure Device Manager (Stratix 10, Agilex 7, and Agilex 5 designs). Implement the PR host within the FPGA (internal PR host) or in a chip or microprocessor.
PR partition	Design partition that you designate as **Reconfigurable**. A PR project can contain one or more PR partitions.
PR Solutions Intel® FPGA IP	Suite of Intel FPGA IP that simplify implementation of PR handshaking and freeze logic, as Partial Reconfiguration Solutions IP User Guide on page 74 describes.

continued...

Term	Description
PR region	A physical portion of an FPGA device that you designate for partial reconfiguration. You define a PR region in the base configuration design. A device can contain more than one PR region. A PR region must be core-only, containing only core resources like LABs, RAM blocks, and DSP blocks. The PR region bitstream configures this region.
PR persona	A specific PR partition implementation in a PR region. A PR region can contain multiple personas. Static regions contain only one persona.
Revision	A collection of settings and constraints for one version of your project. An Quartus Prime Settings File (`.qsf`) preserves each revision of your project. Your Quartus Prime project can contain several revisions. Revisions allow you to organize several versions of your design within a single project.
Secure Device Manager (SDM)	A triple-redundant processor-based block in Agilex 7, Agilex 5, and Stratix 10 devices that performs authentication, decryption, and decompression on the configuration data the block receives, before sending the data over to the configurable nodes through the configuration network.
Snapshot	The output of a Compiler stage. You can export the synthesis or final compilation results snapshot.
Static region	All areas not occupied by PR regions in your project. You associate the static region with the top-level partition of the design. The static region contains both the core and periphery locations of the device. The static region bitstream configures this region.
Static update partial reconfiguration	A static region that you can change, without requiring the recompilation of all personas. This technique is useful for a portion of a design that you may *possibly* want to change for risk mitigation, but that never requires runtime reconfiguration.

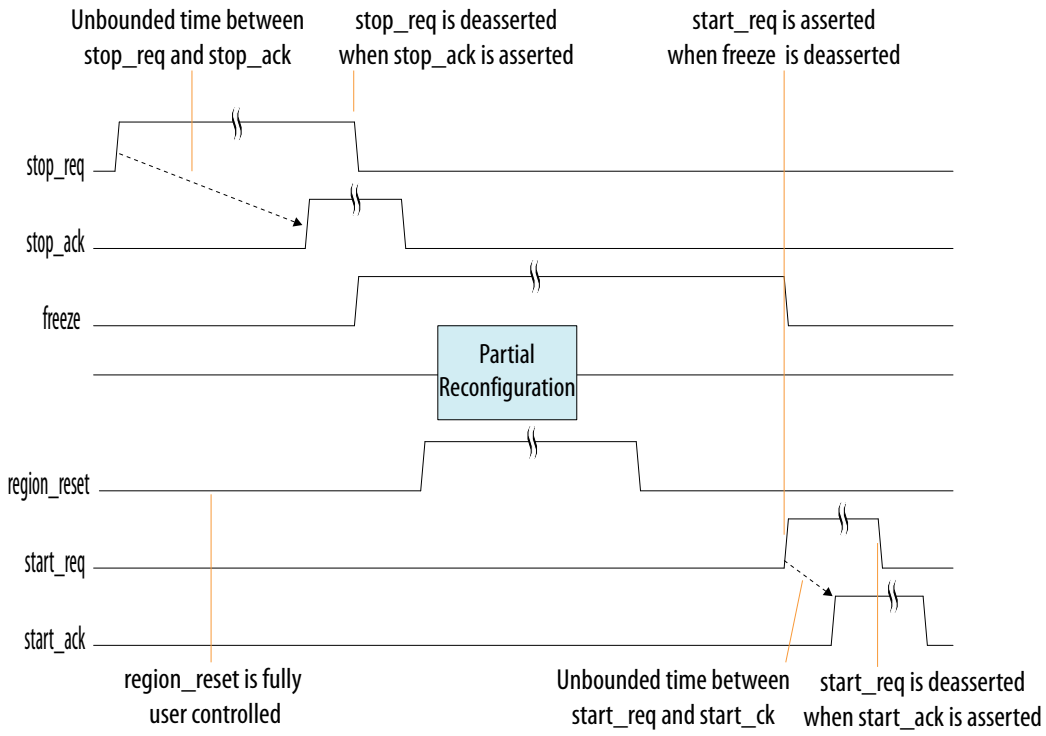
1.3. Partial Reconfiguration Process Sequence

Your partial reconfiguration design must initiate the PR operation and deliver the configuration file to the PR control block (Arria 10 and Cyclone 10 GX designs) or SDM (Agilex 7, Agilex 5, and Stratix 10 designs). Before partial reconfiguration, you must ensure that the FPGA device is in user mode, and in a functional state. The following steps describe the partial reconfiguration sequence:

1. Send the `stop_req` signal to the PR region from the sequential PR control logic to prepare for the PR operation. Upon receiving this signal, the PR regions complete any pending transactions and stop accepting new transactions.
2. Wait for the `stop_ack` signal to indicate that the PR region is ready for partial reconfiguration.
3. Use PR control logic to freeze all necessary outputs of the PR regions. Additionally, drive the clock enable for any initialized RAMs to a disabled state.
4. Send the PR bitstream to the PR control block (Arria 10 and Cyclone 10 GX designs) or SDM (Agilex 7, Agilex 5, and Stratix 10 designs) to initiate the PR process for the PR region. When using any of the Partial Reconfiguration Controller Intel FPGA IP, the Avalon® memory-mapped or Avalon streaming interface on the IP core provides this functionality. When directly instantiating the PR control block for Arria 10 designs, refer to PR Control Block Signal Timing Diagrams on page 103
5. On successful completion of the PR operation, reset the PR region.

6. Signal the start of PR operation by asserting the `start_req` signal, and deasserting the `freeze` signal.
7. Wait for the `start_ack` signal to indicate that the PR region is ready for operation.
8. Resume operation of the FPGA with the newly reconfigured PR region.

Figure 2. PR Process Sequence Timing Diagram



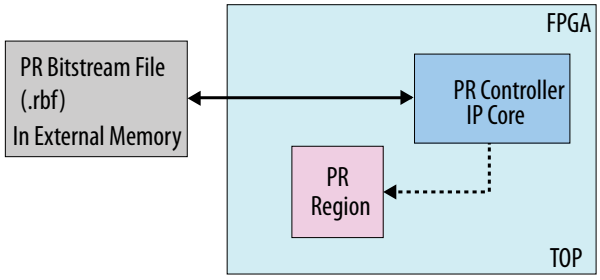
1.4. Internal Host Partial Reconfiguration

With internal host control, an internal controller, a Nios® II processor, or an interface such as PCI Express* (PCIe*) or Ethernet, communicates directly with the Arria 10 or Cyclone 10 GX PR control block, or with the SDM in Agilex 7, Agilex 5, and Stratix 10 devices.

To transfer the PR bitstream into the PR control block or SDM, you use the Avalon memory-mapped interface on the Partial Reconfiguration Controller IP core. When the device enters user mode, you initiate partial reconfiguration through the FPGA core fabric using the PR internal host.

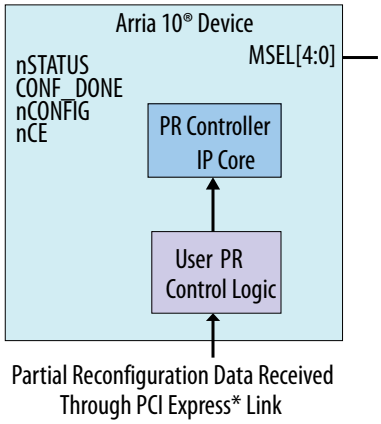
Note: If you create your own control logic for the PR host, the logic must meet the PR interface requirements.

Figure 3. Internal Host PR



When performing partial reconfiguration with an internal host, use the dedicated PR pins (PR_REQUEST, PR_READY, PR_DONE, and PR_ERROR) as regular I/Os. Implement your static region logic to retrieve the PR programming bitstreams from an external memory, for processing by the internal host.

Figure 4. Arria 10 FPGA System Using an Internal PR Host Example



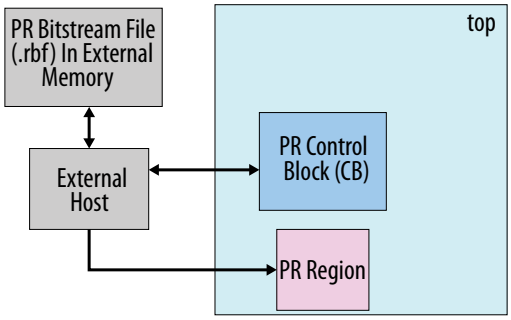
For example, send the programming bitstreams for partial reconfiguration through the PCI Express link. Then, you process the bitstreams with your PR control logic and send the bitstreams to the PR IP core for programming. nCONFIG moves the device out of the user mode into the device configuration mode.(1)

1.5. External Host Partial Reconfiguration

In external host control, an external FPGA or CPU controls the PR configuration using external dedicated PR pins on the target device. When using an external host, you must implement the control logic for transmission of the bitstream to the hard FPGA programming pins.

(1) nCONFIG can lock the device and force a power-cycle. PR programming may corrupt the static logic, due to improper use, causing disconnection of the core clock input to configuration block and unresponsive configuration. You must reset the PR IP before toggling nCONFIG.

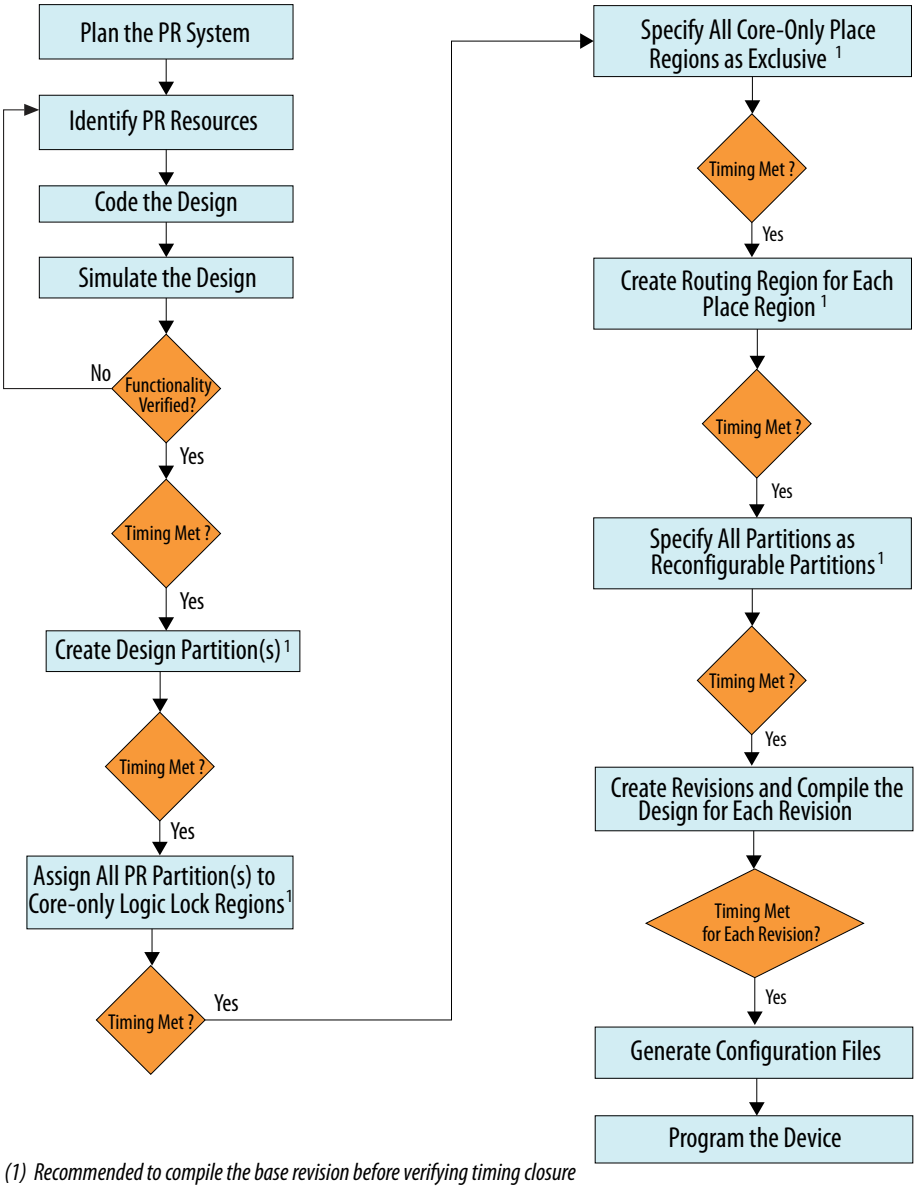
Figure 5. PR System Using an External Host (Arria 10 Example)



1.6. Partial Reconfiguration Design Flow

The PR design flow requires initial planning. This planning involves setting up one or more design partitions, and then determining the placement assignments in the floorplan. Well-planned PR partitions improve design area utilization and performance. The Quartus Prime software also allows you to create nested PR regions as part of an HPR flow.

Figure 6. Partial Reconfiguration Design Flow



(1) Recommended to compile the base revision before verifying timing closure

The PR design flow uses the project revisions feature in the Quartus Prime software. Your initial design is the base revision, where you define the static region boundaries and reconfigurable regions on the FPGA. From the base revision, you create multiple

revisions. These revisions contain the different implementations for the PR regions. However, all PR implementation revisions use the same top-level placement and routing results from the base revision.

The PR design flow includes the following steps:

1.6.1. Step 1: Identify Partial Reconfiguration Resources

When designing for partial reconfiguration, you must first determine the logical hierarchy boundaries that you can define as reconfigurable partitions. Reconfigurable partitions must contain only core resources, such as LABs, embedded memory blocks (M20Ks and MLABs), and DSP blocks in the FPGA.

All periphery resources, such as transceivers, external memory interfaces, GPIOs, I/O receivers, and the hard processor system (HPS), must be in the static region. Partial reconfiguration of global network buffers for clocks and resets is not possible.

Table 2. Supported Reconfiguration Methods

Hardware Resource Block	Reconfiguration Method
Logic Block	Partial reconfiguration
Digital Signal Processing	Partial reconfiguration
Memory Block	Partial reconfiguration
Core Routing	Partial reconfiguration
Transceivers/PLL	Dynamic reconfiguration
I/O Blocks	Not supported
Clock Control Blocks	Not supported

After identifying the resources for PR, set up the design hierarchy and source code to support this partitioning. Refer to Partial Reconfiguration Design Considerations on page 33.

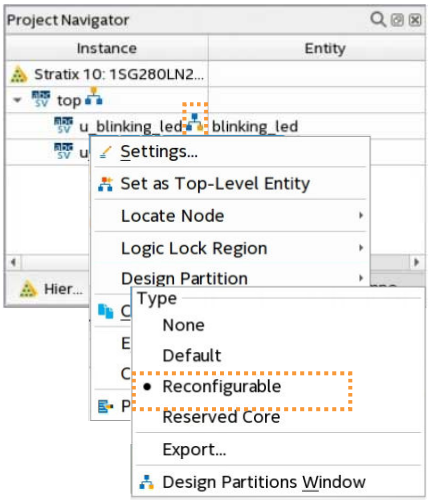
1.6.2. Step 2: Create Design Partitions

Create design partitions for each PR region that you want to partially reconfigure. Create any number of independent partitions or PR regions in your design. Create design partitions for partial reconfiguration from the Project Navigator, or the Design Partitions Window.

A design partition is only a logical partitioning of the design, and does not specify a physical area on the device. You associate a partition with a specific area of the FPGA using Logic Lock Region assignments. To avoid partitions obstructing design optimization, group the logic together within the same partition. If your design includes a hierarchical PR flow with parent and child partitions, you can define multiple parent or child partitions in your design, and multiple levels of PR partitions.

When you create a **Reconfigurable** partition, the Compiler preserves post-synthesis results for the partition and reuses the post-synthesis netlist, if you make no partition changes requiring re-synthesis. Otherwise, the Compiler resynthesizes the partition from source files. The Compiler adds wire LUTs for each interface of a **Reconfigurable** partition, and performs checks for PR compatibility.

Figure 7. Creating a Design Partition



Follow these steps to create design partitions:

1. Click **Processing ➤ Start ➤ Start Analysis & Elaboration**.
2. In the Project Navigator, right-click an instance in the **Hierarchy** tab, click **Design Partition ➤ Set as Design Partition**. A design partition icon appears next to each partition you create.
3. To view and edit all design partitions in the project, click **Assignments ➤ Design Partitions Window**.
4. Specify **Reconfigurable** as the partition **Type** for each PR partition. The **Reconfigurable** type preserves synthesis results, while allowing refit of the partition in the PR flow.

Figure 8. Design Partitions Window

Design Partitions Window

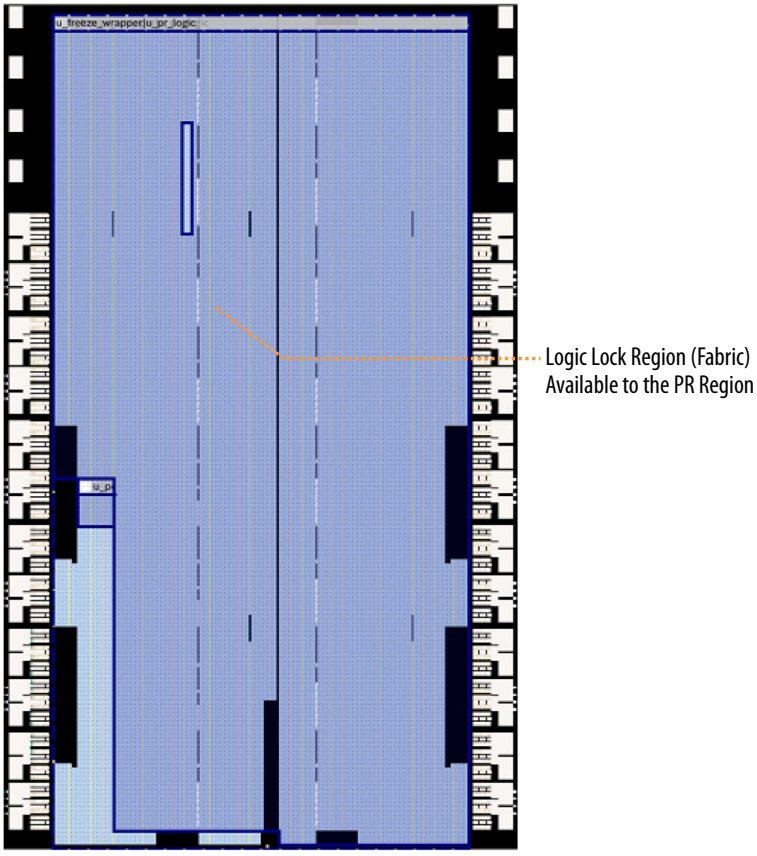
Assignments View | Compilation View

Partition Name	Hierarchy Path	Type	Preservation Level	Empty
<<new>>				
root_partition	|			
pr_partition	u_blinking_led	Reconfigurable	Not Set	No
supr_partition	u_top_counter	Reconfigurable	Not Set	No

1.6.3. Step 3: Floorplan the Design

Use Logic Lock floorplan constraints in your PR design to physically partition the device. Each PR partition in your design must have a corresponding, exclusive physical partition. You create Logic Lock regions to define the physical partition for your PR region. This partitioning ensures that the resources available to the PR region are the same for any persona that you implement.

Figure 9. PR Region Floorplan



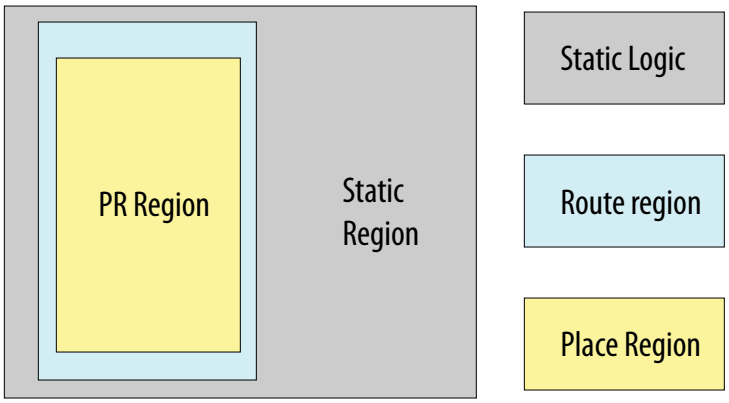
Your PR region must include only core logic, such as LABs, RAMs, ROMs, and DSPs in a PR region. Agilex 7, Agilex 5, and Stratix 10 designs can also include Hyper-Registers in the PR partition. Instantiate all periphery design elements, such as transceivers,

external memory interfaces, and clock networks in the static region of the design. The Logic Lock regions you create can cross periphery locations, such as the I/O columns and the HPS, because the constraint is core-only.

There are two region types:

- **Place regions**—use these regions to constrain logic to a specific area of the device. The Fitter places the logic in the region you specify. The Fitter can also place other logic in the region unless you designate the region as **Reserved**.
- **Route regions**—use these regions to constrain routing to a specific area. The routing region must fully enclose the placement region. Additionally, the routing regions for the PR regions cannot overlap.

Figure 10. Floorplanning your PR Design



Follow these guidelines when floorplanning your PR design:

- Complete the periphery and clock floorplan before core floorplanning. You can use Interface Planner (**Tools ➤ Interface Planner**) to create periphery floorplan assignments for your design.
- Define a routing region that is at least 1 unit larger than the placement region in all directions. In defining this region, avoid any overlapping routing regions between the static and PR regions.
- Do not overlap the routing regions of multiple PR regions.
- Select the PR region row-wise for least bitstream overhead. In Arria 10 and Cyclone 10 GX devices, short, wider regions generate smaller bitstreams than tall, narrower regions. Configuration occurs on sectors for Agilex 7, Agilex 5, and Stratix 10 devices. For the least bitstream overhead, ensure that you align the PR region to sector boundaries. Refer to "Analyzing and Optimizing the Design Floorplan," in *Quartus Prime Pro Edition User Guide: Design Optimization*.
- For Arria 10 and Cyclone 10 GX devices, the height of your PR region affects the reconfiguration time. A PR region larger in the Y direction takes longer to reconfigure. This condition does not apply to Agilex 7 or Stratix 10 devices because they configure according to sectors. The reconfiguration time of Agilex 7, Agilex 5, and Stratix 10 devices depends on the number of sectors the PR region covers. This reconfiguration time can also be affected by other factors, such as interleaving or the presence of other Logic Lock regions.

- To reduce programming files size for Agilex 7, Agilex 5, and Stratix 10 devices, target only the necessary number of sectors for PR. Also, ensure that the routing region of your PR region is 1 block (1 LAB row/column) inset from the edges of the clock sector boundaries.
- Define sub Logic Lock regions within PR regions to improve timing closure.
- If your design includes HPR parent and child partitions, the placement region of the parent region must fully enclose the routing and placement region of its child region. Also, the parent wire LUTs must be in an area outside the child PR region. This requirement is because the child PR region is exclusive to all other logic, which includes the parent and the static region.
- The base revision `.qdb` provides the only effective pin assignments for the implementation revision. Even if you subsequently change the pin assignments to the implementation revisions, those changes do not take effect.

1.6.3.1. Applying Floorplan Constraints Incrementally

PR implementation requires additional constraints that identify the reconfigurable partitions of the design and device. These constraints significantly impact the Compiler's timing closure ability. You can avoid and more easily correct timing closure issues by incrementally implementing each constraint, running the Compiler, then verifying timing closure.

Note: PR designs require a more constrained floorplan, compared to a flat design. The overall density and performance of a PR design may be lower than an equivalent flat design.

The following steps describe incrementally developing the requirements for your PR design:

1. Implement the base revision using the most complex persona for each PR partition. This initial implementation must include the complete design with all periphery constraints, and top-level `.sdc` timing constraints. Do not include any Logic Lock region constraints for the PR regions with this implementation.
2. Create partitions by setting the region **Type** option to **Default** in the Design Partitions Window, for all the PR partitions.
3. Register the boundaries of each partition to ensure adequate timing margin.
4. Verify successful timing closure using the Timing Analyzer.
5. Ensure that all the desired signals are driven on global networks. Disable the **Auto Global Clock** option in the Fitter (**Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**), to avoid promoting non-global signals.
6. Create Logic Lock core-only placement regions for each of the partitions.
7. Recompile the base revision with the Logic Lock constraints, and then verify timing closure.

8. Enable the **Reserved** option for each Logic Lock region to ensure the exclusive placement of the PR partitions within the placement regions. Enabling the **Reserved** option avoids placing the static region logic in the placement region of the PR partition.
9. Recompile the base revision with the **Reserved** constraint, and then verify timing closure.
10. In the Design Partitions Window, specify the **Type** for each of the PR partitions as **Reconfigurable**. This assignment ensures that the Compiler adds wire LUTs for each interface of the PR partition, and performs additional compilation checks for partial reconfiguration.
11. Recompile the base revision with the **Reconfigurable** constraint, and then verify timing closure. You can now export the top-level partition for reuse in the PR implementation compilation of the different personas.

1.6.4. Step 4: Add the Partial Reconfiguration Controller Intel FPGA IP

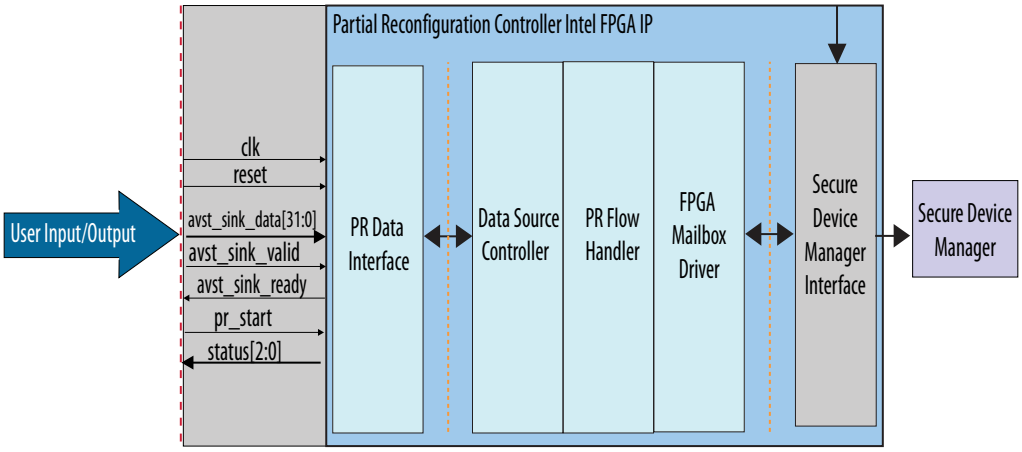
Depending on the target device family, you can add the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP or the Partial Reconfiguration Controller Intel FPGA IP to your design to send the partial reconfiguration bitstream to the PR control block or SDM in an internal host configuration.

1.6.4.1. Adding the Partial Reconfiguration Controller Intel FPGA IP

You can customize and instantiate the Partial Reconfiguration Controller Intel FPGA IP from the IP Catalog (**Tools ➤ IP Catalog**).

The Partial Reconfiguration Controller Intel FPGA IP interfaces with the Secure Device Manager (SDM) to manage the bitstream source. The SDM performs authentication and decompression on the configuration data. You can use this IP core in an Agilex 7, Agilex 5, or Stratix 10 design when performing partial reconfiguration with an internal PR host, Nios II processor, PCI Express, or Ethernet interface.

Figure 11. Partial Reconfiguration Controller (Avalon Streaming Interface)
(2)



(2) Avalon memory-mapped interface variant also available.

The Quartus Prime software supports PR over the core interface using the PR Controller IP core, or PR over the JTAG device pins. PR over JTAG pins does not require instantiation of the Partial Reconfiguration Controller Intel FPGA IP.

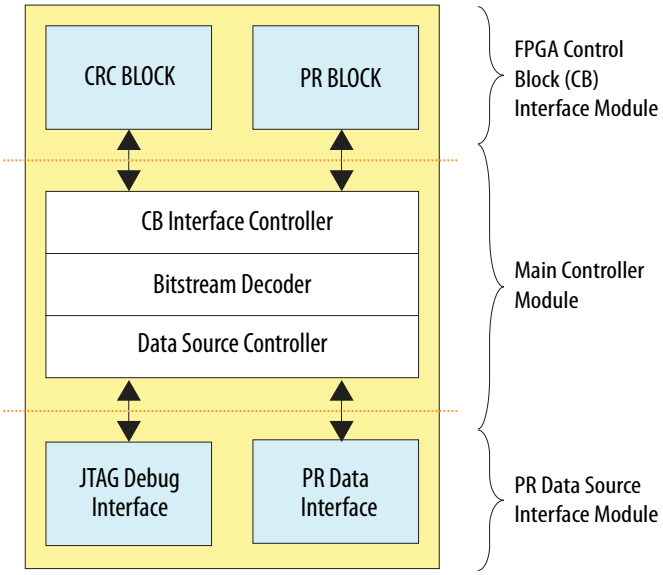
1.6.4.2. Adding the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP

The Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP interfaces with the Arria 10 or Cyclone 10 GX PR control block to manage the bitstream source.

Use this IP core in Arria 10 or Cyclone 10 GX designs when performing partial reconfiguration with an internal PR host, Nios II processor, PCI Express, or Ethernet interface.

During partial reconfiguration, you send a PR bitstream stored outside the FPGA to the PR control block inside the FPGA. This communication enables the control block to update the CRAM bits necessary for reconfiguring the PR region in the FPGA. The PR bitstream contains the instructions (opcodes) and the configuration bits necessary for reconfiguring a specific PR region.

Figure 12. Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP



Instantiate the IP core from the Quartus Prime IP Catalog (**Tools ➤ IP Catalog)** to automatically connect the IP to the Arria 10 or Cyclone 10 GX PR control block.

If you create your own custom logic to perform the function of the IP core, manually instantiate the control block to communicate with the FPGA system.

- PR Control Block and CRC Block Verilog HDL Manual Instantiation on page 100
- PR Control Block and CRC Block VHDL Manual Instantiation on page 100

1.6.5. Step 5: Define Personas

Your partial reconfiguration design can have multiple PR partitions, each with multiple personas. You define the unique function of each persona in separate Verilog HDL, SystemVerilog HDL, or VHDL design files in the project directory. All the PR personas must use the same set of signals to interact with the static region.

Ensure that the signals interacting with the static region are a super-set of all the signals in all the personas. A PR design requires an identical I/O interface for each persona in the PR region. If all personas for your design do not have identical interfaces, you must also create wrapper logic to interface with the static region.

Note: If using the Quartus Prime Text Editor, disable **Add file to current project** when saving the files. These persona source files should not be part of the Quartus Prime project or compilations.

1.6.6. Step 6: Create Revisions for Personas

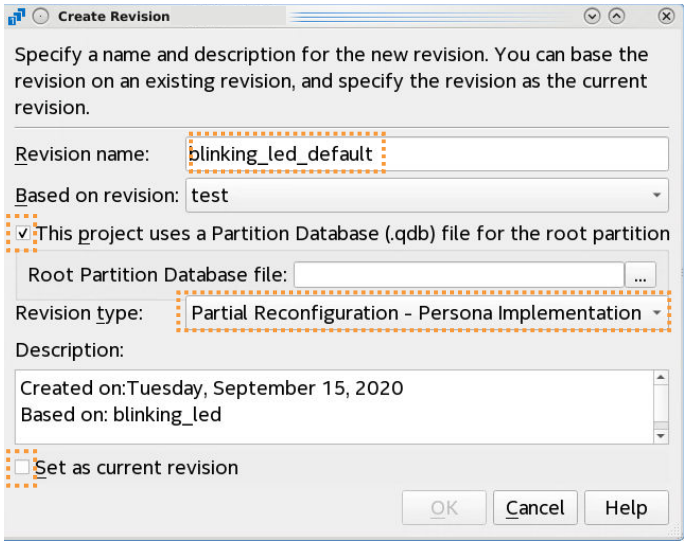
Create a base revision for the design, as well as PR implementation revisions for each of the personas. When you define revisions in the GUI or at the command line, the Quartus Prime software automatically adds these assignments required for PR implementation:

- Entity Rebinding assignment (`ENTITY_REBINDING`)—for each PR partition, the software adds an entity rebinding assignment with a place holder for the entity name. Your design may not require all of the entity rebinding assignments of each PR partition, based on the design and the implementation revision. For example, in HPR designs that use the default persona for the parent partition, you add the `.qdb` file for the PR parent, and then use entity rebinding only for the child.
- QDB File Partition assignment (`QDB_FILE_PARTITION`)—the software adds this assignment for the static region, if you specify a `.qdb` file name.
- Revision Type Assignment (`REVISION_TYPE`)

To create the PR implementation revisions:

1. Click **Project ➤ Revisions**.
2. To create a new revision, double-click **<<new revision>>**.
3. Specify a unique **Revision name**.
4. Select an existing revision for the **Based on revision** option.
5. For the **Revision type**, select **Partial Reconfiguration - Base** for the base revision or **Partial Reconfiguration - Persona Implementation** for an implementation revision.
6. Click **Apply** and **OK**.

Figure 13. Creating Revisions



The following assignments in the respective revision's `.qsf` file correspond to specifying the revision type from the **Settings** dialog box:

Base Revision Assignment:

```
set_global_assignment -name REVISION_TYPE PR_BASE
```

Implementation Revision Assignment:

```
set_global_assignment -name REVISION_TYPE PR_IMPL
```

For each PR partition, the Quartus Prime software also adds the entity rebinding assignment to the `.qsf`:

```
set_instance_assignment -name ENTITY_REBINDING <entity_name> -to
<hierarchical_path>
```

If you base a new implementation revision on an existing `.qdb` file, The Quartus Prime software also adds the `.qdb` file partition assignment, with a place holder for the file name:

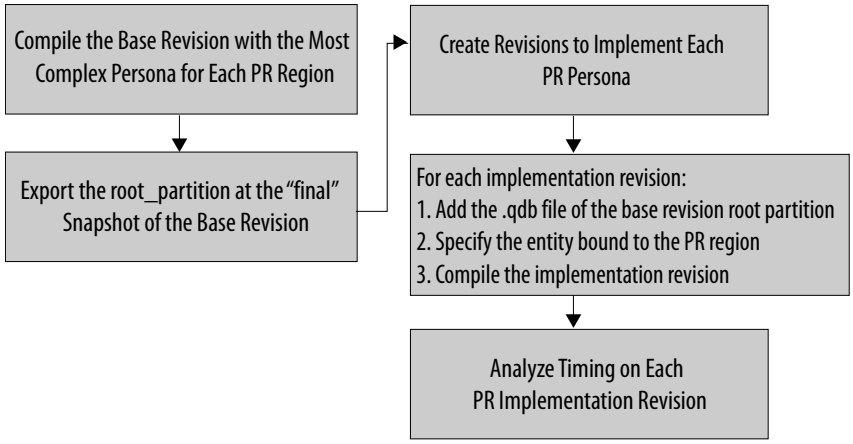
```
set_instance_assignment -name QDB_FILE_PARTITION <QDB file name>
```

As an example, to create a new implementation revision that uses a `.qdb` file from a base revision, use the following command:

```
create_revision impl_new -based_on <base_revision> \
     -new_rev_type impl -root_partition_qdb_file base_static.qdb
```

- `impl_new`—specifies the name of a new implementation revision.
- `-based_on <based_on_revision>` — specifies the PR base revision that the new `impl` revision is based on. Some global assignments from the `based_on` revision are copied over to the `impl` revision. Placeholder entity rebinding assignments are created in the `impl` revision for each PR partition in the base.
- `-new_rev_type <rev_type>`— only useful rev-type is `impl`.
- `root_partition_qdb_file <qdb_file>`—creates a `QDB_FILE_PARTITION` assignment in `impl` revision with the specified `.qdb` file.

Figure 14. Partial Reconfiguration Compilation Flow



1.6.7. Step 7: Compile the Base Revision and Export the Static Region

After defining and floorplanning PR partitions and revisions, you compile the base revision and export the static region. You can export individual design partitions manually, or you can export one or more partitions automatically each time you run the Compiler.

Follow these steps to compile and export the base and static region:

1. To specify the current revision, click **Project ➤ Revisions**, and then set the base revision as current, or select the base revision from the main toolbar drop-down list.
2. For Arria 10 and Cyclone 10 GX designs, you can optionally add the following assignments to the `.qsf` to automatically generate the required PR bitstreams following compilation. This step is not required for Agilex 7, Agilex 5, or Stratix 10 designs.

```
set_global_assignment -name GENERATE_PR_RBF_FILE ON
set_global_assignment -name ON_CHIP_BITSTREAM_DECOMPRESSION OFF
```

3. To compile the base revision, click **Processing ➤ Start Compilation**.
4. To export the static region, click **Project ➤ Export Design Partition** and specify options for the partition export:

Figure 15. Export Design Partition

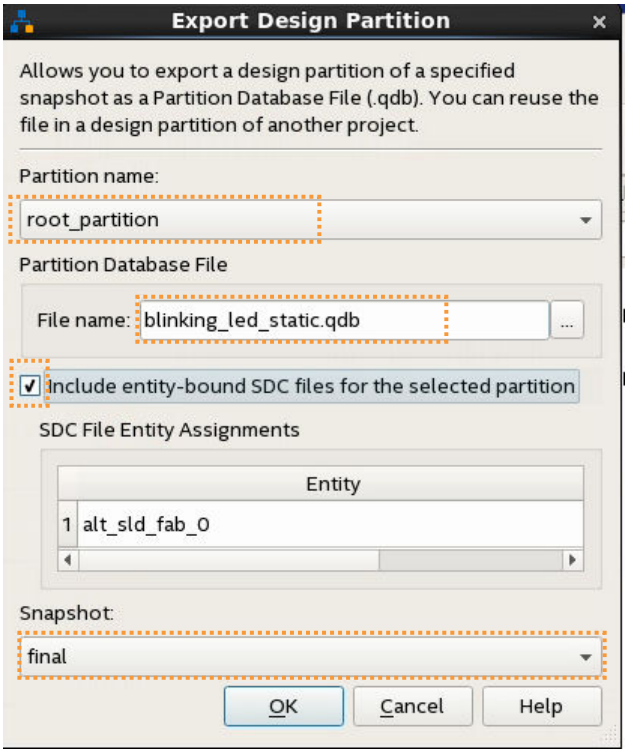


Table 3. Design Partition Options

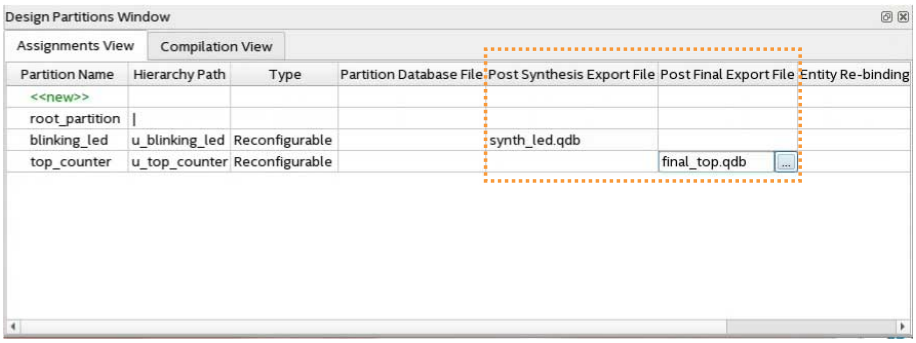
Option	Setting
Partition name	Select **root_partition**.
Partition database file	Specify a descriptive file name.
Include entity-bound SDC files	Enable to include entity bound `.sdc` files with the partition export. *Note:* You must enable this option when exporting the base revision (root partition), so that the implementation compiles inherit the timing constraints defined in entity-bound `.sdc` files.
Snapshot	Select **final** snapshot.

5. Alternatively, follow these steps to automatically export one or more design partitions after each compilation. You can automatically export any design partition that does not have a preserved parent partition, including the root_partition.
   a. To open the Design Partitions Window, click **Assignments ➤ Design Partitions Window**.
   b. To automatically export a partition with final snapshot results any time you run the Fitter, specify a `.qdb` file name for the **Post Final Export File** option for that partition.

Figure 16. Specifying Export File in Design Partitions Window



QSF File Equivalent:

```
set_instance_assignment -name \
     EXPORT_PARTITION_SNAPSHOT_<FINAL|SYNTHESIZED> \
     <hierarchy_path> -to <file_name>.qdb
```

1.6.7.1. Understanding PR Logic Utilization Reports

After running the Fitter compilation stage, you can view reports about the logic utilization of your PR design in the Compilation Report. The Partial Reconfiguration and Periphery Reuse Statistics report provides data about the boundary ports, ALMs, and other resources that the PR region requires.

This report may show an increase in the implementation revision ALM logic utilization compared with the base revision utilization. Specifically, the value of '`[C] estimate of the ALMs unavailable`' can be significantly higher in the implementation revision compared to the base revision, as the following figures illustrate.

Figure 17. Partial Reconfiguration and Periphery Reuse Statistics Report (Base Revision)

Partial Reconfiguration and Periphery Reuse Statistics

<<Filter>>

	Statistic	root_partition	pr_partition
1	Hierarchical Path	|	u_blinking_led
2			
3	▾ Boundary Ports	9	42
1	Input Ports	4	39
2	Output Ports	5	3
4			
5	Include Partial Reconfigurable Sub-blocks		
6	▾ ALMs needed [=A-B+C]	100.0 / 933120 (< 1 %)	20.5 / 3200 (< 1 %)
1	[A] ALMs used in final placement	117.0 / 933120 (< 1 %)	20.5 / 3200 (< 1 %)
2	[B] Estimate of ALMs recoverable by dense packing	17.0 / 933120 (< 1 %)	0.0 / 3200 (0 %)
3	[C] Estimate of ALMs unavailable	0.0 / 933120 (0 %)	0.0 / 3200 (0 %)

Figure 18. Partial Reconfiguration and Periphery Reuse Statistics Report (Implementation Revision)

Partial Reconfiguration and Periphery Reuse Statistics

<<Filter>>

	Statistic	root_partition	pr_partition
1	Hierarchical Path	|	u_blinking_led
2			
3	▾ Boundary Ports	9	42
1	Input Ports	4	39
2	Output Ports	5	3
4			
5	Include Partial Reconfigurable Sub-blocks		
6	▾ ALMs needed [=A-B+C]	519.3 / 933120 (< 1 %)	344.3 / 3200 (10 %)
1	[A] ALMs used in final placement	498.5 / 933120 (< 1 %)	402.0 / 3200 (12 %)
2	[B] Estimate of ALMs recoverable by dense packing	71.9 / 933120 (< 1 %)	58.9 / 3200 (1 %)
3	[C] Estimate of ALMs unavailable	92.7 / 933120 (< 1 %)	1.2 / 3200 (< 1 %)

This increase in ALM usage appears because the base revision compilation report reflects logic utilization that is based only on the base revision RTL file. However, for the implementation revision, the static region is imported from the base revision `.qdb` file that also includes all of the logic (used and unused) of the static region. This additional base revision logic causes the increase in `[C]`. In this case, `[C]` includes every ALM of the static region `.qdb` file. In contrast, `[A]` is the actual number of used ALMs in the design after placement. For the Total Logic Utilization of PR designs, you must review the `[A]ALMs used in final placement`.

1.6.8. Step 8: Setup PR Implementation Revisions

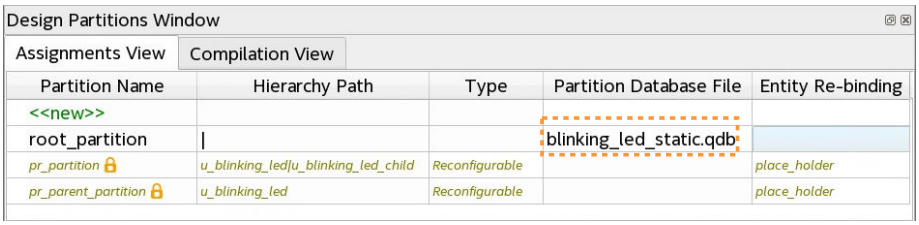
You must prepare the PR implementation revisions before you can generate the PR bitstream for device programming. This setup includes adding the static region `.qdb` file as the source file for each implementation revision. In addition, you must specify the corresponding entity of the PR region.

Note: The base revision `.qdb` provides the only effective pin assignments for the implementation revision. Even if you subsequently change the pin assignments in the implementation revision `.qsf`, those changes do not take effect.

Follow these steps to setup the PR implementation revisions:

1. Set an implementation revision as the **Current Revision**.
2. To specify the `.qdb` file as the source for `root_partition`, click **Assignments ➤ Design Partitions Window**. Double-click the **Partition Database File** cell and specify the appropriate `.qdb` file.
3. For each PR implementation revision, specify the name of the entity that you want to partially reconfigure in the **Entity Re-binding cell**. This entity name comes from the design file for the persona you want to implement in this implementation revision.

Figure 19. Design Partitions Window



4. To compile the design, click **Processing ➤ Start Compilation**.
5. Repeat steps 1 through 4 to setup and compile each implementation revision. Alternatively, use a simple Tcl script to compile all implementation revisions:

```
set_current_revision <implementation1 revision name>
execute_flow -compile
set_current_revision <implementation2 revision name>
execute_flow -compile
.
.
.
```

Note: When you generate a static `.qdb` for import into a PR implementation compile, make sure to preserve the entity-bound `.sdc` files for the static partition. Also, for the implementation revision to properly process the `.sdc` files, the order of assignments in the implementation file `.qsf` is very important. Verify the order of the `.sdc` files in the implementation revision. The implementation revision includes the entity-bound `.sdc` constraints pulled in by the static region `.qdb`. The implementation revision also includes the `.sdc` files for the implementation revision. If you require the `.sdc` files pulled in by the static region `.qdb` before the implementation revision `.sdc` files, ensure that the `QDB_FILE_PARTITION` assignment appears before any other `.sdc` file assignment.

1.6.9. Step 9: Program the FPGA Device

The Quartus Prime Assembler generates the PR bitstreams for your design personas. For Arria 10 and Cyclone 10 GX designs, you send the bitstreams to the PR control block. For Agilex 7, Agilex 5, and Stratix 10 designs, you send the PR bitstreams to the SDM. You must compile the PR project, including the base revision, and at least one implementation revision, before generating the PR bitstreams.

For Agilex 7, Agilex 5, and Stratix 10 designs, the Assembler generates a configuration `.rbf` automatically at the end of compilation. For Arria 10 and Cyclone 10 GX designs, you can add the GENERATE_PR_RBF_FILE assignment to the `.qsf` or use the **Convert Programming Files** dialog box to convert the Partial-Masked SRAM Object Files (`.pmsf`) to an `.rbf` file, as Generating PR Bitstream Files on page 28 describes.

Figure 20. Programming File Generation

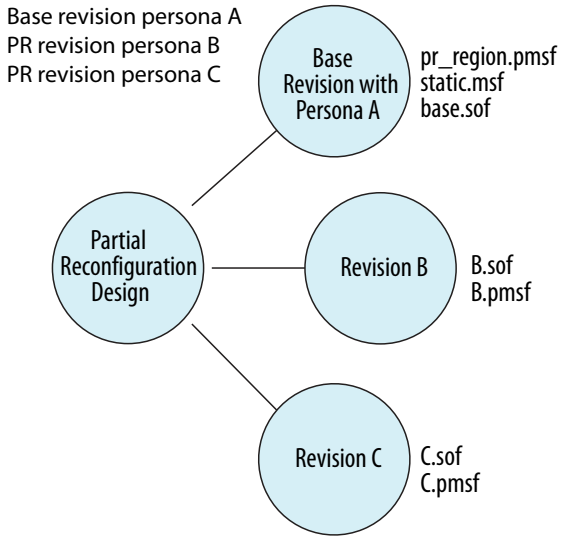


Table 4. PR Programming Files

Programming File	Description
`<rev>.<pr_region>.pmsf`	Contains the partial-mask bits for the PR region. The `.pmsf` file contains all the information for creating PR bitstreams. *Note:* The default file name corresponds to the partition name.
`<rev>.<static_region>.msf`	Contains the mask bits for the static region.
`<rev>.sof`	Contains configuration information for the entire device.

1.6.9.1. Generating PR Bitstream Files

For Agilex 7, Agilex 5, and Stratix 10 designs, the Assembler generates a configuration `.rbf` automatically at the end of compilation. For Arria 10 and Cyclone 10 GX designs, use any of the following methods to process the PR bitstreams and generate the Raw Binary File (`.rbf`) file for reconfiguration.

Note: The Assembler generates a configuration `.rbf` automatically at the end of compilation for Agilex 7, Agilex 5, and Stratix 10 designs. You do not need to separately generate these files when targeting these devices.

Generating PR Bitstreams During Compilation (Arria 10 and Cyclone 10 GX Designs)

Follow these steps to generate the `.rbf` file during compilation for Arria 10 and Cyclone 10 GX designs:

1. Add the following assignments to the revision `.qsf` to automatically generate the required PR bitstreams following compilation:

```
set_global_assignment -name GENERATE_PR_RBF_FILE ON
set_global_assignment -name ON_CHIP_BITSTREAM_DECOMPRESSION OFF
```

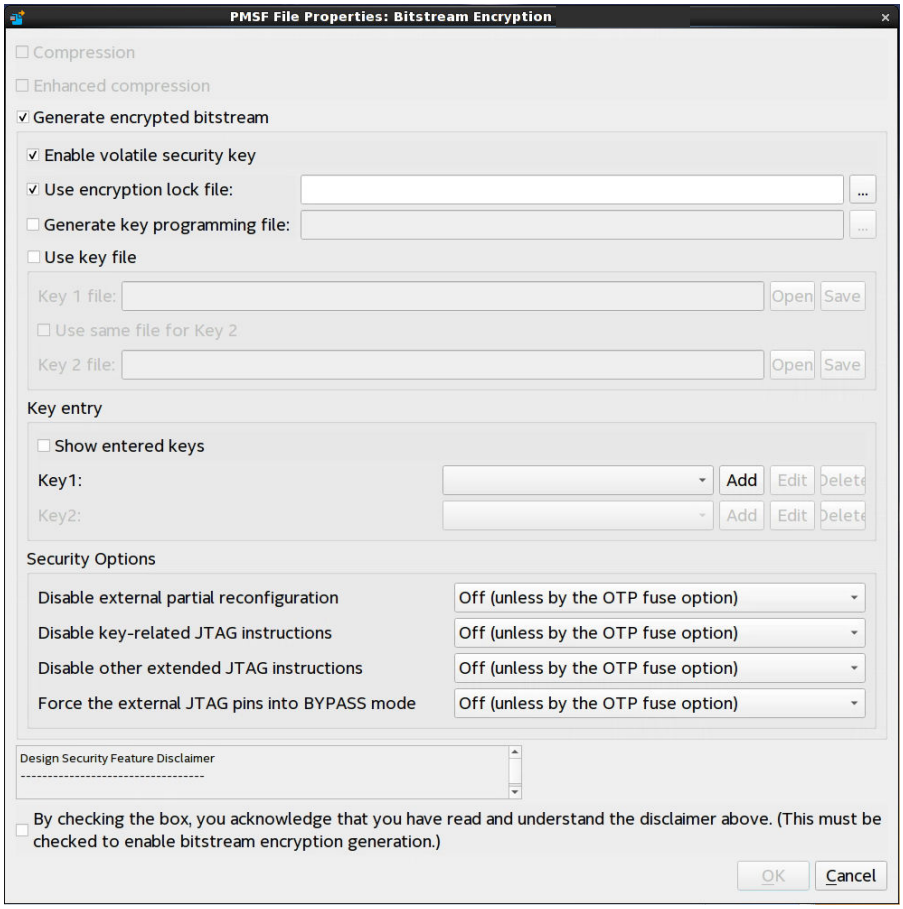
2. To compile the revision and generate the `.rbf`, click **Processing ➤ Start Compilation**.

Generating PR Bitstreams with Convert Programming Files Dialog Box (Arria 10 and Cyclone 10 GX Designs)

Follow these steps to generate the `.rbf` with the **Convert Programming Files** dialog box:

1. Click **File ➤ Convert Programming Files**. The **Convert Programming Files** dialog box appears.
2. Specify the output file name and **Programming file type** as **Raw Binary File for Partial Reconfiguration (.rbf)**.
3. To add the input `.pmsf` file to convert, click **Add File**.
4. Select the newly added `.pmsf` file, and click **Properties**.
5. Enable or disable any of the following options and click **OK**:
   - **Compression**—enables compression on PR bitstream.
   - **Enhanced compression**—enables enhanced compression on PR bitstream.
   - **Generate encrypted bitstream**—generates encrypted independent bitstreams for base image and PR image. You can encrypt the PR image even if your base image has no encryption. The PR image can have a separate encryption key file (`.ekp`). If you enable **Generate encrypted bitstream**, enable or disable the **Enable volatile security key**, **Use encryption lock file**, and **Generate key programming file** options.
6. Click **Generate**. The PR bitstream files generate according to your specifications.

Figure 21. PMSF File Properties Bitstream Encryption



1.6.9.2. Generating PR Bitstream Files

For Agilex 7, Agilex 5, and Stratix 10 designs, the Assembler generates a configuration `.rbf` automatically at the end of compilation. For Arria 10 and Cyclone 10 GX designs, use any of the following methods to process the PR bitstreams and generate the Raw Binary File (`.rbf`) file for reconfiguration.

Generating PR Bitstreams During Compilation

Follow these steps to generate the `.rbf` file during compilation for Arria 10 and Cyclone 10 GX designs:

1. Add the following assignments to the revision `.qsf` to automatically generate the required PR bitstreams following compilation:

```
set_global_assignment -name GENERATE_PR_RBF_FILE ON
set_global_assignment -name ON_CHIP_BITSTREAM_DECOMPRESSION OFF
```

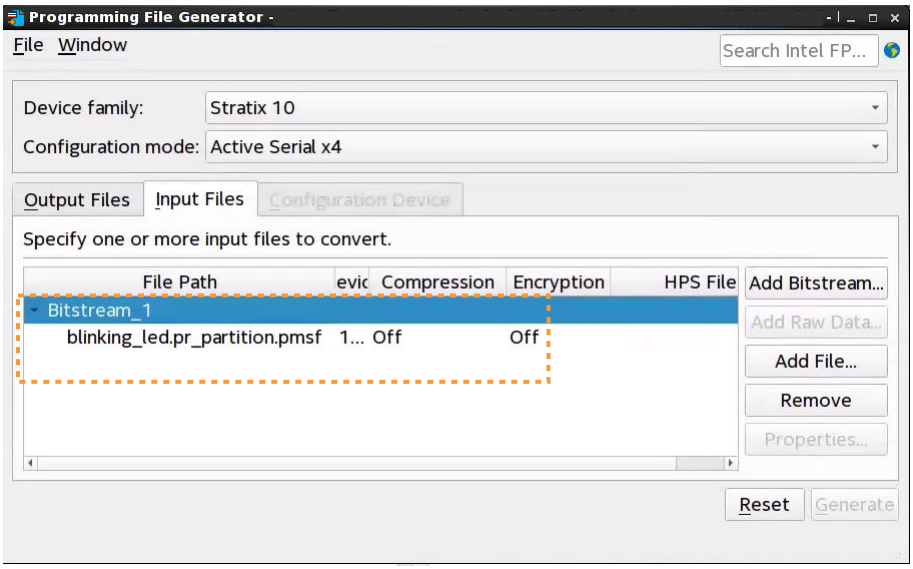
2. To compile the revision and generate the `.rbf`, click **Processing ➤ Start Compilation**.

Generating PR Bitstreams with Programming File Generator

Follow these steps to generate the `.rbf` for PR programming with the **Programming File Generator**:

1. Click **File ➤ Programming File Generator**. The **Programming File Generator** appears.
2. Specify the target **Device family** and the **Configuration mode** for partial reconfiguration.
3. On the **Output File** tab, specify the **Output directory**, file **name**, and enable the **Raw Binary File for Partial Reconfiguration (.rbf)** file type.
4. To add the input `.pmsf` file to convert, click the **Input Files** tab, click **Add Bitstream**, and specify the `.pmsf` that you generated in the Assembler.

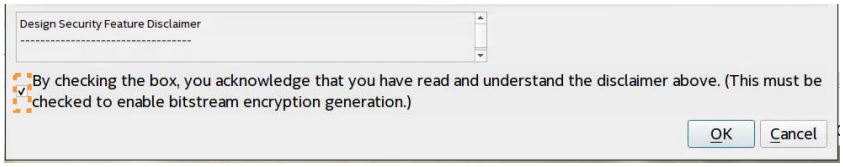
Figure 22. Adding Bitstream File



5. On the **Input Files** tab, select the bitstream `.pmsf` file and click **Properties**. Specify any of the following options for the `.rbf`:

- **Enable compression**—generates compressed PR bitstream files to reduce file size.
- **Enable encryption**—generates encrypted independent bitstreams for base image and PR image. You can encrypt the PR image even if your base image has no encryption. The PR image can have a separate encryption key file (`.ekp`). You can also specify other **Security settings**.
- If you turn on **Enable encryption**, you must also acknowledge the **Design Security Feature Disclaimer** by checking the box.

Figure 23. Design Security Feature Disclaimer



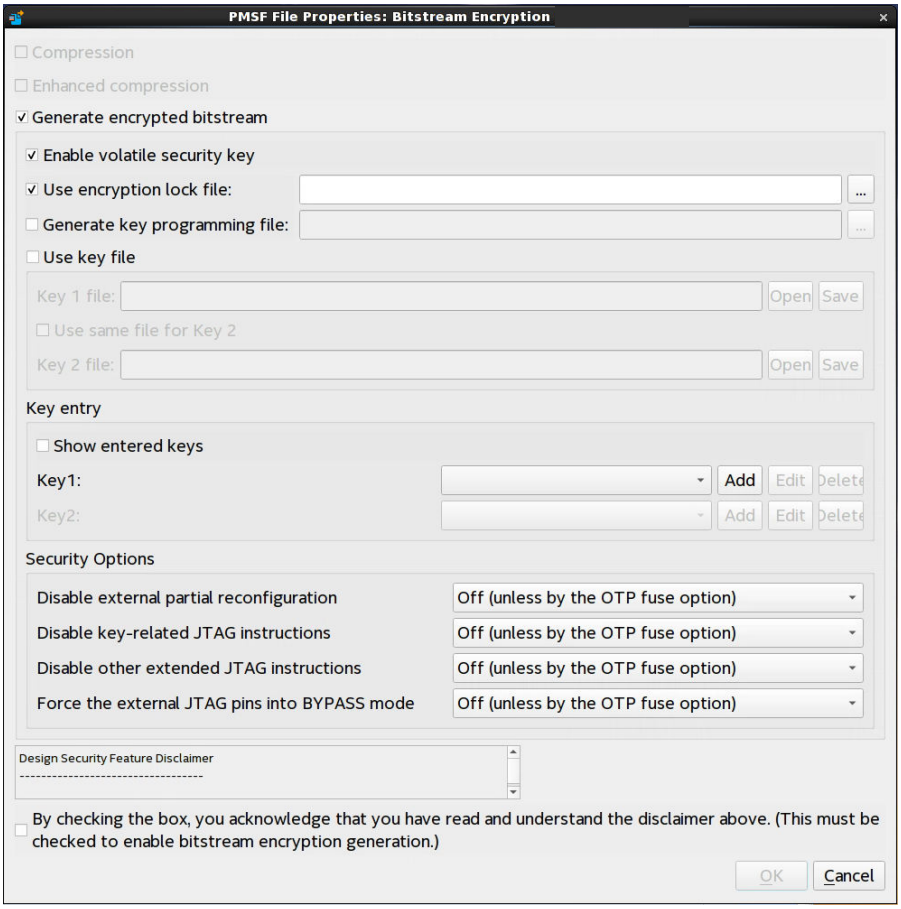
6. Click **OK**.
7. In **Programming File Generator**, click **Generate**. The PR bitstream files generate according to your specifications.

Generating PR Bitstreams with Convert Programming Files Dialog Box

Follow these steps to generate the `.rbf` with the **Convert Programming Files** dialog box:

1. Click **File ➤ Convert Programming Files**. The **Convert Programming Files** dialog box appears.
2. Specify the output file name and **Programming file type** as **Raw Binary File for Partial Reconfiguration (.rbf)**.
3. To add the input `.pmsf` file to convert, click **Add File**.
4. Select the newly added `.pmsf` file, and click **Properties**.
5. Enable or disable any of the following options and click **OK**:
   - **Compression**—enables compression on PR bitstream.
   - **Enhanced compression**—enables enhanced compression on PR bitstream.
   - **Generate encrypted bitstream**—generates encrypted independent bitstreams for base image and PR image. You can encrypt the PR image even if your base image has no encryption. The PR image can have a separate encryption key file (`.ekp`). If you enable **Generate encrypted bitstream**, enable or disable the **Enable volatile security key**, **Use encryption lock file**, and **Generate key programming file** options.
6. Click **Generate**. The PR bitstream files generate according to your specifications.

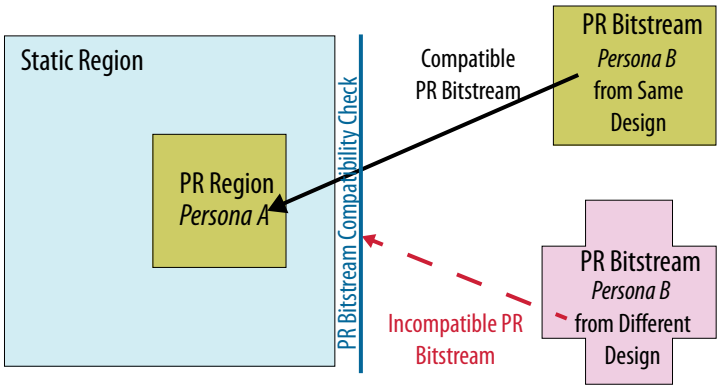
Figure 24. PMSF File Properties Bitstream Encryption



1.6.9.3. Partial Reconfiguration Bitstream Compatibility Checking

Partial reconfiguration bitstream compatibility checking verifies the compatibility of the reconfiguration bitstream to prevent configuration with an incompatible PR bitstream. The following sections describe PR bitstream compatibility check support.

Figure 25. PR Bitstream Compatibility Checking



PR Bitstream Compatibility Checking for Agilex 7, Agilex 5, and Stratix 10 Designs

For Agilex 7, Agilex 5, and Stratix 10 designs, PR bitstream compatibility checking is automatically enabled in the Compiler and in the Secure Device Manager (SDM) firmware by default. The following limitations apply to PR designs *if PR bitstream compatibility checking is enabled*:

- The firmware allows up to a total of 32 PR regions, irrespective of the number of hierarchical partial reconfiguration layers.
- Your PR design can have up to six hierarchical partial reconfiguration layers.
- Your PR design, when there is no hierarchy, can have up to 32 regions.
- Your PR design can have up to 15 child PR regions of any parent PR region (if it is hierarchical). Child PR regions count towards the total limit of 32 PR regions.

The Compiler generates an error if your PR design exceeds these limits when PR bitstream compatibility checking is enabled.

If you require more PR regions than this limitation allows, or otherwise want to disable PR bitstream compatibility checking , you can add the following assignment to the `.qsf` file:

```
set_global_assignment -name ENABLE_PR_POF_ID OFF
```

When you set this assignment to off, the limit of 32 total regions does not apply in the Compiler.

Note: If you require the PR bitstream authentication feature for your design, you must enable PR bitstream compatibility checking by setting the global assignment `ENABLE_PR_POF ID` to `ON`. The default setting is `ON`.

Arria 10 and Cyclone 10 GX PR Bitstream Compatibility Checking

For Arria 10 and Cyclone 10 GX designs, you enable or disable PR bitstream compatibility checking by turning on the **Enable bitstream compatibility check** option when instantiating the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP from the IP Catalog.

The PR IP verifies the partial reconfiguration PR Bitstream file (`.rbf`). When you enable the bitstream compatibility check, the PR `.pof` ID is encoded as the 71st word of the PR bitstream. If the PR IP detects an incompatible bitstream, then the PR IP stops the PR operation, and the status output reports an error.

When you turn on **Enable bitstream compatibility check**, the PR Controller IP core creates a **PR bitstream ID** and displays the bitstream ID in the configuration dialog box. For bitstream compatibility checking with hierarchical PR designs, refer to additional steps in *AN 806: Hierarchical Partial Reconfiguration Tutorial for Arria 10 GX FPGA Development Board*.

1.6.9.4. Raw Binary Programming File Byte Sequence Transmission Examples

The raw binary programming file (`.rbf`) file contains the device configuration data in little-endian raw binary format. The following example shows transmitting the `.rbf` byte sequence 02 1B EE 01 in x32 mode:

Table 5. Writing to the PR control block or SDM in x32 mode

In x32 mode, the first byte in the file is the least significant byte of the configuration double word, and the fourth byte is the most significant byte.

Double Word = 01EE1B02			
LSB: BYTE0 = 02	BYTE1 = 1B	BYTE2 = EE	MSB: BYTE3 = 01
D[7..0]	D[15..8]	D[23..16]	D[31..24]
0000 0010	0001 1011	1110 1110	0000 0001

1.6.9.5. Generating a Merged .pmsf File from Multiple .pmsf Files (Arria 10 and Cyclone 10 GX Designs)

Use a single merged `.rbf` file to reconfigure two PR regions simultaneously.

Note: This procedure supports only Arria 10 and Cyclone 10 GX devices. Agilex 7, Agilex 5, and Stratix 10 devices do not support merging `.pmsf` files.

To merge two or more `.pmsf` files:

1. Open the **Convert Programming Files** dialog box.
2. Specify the output file name and programming file type as **Merged Partial-Mask SRAM Object File (.pmsf)**.
3. In the **Input files to convert** dialog box, select **PMSF Data**.
4. To add input files, click **Add File**. You must specify two or more files for merging.
5. To generate the merged file, click **Generate**.

Alternatively, to merge two or more `.pmsf` files from the Quartus Prime shell, type the following command:

```
quartus_cpf --merge_pmsf=<number of merged files> <pmsf_input_file_1> \
     <pmsf_input_file_2> <pmsf_input_file_etc> <pmsf_output_file>
```

For example, to merge two `.pmsf` files, type the following command:

```
quartus_cpf --merge_pmsf=2 foo.pmsf bat.pmsf \
     combine.pmsf
```

After creating the merged `.pmsf`, generate a `.rbf`, as Generating PR Bitstream Files on page 28 describes.

1.7. Partial Reconfiguration Design Considerations

Partial reconfiguration is an advanced design flow in the Quartus Prime Pro Edition software. Creating a partial reconfiguration design requires an understanding of how the PR design guidelines apply to your design. When designing for partial reconfiguration, you must consider the entire system-level behavior initial conditions to maintain the integrity and correctness of the static region operation.

For example, during PR programming, you must ensure that other parts of the system do not read or write to the PR region. You must also freeze the write enable output from the PR region into the static region, to avoid interference with static region operation. If all personas for your design do not have identical top-level interfaces, you must create the wrapper logic to ensure that all the personas appear similar to the static region. Upon partial reconfiguration of a PR region, you must bring the registers in the PR region to a known state by applying a reset sequence. There are specific guidelines for global signals and on-chip memories. The following sections provide design considerations and guidelines to help you create design files for a PR design.

FPGA Device and Software Considerations

- All Agilex 7, Agilex 5, Stratix 10, Arria 10, and Cyclone 10 GX devices support partial reconfiguration.
- Use the nominal VCC of 0.9V or 0.95V as per the datasheet, including VID enabled devices.
- To minimize Arria 10 and Cyclone 10 GX programming files size, ensure that the PR regions are short and wide. For Agilex 7, Agilex 5, and Stratix 10 designs, use sector-aligned PR regions.
- The Quartus Prime Standard Edition software does not support partial reconfiguration for Arria 10 devices, nor provide any support for Agilex 7, Agilex 5, or Stratix 10 devices.
- The current version of the Quartus Prime Pro Edition software supports only one Signal Tap File (`.stp`) per revision.

Design Partition Considerations

- Reconfigurable partitions can only contain core resources, such as LABs, RAMs, and DSPs. All periphery resources, such as the transceivers, external memory interface, HPS, and clocks must be in the static portion of the design.
- To physically partition the device between static and individual PR regions, floorplan each PR region into exclusive, core-only, placement regions, with associated routing regions.
- A reconfiguration partition must contain the super-set of all ports that you use across all PR personas.

Clocking, Reset, and Freeze Signal Considerations

- The maximum number of clocks or other global signals for any Arria 10 or Cyclone 10 GX PR region is 33. The maximum number of clocks or other global signals for any Agilex 7, Agilex 5, and Stratix 10 PR region is 32. In the current version of the Quartus Prime Pro Edition software, no two PR regions can share a row-clock.
- PR regions do not require any input freeze logic. However, you must freeze all the outputs of each PR region to a known constant value to avoid unknown data during partial reconfiguration.
- Increase the reset length by 1 cycle to account for register duplication in the Fitter.
- Ensure that all low-skew global signals (clocks and resets) driving into PR regions in base revision compilations have destinations.
- In Agilex 7 and Agilex 5 devices, you must use global clock resources to clock M20K RAMs in PR regions. The Fitter issues an error if an M20K in a PR region is driven by a clock port from a locally routed clock.

1.7.1. Partial Reconfiguration Design Guidelines

The following table lists important design guidelines at various steps in the PR design flow:

Table 6. Partial Reconfiguration Design Guidelines

PR Design Step	Guideline	Reason
Designing for partial reconfiguration	Do not assume initial states in registers inside PR region. After PR is complete, reset all the control path registers to a known state. Unless required for your scenario, you can omit the data path registers from the reset.	Registers inside the PR region contain undefined values after reconfiguration. Omitting data path registers reduces congestion on reset signals. However, resetting the data registers is required in some cases.(3)
	You cannot define synchronous reset as a global signal for Arria 10 or Cyclone 10 GX partial reconfiguration.	PR regions do not support synchronous reset of registers as a global signal, because the Arria 10 and Cyclone 10 GX LAB does not support synchronous clear (`sclr`) signal on a global buffer. The LAB supports the asynchronous clear (`aclr`) signal driven from a local input, or from a global network row clock. As a result, only the `aclr` can be a global signal, feeding registers in a PR region.
	The PRESERVE_FANOUT_FREE_NODE assignment cannot preserve a fanout-free register that has no fanout inside the Verilog HDL or VHDL module in which you define it. To preserve these fanout-free registers, implement the `noprune` pragma in the source file: `(*noprune*)reg r;` If there are multiple instances of this module, with only some instances requiring preservation of the fanout-free register, set a dummy pragma on the register in the HDL and also set the PRESERVE_FANOUT_FREE_NODE assignment. This dummy pragma allows the register synthesis to implement the assignment. For example, set the following dummy pragma for a register `r` in Verilog HDL: `(*dummy*)reg r;` Then set this instance assignment: `set_instance_assignment -name \ PRESERVE_FANOUT_FREE_NODE ON \ -to r;`	The PRESERVE_FANOUT_FREE_NODE assignment does not apply when a register is not used in the Verilog HDL or VHDL module in which it is defined.
Partitioning the design	Register all the inputs and outputs for your PR region.	Improves timing closure and time budgeting.

continued...

(3) For example, there are occurrences where registers are being duplicated while simultaneously the register value is undefined after PR. The duplicated registers can result in a mismatch between the parity bit and the data written to the MLAB after PR. Hence, a different value is used to compute the parity bit compared with the actual data written to the MLAB, requiring reset of the data register, or re-write of the value to the register after PR.

PR Design Step	Guideline	Reason
	Reduce the number of signals interfacing the PR region with the static region in your design.	Reduces the wire LUT count.
	Create a wrapper for your PR region.	The wrapper creates a common footprint to the static region.
	Drive all the PR region output ports to inactive state when the PR region is held in reset and the freeze bit is asserted for the PR region.	Prevents the static region logic from receiving random data during the partial reconfiguration operation.
	PR boundary I/O interface must be a superset of all the PR persona I/O interfaces.	Ensures that each PR partition implements the same ports.
Preparing for partial reconfiguration	Complete all pending transactions.	Ensures that the static region is not in a wait state.
Maintaining a partially working system during partial reconfiguration	Hold all outputs to known constant values.	Ensures that the undefined values the PR region receives during and after the reconfiguration do not affect the PR control logic.
Initializing after partial reconfiguration	Initialize after reset.	Retrieves state from memory or other device resources.
Debugging the design using Signal Tap Logic Analyzer	Store all the tapped signals from a persona in one `.stp` file.	The current version of the Quartus Prime software supports only one `.stp` (Signal Tap file) per revision. This limitation requires you to select partitions, one at a time, to tap.
	Do not tap across regions in the same `.stp` file.	Ensures consistent interface (boundary) across all personas.
	Tap only the pre-synthesis signals. In the Node Finder, filter for **Signal Tap: pre-synthesis**.	Ensures that the signal tapping of PR personas start from synthesis.

1.7.2. PR Design Timing Closure Best Practices

The use of partition boundary ports for PR regions can make timing closure more challenging because the Compiler cannot optimize the logic across a partition boundary. The use of Logic Lock regions can also limit placement and routing flexibility. You must register all PR region boundary ports. Even when taking these steps, you may still find timing criticalities.

Each persona of a PR region can have different bits or input and output buses in use. Therefore, it is important to preserve the registers that do not have fan-out in a given persona, or that are driven by constants. You must ensure that the Compiler does not optimize away such registers during the compilation of a persona.

If the base compile does not use some bits of a bus, and the Compiler removes the corresponding registers for those bits, the logic may be untimed, resulting in unfavorable placement and routing. If you use those unregistered paths in other persona logic, you can have difficulty meeting timing on those paths. Preserving the unused port registers in the base compile ensures that the paths are timed in the base compile, and eases timing closure during persona compiles.

Follow these guidelines for effective register preservation in PR designs:

- Only the registers within PR regions require preservation.
- Only the PR base compilation requires register preservation.
- In a persona compile, the Compiler can safely remove fan-out free and constant-driven registers.
- For hierarchical PR compilations, only the base compile of the hierarchy requires register preservation.
- Preserve fan-out free nodes for input registers.
- Preserve constant-driven nodes for output registers.
- Only assign the attributes for the PR base compile. Remove the attributes for the persona compile (for example, via parameter or generic).
- You can set top-level parameters in the `.qsf`, which in turn pass down to lower hierarchies.

Use any of the following synthesis attributes to preserve registers:

- To preserve constant-driven or fan-out free registers, use the `noprune` attribute. `noprune` also disables all physical optimizations:

```
Verilog: (* noprune *) reg reg1;
VHDL: signal reg1: std_logic;
      attribute noprune: boolean;
      attribute noprune of reg1: signal is true;
```

- To preserve fan-out free registers while allowing retiming on bits that have fan-outs, assign PRESERVE_FANOUT_FREE_NODE ON as `altera_attribute`:

```
Verilog: (* altera_attribute = "-name PRESERVE_FANOUT_FREE_NODE ON" *) \
     reg reg1;
VHDL: signal reg1: stdlogic;
      attribute altera_attribute : string;
      attribute altera_attribute of reg1: signal is "-name \
     PRESERVE_FANOUT_FREE_NODE ON";
```

- Alternatively, use the `dummy` attribute with the PRESERVE_FANOUT_FREE_NODE ON assignment in the `.qsf`:

```
Verilog: (* dummy *) reg reg1;
VHDL: signal reg1: std_logic;
      attribute dummy: boolean;
      attribute dummy of reg1: signal is true;
```

  `.qsf` Assignment:

```
set_instance_assignment -name PRESERVE_FANOUT_FREE_NODE ON \
    -to <hierarchical path to reg1>
```

- To preserve constant-driven registers while allowing retiming on bits that have drivers, use the `preserve_syn_only` attribute:

```
Verilog: (* preserve_syn_only *) reg reg1;
VHDL: signal reg1: std_logic;
      attribute preserve_syn_only : boolean;
      attribute preserve_syn_only of reg1: signal is true;
```

The following example shows how to assign attributes in PR base compile using a parameter in System Verilog and in VHDL. The example contains a parameter called `base_compile`, which is set to `true` for the PR base compile only.

```
System Verilog:
localparam ON_OFF_STRING = base_compile ? "ON": "OFF";
(* altera_attribute = {"-name PRESERVE_FANOUT_FREE_NODE ", ON_OFF_STRING} *)
logic [WIDTH-1:0] pr_input_register;
(* altera_attribute = {"-name PRESERVE_REGISTER_SYN_ONLY ", ON_OFF_STRING} *)
logic [WIDTH-1:0] pr_output_regsiter;

VHDL:
attribute altera_attribute : string;
type attributeStr_type is array(boolean) of string(1 to 35);
constant attributeStr : attributeStr_type := (true => "-name
PRESERVE_FANOUT_FREE_NODE ON \
     ", false => "-name PRESERVE_FANOUT_FREE_NODE OFF");
attribute altera_attribute of  <PR input registers> : signal is
attributeStr(base_compile);
attribute preserve_syn_only : boolean;
attribute preserve_syn_only of  <PR output registers> : signal is base_compile;
```

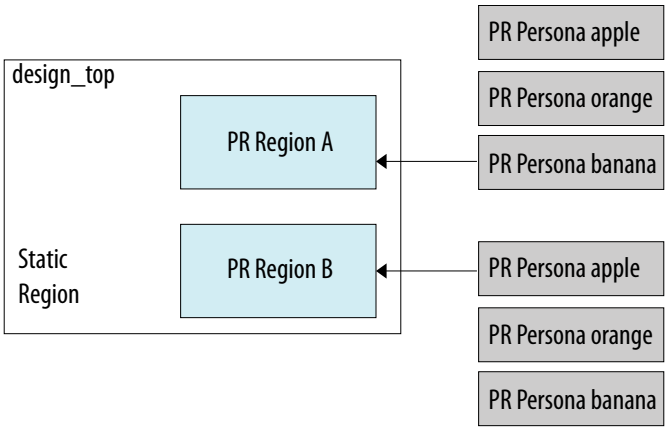
1.7.3. PR File Management

You can simplify the management of PR personas and their corresponding source files by observing one of the following PR project file management methods.

To illustrate these methods, consider a design that includes two PR regions, each with the possible apple, orange, and banana personas.

Figure 26. Example Design with Two PR Regions and Three Personas



- Method 1 (Preferred): Specify Unique Entity and File Names for Each Persona on page 39
- Method 2: Set QSF Assignment for a Parameterized PR Persona on page 40

1.7.3.1. Method 1 (Preferred): Specify Unique Entity and File Names for Each Persona

In PR file management method 1, you specify unique entity and file name pairs for each persona in the project. For example:

- Define the apple persona in the `apple.sv` file
- Define the orange persona in the `orange.sv` file
- Define the banana persona in the `banana.sv` file

Note: For successful compilation and PR operation, all personas must have the exact same port names and widths defined in each `.sv` file.

In the base PR revision RTL, you specify "apple" as the PR persona for both PR regions:

Figure 27. Setting the Base PR Persona to "apple"

```
module design_top ();

    apple u_fruit_0 ( );

    apple u_fruit_1 ( );

endmodule
```

When you set the base persona to [`apple`, `apple`] by setting `u_fruit_0` and `u_fruit_1` as the PR partition and regions, you can easily change the persona occupying the PR region using the **Entity Rebinding** (`ENTITY_REBINDING`) option in the Design Partitions Window, or by editing the `.qsf` directly, as the following examples show:

To specify the orange persona for a PR implementation (impl) revision:

```
set_instance_assignment -name ENTITY_REBINDING orange -to u_fruit_0
set_instance_assignment -name ENTITY_REBINDING orange -to u_fruit_1
```

To specify the banana persona for another PR implementation (impl) revision:

```
set_instance_assignment -name ENTITY_REBINDING banana -to u_fruit_0
set_instance_assignment -name ENTITY_REBINDING banana -to u_fruit_1
```

To specify different personas for each PR region in an implementation revision:

```
set_instance_assignment -name ENTITY_REBINDING orange -to u_fruit_0
set_instance_assignment -name ENTITY_REBINDING banana -to u_fruit_1
```

For each implementation revision, you must ensure that you include the corresponding source file in the project (**Project ➤ Add/Remove Files in Project**).

1.7.3.2. Method 2: Set QSF Assignment for a Parameterized PR Persona

In PR file management method 2, you specify an assignment in the `.qsf` file that sets a parameter or generic to a targeted PR region. The following apply to this method:

- The parameter change applies to the top-level instance of a PR partition.
- Supports application to multiple PR partitions.
- Supports both VHDL and Verilog HDL.

For example, consider the design that Method 1 (Preferred): Specify Unique Entity and File Names for Each Persona on page 39 describes, with two PR regions, each with three possible personas for each PR region.

In the following example, `u_fruit_0` and `u_fruit_1` are set as the PR partitions and regions in the base compile. The FRUIT_TYPE parameter of `0` generates the `apple` entity for the PR personas.

Figure 28. Setting the PR Partitions and Regions in the Base Compile

```
//design_top.sv
module design_top ();

   fruit u_fruit_0 ( );

   fruit u_fruit_1 ( );

endmodule
```

```
module fruit
   #(parameter FRUIT_TYPE=0)
   (  );

   generate if (FRUIT_TYPE==0) begin: gen_apple
       apple appl_inst ( );
   end
   endgenerate

   generate if (FRUIT_TYPE==1) begin: gen_orange
       orange orange_inst ( );
   end
   endgenerate

   generate if (FRUIT_TYPE==2) begin: gen_banana
       banana banana_inst ( );
   end
   endgenerate
endmodule
```

You can then change the parameter values to change the personas.

For example, to set `orange` as the persona for both PR regions, specify the following in the PR implementation revision's `.qsf` file:

1. Add the following lines to set the FRUIT_TYPE parameter to `1`:

```
set_instance_assignment -name RTL_PARAMETER "FRUIT_TYPE=1" -to u_fruit_0
set_instance_assignment -name RTL_PARAMETER "FRUIT_TYPE=1" -to u_fruit_1
```

2. Specify the entity rebinding assignment to associate the fruit entity with instances of `u_fruit_0` and `u_fruit_1`:

```
set_instance_assignment -name ENTITY_REBINDING fruit -to u_fruit_0
set_instance_assignment -name ENTITY_REBINDING fruit -to u_fruit_1
```

The following additional example sets `orange` as the persona for the first PR region, and `banana` as the persona for the second PR region. Similarly, specify the following in the PR implementation revision's `.qsf` file:

1. Add the following lines to set the FRUIT_TYPE parameter to 1 for the first PR region, `u_fruit_0` and 2 for the second PR region, `u_fruit_1`:

```
set_instance_assignment -name RTL_PARAMETER "FRUIT_TYPE=1" -to u_fruit_0
set_instance_assignment -name RTL_PARAMETER "FRUIT_TYPE=2" -to u_fruit_1
```

2. Specify the entity rebinding assignment to associate the fruit entity with instances of `u_fruit_0` and `u_fruit_1`:

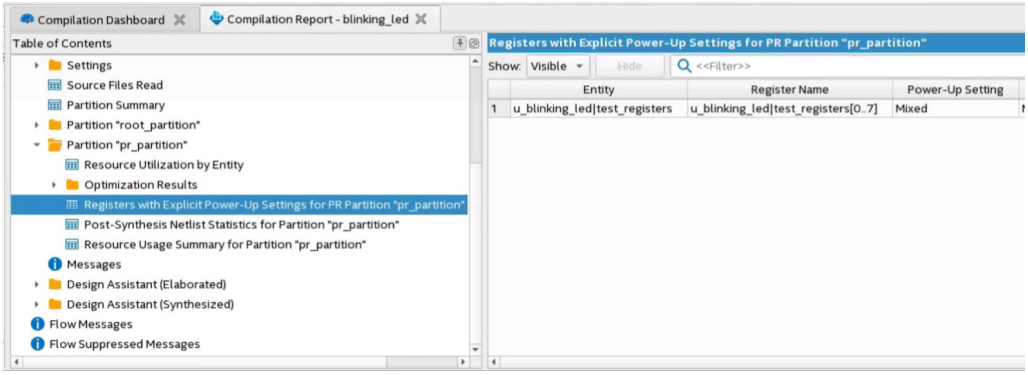
```
set_instance_assignment -name ENTITY_REBINDING fruit -to u_fruit_0
set_instance_assignment -name ENTITY_REBINDING fruit -to u_fruit_1
```

1.7.4. Evaluating PR Region Initial Conditions

Unintended initial conditions in a PR region can lead to errors during partial reconfiguration. Your design may include unintended initial conditions, especially if you port a design not originally intended for partial reconfiguration. The Quartus Prime Pro Edition software reports any initial conditions in the PR partitions for your evaluation following synthesis.

After compiling the base revision that defines the partition, you can view the Registers with Explicit Power-Up Settings report for the partition to identify, locate, and correct any unintended initial conditions. For a specific PR partition, you can view the power-up initial values after synthesizing the base revision in the Synthesis report. The Synthesis report includes power-up initial values in the Partition Statistics section.

Figure 29. Partition Statistics in Synthesis Report



The Messages window also generates a warning or error message about any initial conditions during synthesis processing. After evaluating the initial condition, you can determine whether the condition is correct for design functionality, or change the design to remove dependence on an initial condition that is incompatible with partial reconfiguration.

1.7.5. Creating Wrapper Logic for PR Regions

If all personas for your design do not have identical top-level interfaces, you must create the wrapper logic to ensure that all the personas appear similar to the static region. Define a wrapper for each persona, and instantiate the persona logic within the

wrapper. If all personas have identical top-level interfaces, the personas do not require wrapper logic. In this wrapper, you can create dummy ports to ensure that all the personas of a PR region have the same connection to the static region.

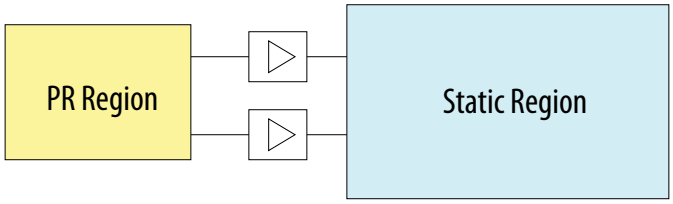
During the PR compilation, the Compiler converts each of the non-global ports on interfaces of the PR region into boundary port wire LUTS. The naming convention for boundary port wire LUTs are `<input_port>~IPORT` for input ports, and `<output_port>~OPORT` for output ports. For example, the instance name of the wire LUT for an input port with the name `my_input`, on a PR region with the name `my_region`, is `my_region|my_input~IPORT`.

1. Manually floorplan the boundary ports using Logic Lock region assignments, or place the boundary ports automatically using the Fitter. The Fitter places the boundary ports during the base revision compile. The boundary LUTs are invariant locations the Fitter derives from the persona you compile. These LUTs represent the boundaries between the static region and the PR routing and logic. The placement remains stationary regardless of the underlying persona, because the routing from the static logic does not vary with a different persona implementation.
2. To constrain all boundary ports within a given region, use a wildcard assignment. For example:

```
set_instance_assignment -name PLACE_REGION "65 59 65 85" -to \
     u_my_top|design_inst|pr_inst|pr_inputs.data_in*~IPORT
```

   This assignment constrains all the wire LUTS corresponding to the IPORTS that you specify within the place region, between the coordinates (65 59) and (65 85).

Figure 30. Wire-LUTs at the PR Region Boundary



Optionally, floorplan the boundary ports down to the LAB level, or individual LUT level. To floorplan to the LAB level, create a 1x1 Logic Lock `PLACE_REGION` constraint (single LAB tall and a single LAB wide). Optionally, specify a range constraint by creating a Logic Lock placement region that spans the range. For more information about floorplan assignments, refer to *Floorplan the Partial Reconfiguration Design*.

Related Information

Step 3: Floorplan the Design on page 14
For more information on floorplanning your design.

1.7.6. Creating Freeze Logic for PR Regions

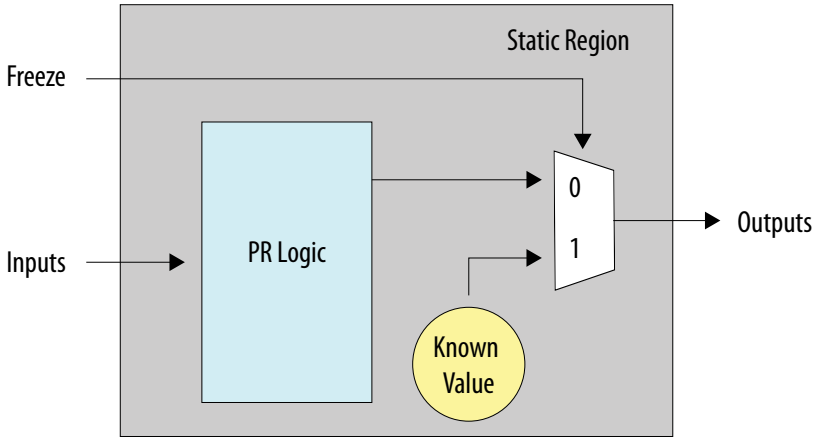
When partially reconfiguring a design, freeze all the outputs of each PR region to a known constant value. This freezing prevents the signal receivers in the static region from receiving undefined signals during the partial reconfiguration process.

The PR region cannot drive valid data until the partial reconfiguration process is complete, and the PR region is reset. Freezing is important for control signals that you drive from the PR region.

The freeze technique that you choose is optional, depending on the particular characteristics of your design. The freeze logic must reside in the static region of your design. A common freeze technique is to instantiate 2-to-1 multiplexers on each output of the PR region, to hold the output constant during partial reconfiguration.

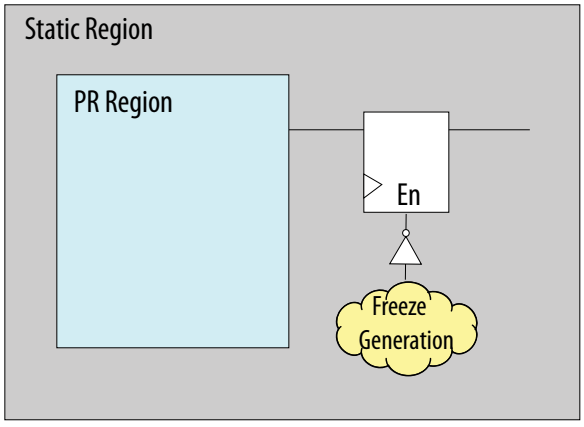
Note: There is no requirement to freeze the global and non-global inputs of a PR region.

Figure 31. Freeze Technique #1



An alternative freeze technique is to register all outputs of the PR region in the static region. Then, use an enable signal to hold the output of these registers constant during partial reconfiguration.

Figure 32. Freeze Technique #2



The Partial Reconfiguration Region Controller IP core includes a freeze port for the region that it controls. Include this IP component with your system-level control logic to freeze the PR region output. For designs with multiple PR regions, instantiate one PR Region Controller IP core for each PR region in the design. The Quartus Prime

software includes the Avalon Memory-Mapped Freeze Bridge and Avalon Streaming Freeze Bridge Intel FPGA IP cores. You can use these IP cores to implement freeze logic, or design your own freeze logic for these standard interface types.

The static region logic must be independent of all the outputs from the PR regions for a continuous operation. Control the outputs of the PR regions by adding the appropriate freeze logic for your design.

1.7.7. Resetting the PR Region Registers

Upon partial reconfiguration of a PR region, the status of the PR region registers become indeterminate. Bring the registers in the PR region to a known state by applying a reset sequence for the PR region. This reset ensures that the system behaves to your specifications. Simply reset the control path of the PR region, if the datapath eventually flushes out within a finite number of cycles. Use active-high local reset instead of active-low, wherever applicable. This technique allows you to automatically hold the PR region in reset, by virtue of the boundary port wire LUT.

Table 7. Supported PR Reset Implementation Guideline

PR Reset Type	Active-High Synchronous Reset	Active-High Asynchronous Reset	Active-Low Synchronous Reset	Active-Low Asynchronous Reset
On local signal	Yes	Yes	Yes	Yes
On global signal	• No (Arria 10) • No (Cyclone 10 GX) • Yes (Stratix 10) • Yes (Agilex 7) • Yes (Agilex 5)	Yes	• No (Arria 10) • No (Cyclone 10 GX) • Yes (Stratix 10) • Yes (Agilex 7) • Yes (Agilex 5)	Yes

1.7.8. Promoting Global Signals in a PR Region

In non-PR designs, the Quartus Prime software automatically promotes high fan-out signals onto dedicated global networks. The global promotion occurs in the Plan stage of design compilation.

In PR designs, the Compiler disables global promotion for signals originating within the logic of a PR region. Instantiate the clock control blocks only in the static region, because the clock floorplan and the clock buffers must be a part of the static region of the design. Manually instantiating a clock control block in a PR region, or assigning a signal in a PR region with the `GLOBAL_SIGNAL` assignment, results in compilation error. To drive a signal originating from the PR region onto a global network:

1. Expose the signal from the PR region.
2. Drive the signal onto the global network from the static region.
3. Drive the signal back into the PR region.

You can drive a maximum of 33 clocks (for Arria 10 and Cyclone 10 GX devices), or 32 clocks (for Agilex 7, Agilex 5, and Stratix 10 devices) into any PR region. You cannot share a row clock between two PR regions.

The Compiler allows only certain signals to be global inside a PR region. Use only global signals to route secondary signals into a PR region, as the following table describes:

Table 8. Supported Signal Types for Driving Clock Networks in a PR Region

Block Type	Supported Global Network Signals
LAB, MLAB	Clock, ACLR, SCLR[4]
RAM, ROM (M20K)	Clock, ACLR, Write Enable (WE), Read Enable (RE), SCLR
DSP	Clock, ACLR, SCLR

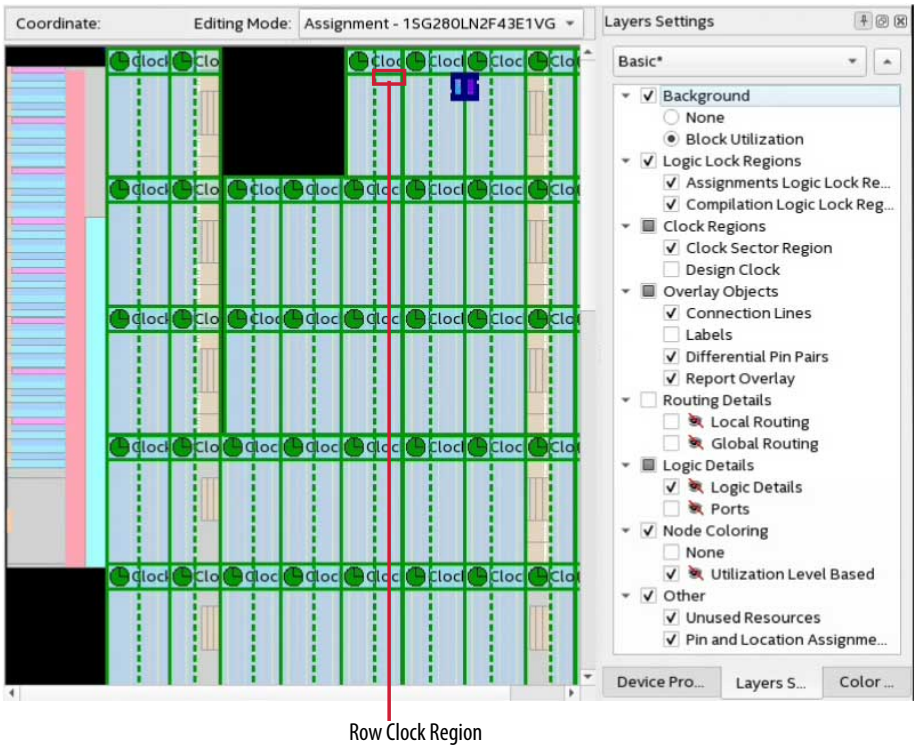
1.7.8.1. Viewing Row Clock Region Boundaries

You can use the Chip Planner to visualize the row clock region boundaries, and to ensure that no two PR regions share a row clock region.

1. Right-click a PR partition name in the Design Partitions Window and click **Locate Node ➤ Locate in Chip Planner**.

Figure 33. Row Clock Region Boundaries in Chip Planner

The green borders in the following floorplan figure indicate clock sectors. A row clock region is one half of a clock sector wide, and one LAB row tall, as indicated by the red box.



2. In Chip Planner, click the **Layers** tab and select the **Basic** layer. The Chip Planner overlays the row clock region boundaries. Adjust the **Basic** layer settings to display specific items.

(4) Only Agilex 7, Agilex 5, and Stratix 10 designs support global SCLR.

1.7.9. Planning Clocks and other Global Routing

There are special PR considerations for the planning for clocks and other global routing. For Agilex 7, Agilex 5, and Stratix 10 designs, you can use the low skew networks (globals) for clocks or resets.

During the base revision compile, you must route any global signal that any PR persona requires into a destination in the PR region. For clock signals, this destination is a register or other synchronous element and the signal entering the clock input. For a reset, the destination should be fed into the appropriate input.

This requirement occurs because PR only reconfigures the last part of the low skew network. If you do not route the root and middle sections of the network during the base compile, you cannot use that revision for the PR.

Consider an example with a super-set of signals for a PR region that consists of:

- Three clocks—`clk_1`, `clk_2`, and `clk_3`.
- Two resets—`rst_1` and `rst_2`.
- Base PR persona—uses `clk_1`, `clk_2`, and `rst_1` only.
- Other personas—use `clk_3` and `rst_2` only.

In this example, the base persona must have a proper destination for the "unused" `clk_3` and `rst_2`. You can accomplish this by driving a single register with a (`*no prune*`) directive inside the base PR persona, with `clk_3` and reset using `rst_2`.

Omitting these destinations results in an error during compilation of the PR implementation second persona.

1.7.10. Implementing Clock Enable for On-Chip Memories

Follow these guidelines to implement clock enable for on-chip memories:

1. To avoid spurious writes during PR programming for memories, implement the clock enable circuit in the same PR region as the M20K or MLAB RAM. This circuit depends on an active-high clear signal from the static region.
2. Before you begin the PR programming, assert this signal to disable the memory's clock enable. Your system PR controller must deassert the clear signal on PR programming completion. You can use the freeze signal for this purpose.
3. Use the Quartus Prime IP Catalog or Platform Designer to instantiate the On-Chip Memory and RAM Intel FPGA IP cores that include an option to automatically add this circuitry.

   Note: If you turn on the **Implement clock-enable circuitry for use in a partial reconfiguration region** option when parameterizing RAM Intel FPGA IP from the IP catalog, the Quartus Prime software adds a `freeze` port to the RAM IP for use in the PR region.

Figure 34. Clock-Enable Circuitry Option in RAM 1 Port Intel FPGA IP Parameter Editor

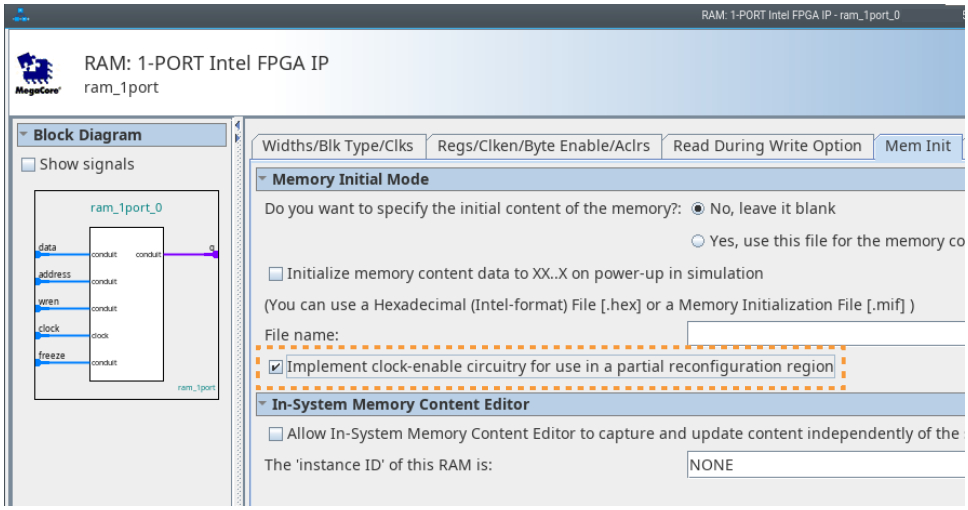


Figure 35. RAM Clock Enable Circuit for PR Region

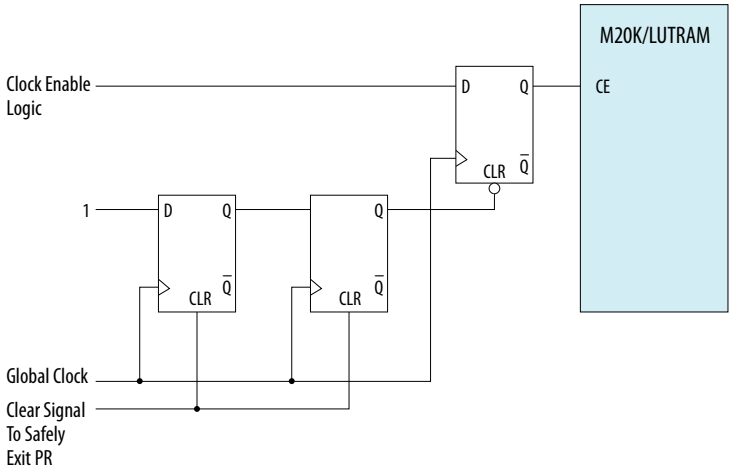

Example 1. Verilog RTL for Clock Enable

```
module mem_enable_verilog (
        input clock,
        input freeze,
        input clken_in,
        output wire ram_wrclocken
);
   reg ce_reg;
    reg [1:0] ce_delay;

    always @(posedge clock, posedge freeze) begin
        if (freeze) begin
            ce_delay <= 2'b0;
        end
        else begin
            ce_delay <= {ce_delay[0], 1'b1};
        end
    end

    always @(posedge clock, negedge ce_delay[1]) begin
```

```
        if (~ce_delay[1]) begin
            ce_reg <= 1'b0;
        end
        else begin
            ce_reg <= clken_in;
        end
    end

    assign ram_wrclocken = ce_reg;
endmodule
```

Example 2. VHDL RTL for Clock Enable

```
ENTITY mem_enable_vhd IS PORT(
        clock      : in  std_logic;
        freeze  : in  std_logic;
        clken_in : in std_logic;
        ram_wrclocken : out std_logic);
END mem_enable_vhd;

ARCHITECTURE behave OF mem_enable_vhd is
    SIGNAL ce_reg: std_logic;
    SIGNAL ce_delay: std_logic_vector(1 downto 0);
BEGIN
PROCESS (clock, freeze)
BEGIN
    IF ((clock'EVENT AND clock = '1') or (freeze'EVENT AND freeze = '1')) THEN
        IF (freeze = '1') THEN
            ce_delay <= "00";
        ELSE
            ce_delay <= ce_delay(0) & '1';
        END IF;
    END IF;

END PROCESS;

PROCESS (clock, ce_delay(1))
BEGIN
    IF ((clock'EVENT AND clock = '1') or (ce_delay(1)'EVENT AND ce_delay(1) =
'0')) THEN
        IF (ce_delay(1) = '0') THEN
            ce_reg <= '0';
        ELSE
            ce_reg <= clken_in;
        END IF;
    END IF;

END PROCESS;

ram_wrclocken <= ce_reg;

END ARCHITECTURE behave;
```

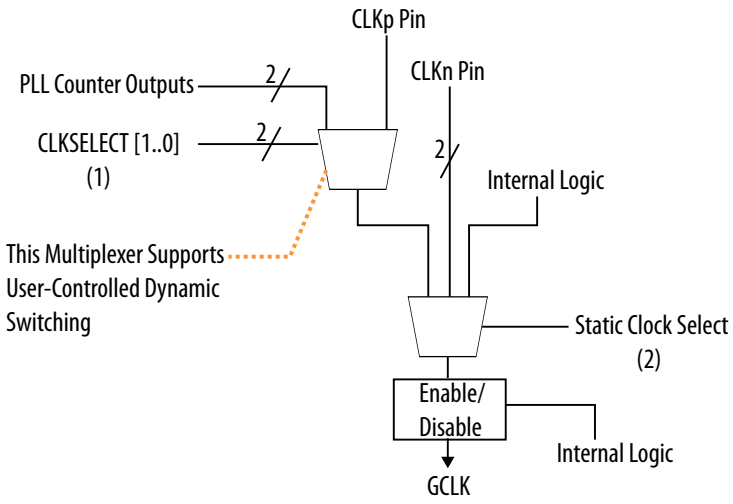
1.7.10.1. Clock Gating

An alternate method to avoid spurious writes of initialized content memories is to implement clock gating circuitry in the PR static region, and feed the clock gating circuitry to the PR region in which the initialized memories are implemented.

Figure 36. Global Clock Control Block



Implement the gating circuitry in the static region, and feed it to the PR region in which the initialized memories are being implemented. Clock gating is logically equivalent to using clock enable on the memories. This method provides the following benefits:

- Uses the enable port of the global clock buffers to disable the clock before starting the partial reconfiguration operation. Also enables the clock on PR completion.
- Ensures that the clock does not switch during reconfiguration, and requires no additional logic to avoid spurious writes.

Clock Control Block (ALTCLKCTRL) Intel FPGA IP User Guide

1.8. Hierarchical Partial Reconfiguration

Hierarchical partial reconfiguration (HPR) is an extension of partial reconfiguration (PR), where you contain one PR region within another PR region. You can create multiple personas for both the child and parent partitions. You nest the child partitions within their parent partitions. Reconfiguring a parent partition does not impact the operation in the static region, but replaces the child partitions of the parent region with default child partition personas.

The HPR design flow includes the following steps:

1. Create a base revision for the design and export the static region, as Step 7: Compile the Base Revision and Export the Static Region on page 21 describes.
2. Create the implementation revision for each persona, as Step 8: Setup PR Implementation Revisions on page 25 describes, and export the parent partitions.
3. Specify the `.qdb` file partition for the static and parent regions.
4. Specify the corresponding entity for the parent or child.

When compiling the implementation revision for an HPR design, you must fully floorplan the child partition, similar to planning the PR region of a base revision. Refer to Using Parent QDB Files from Different Compiles on page 50.

Note: Hierarchical PR (HPR) designs do not support PR bitstream security verification.

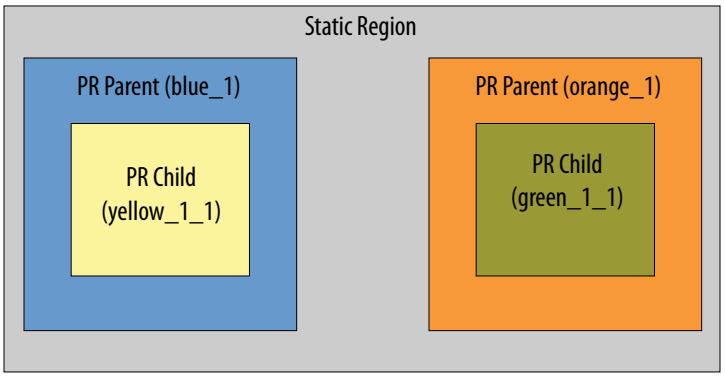
Related Information

AN826: Hierarchical Partial Reconfiguration Tutorial for Intel Stratix 10 GX FPGA Development Board
for step-by-step HPR instructions

1.8.1. Using Parent QDB Files from Different Compiles

For HPR designs, you can use the parent `.qdb` file from the same or different implementation compiles. The following examples illustrate two possible HPR compilation flows, with respect to the following design example block diagram:

Figure 37. Example HPR Design with Parent QDB Files from Different Compiles



Example HPR Design with Parent QDB Files from Different Compiles shows an HPR design hierarchy with the following characteristics:

- The blue and orange regions represent the HPR parent regions.
- The yellow and green boxes represent the child PR regions.
- The blue HPR parent has two personas, blue_1 and blue_2.
- For the yellow child region, the default persona that is compiled with parent blue_1 is yellow_1_1.
- The second child persona that can be compiled by blue_1 is yellow_2_1.
- The orange HPR parent has the same characteristics as the blue HPR parent.

Considering these HPR design characteristics, the following describes one possible HPR compilation flow:

HPR Compilation Flow A:

1. Blue_1, yellow_1_1, orange_1, green_1_1.
2. `Blue_1.qdb`, yellow_1_2, `orange_1.qdb`, green_1_2
3. Blue_2, yellow_2_1, orange_2, green_2_1
4. `Blue_2.qdb`, yellow_2_2, `orange_2.qdb`, green_2_2

In Flow A, in steps 2 and 4, the parent region `.qdb` files come from the same implementation compile. Step 2 uses `blue_1.qdb` and `orange_1.qdb` that step 1 generates in the same implementation compile.

HPR also supports import of the parent and child PR partitions from different implementation compiles:

HPR Compilation Flow B:

1. Blue_1, yellow_1_1, orange_1, green_1_1.
2. Blue_2, yellow_2_1, orange_2, green_2_1
3. `Blue_1.qdb`, yellow_1_2, `orange_2.qdb`, green_2_2
4. `Blue_2.qdb`, yellow_2_2, `orange_1.qdb`, green_1_2

In Flow B, `blue_1.qdb` and `orange_2.qdb` come from two different implementation compiles. Step 1 generates `blue_1.qdb`. Step 2 implementation compile generates `orange_2.qdb`.

1.9. Partial Reconfiguration Design Timing Analysis

The interface between partial and static partitions remains the same for each PR implementation revision. Perform timing analysis on each PR implementation revision to ensure that there are no timing violations. To ensure timing closure of a design with multiple PR regions, you can create aggregate revisions for all possible PR region combinations for timing analysis.

Note: Logic Lock regions impose placement constraints that affect the performance and resource utilization of your PR design. Ensure that the design has additional timing allowance and available device resources. Selecting the largest and most timing-critical persona as your base persona optimizes the timing closure. In addition, if you compile the base design with time borrowing enabled, compile the implementation designs with time borrowing enabled. Otherwise, time borrowing amounts in the base design are reset to zero, and the design may not pass timing. If this condition occurs, you can use the `update_timing_netlist –recompute_borrow` command to restore time borrowing amounts throughout the design for timing analysis.

Related Information

Quartus Prime Pro Edition User Guide: Timing Analyzer

1.9.1. Running Timing Analysis on Aggregate Revisions

To ensure timing closure of a design with multiple PR regions, you create aggregate revisions for all possible PR region combinations and run timing analysis.

1. To open the **Revisions** dialog box, click **Project ➤ Revisions**.
2. To create a new revision, double-click **<<new revision>>**.
3. Specify the **Revision name** and select the base revision for **Based on Revision**.
4. To export the post-fit database from the base compile (static partition), type the following command in the Quartus Prime shell:

```
quartus_cdb <project name> <base revision> --export_block \
     "root_partition" --snapshot final --file \
     "<base revision name>.qdb"
```

Note: Ensure that you include all the `.sdc` and `.ip` files for the static and PR regions. To detect the clocks, ensure that the `.sdc` file for the PR Controller IP follows the entry of any `.sdc` file that creates the clocks that the IP core uses. You facilitate this order by ensuring the `.ip` file for the PR Controller IP comes after any `.ip` or `.sdc` files that you use to create these clocks in the `.qsf` file for the project revision. Refer to Partial Reconfiguration Solutions IP User Guide on page 74 for more information.

5. To export the post-fit database from multiple personas (for the PR implementation revisions), type the following commands in the Quartus Prime shell:

```
quartus_cdb <project name> -c <PR1 revision> --export_block \
     <PR1 Partition name> --snapshot final --file "pr1.qdb"
quartus_cdb <project name> -c <PR2 revision> --export_block \
     <PR2 Partition name> --snapshot final --file "pr2.qdb"
```

6. To import the post-fit databases of the static region as an aggregate revision, type the following commands in the Quartus Prime shell:

```
quartus_cdb <project name> -c <aggr_rev> --import_block \
     "root_partition" --file "<base revision name>.qdb"
quartus_cdb <project name> -c <aggr_rev> --import_block \
     <PR1 partition name> --file "pr1.qdb"
quartus_cdb <project name> -c <aggr_rev> --import_block \
     <PR2 Partition name> --file "pr2.qdb"
```

7. To integrate post-fit database of all the partitions, type the following command in the Quartus Prime shell:

```
quartus_fit <project name> -c <aggr_rev>
```

Note: The Fitter verifies the legality of the post-fit database, and combines the netlist for timing analysis. The Fitter does not reroute the design.

8. To perform timing analysis on the aggregate revision, type the following command in the Quartus Prime shell:

```
quartus_sta <proj name> -c <aggr_rev>
```

9. Run timing analysis on aggregate revision for all possible PR persona combinations. If a specific persona fails timing closure, recompile the persona and perform timing analysis again.

1.10. Partial Reconfiguration Design Simulation

Simulation verifies the behavior of your design before device programming. The Quartus Prime Pro Edition software supports simulating the delivery of a partial reconfiguration bitstream to the PR region. This simulation allows you to observe the resulting change and the intermediate effect in a reconfigurable partition.

The Quartus Prime Pro Edition software supports simulation of PR persona transitions through the use of simulation multiplexers. You use the simulation multiplexers to change which persona drives logic inside the PR region during simulation. This simulation allows you to observe the resulting change and the intermediate effect in a reconfigurable partition.

Similar to non-PR design simulations, preparing for a PR simulation involves setting up your simulator working environment, compiling simulation model libraries, and running your simulation.

The Quartus Prime software provides simulation components to help simulate a PR design, and can generate the gate-level PR simulation models for each persona. Use either the behavioral RTL or the gate-level PR simulation model for simulation of the PR personas. The gate-level PR simulation model allows for accurate simulation of registers in your design and reset sequence verification. These technology-mapped registers do not assume initial conditions.

You can use the PR mode of the EDA netlist writer to generate the gate level netlist of a PR region. Refer to the "EDA Netlist Writer and Gate Level-Netlists" section of the *Quartus Prime Pro Edition User Guide: Third Party Simulation*.

- Quartus Prime Pro Edition User Guide: Third Party Simulation

1.10.1. Partial Reconfiguration Simulation Flow

At a high-level, a PR operation consists of the following steps:

1. System-level preparation for a PR event.
2. Retrieval of the partial bitstream from memory.
3. Transmission of the partial bitstream to the PR control block or SDM.
4. Resulting change in the design as a new persona becomes active.
5. Post-PR system coordination.
6. Use of the new persona in the system.

You can simulate each of these process steps in isolation, or as a larger sequence depending on your verification type requirement.

- Generating the PR Persona Simulation Model on page 140
- Secure Device Manager Partial Reconfiguration Simulation Model on page 143

1.10.2. Simulating PR Persona Replacement

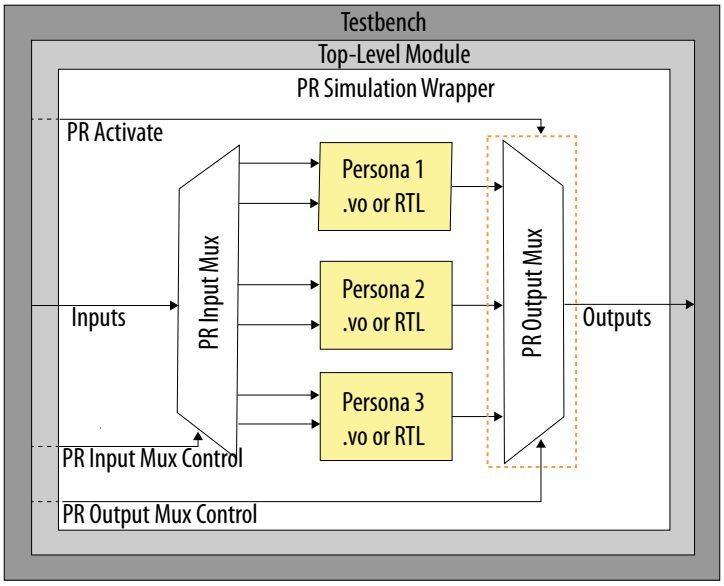
The logical operation of the PR partition changes when a new persona loads during the partial reconfiguration process. Simulate the replacement of personas using multiplexers on the input and output of the persona under simulation.

Create RTL wrapper logic to represent the top-level of the persona. The wrapper instantiates the default persona during compilation. During simulation, the wrapper allows the replacement of the active persona with another persona. Instantiate each persona as the behavioral RTL in the PR simulation model the Quartus Prime EDA Netlist Writer generates.

The Quartus Prime software includes simulation modules to interface with your simulation testbench:

- `altera_pr_wrapper_mux_in`
- `altera_pr_wrapper_mux_out`
- `altera_pr_persona_if` (SystemVerilog interface allows you to connect the wrapper multiplexers to a testbench driver)

Figure 38. Simulation of PR Persona Switching



Example 3. RTL Wrapper for PR Persona Switching Simulation

The `pr_activate` input of the `altera_pr_wrapper_mux_out` module enables the MUX to output X. This functionality allows the simulation of unknown outputs from the PR persona, and also verifies the normal operation of the design's freeze logic. The following code corresponds to the simulation of PR persona switching, shown in the above figure:

```
module pr_core_wrapper
(
   input wire a,
   input wire b,
   output wire o
);

localparam ENABLE_PERSONA_1 = 1;
localparam ENABLE_PERSONA_2 = 1;
localparam ENABLE_PERSONA_3 = 1;
localparam NUM_PERSONA = 3;

logic pr_activate;
int persona_select;

altera_pr_persona_if persona_bfm();
assign pr_activate = persona_bfm.pr_activate;
assign persona_select = persona_bfm.persona_select;

wire a_mux [NUM_PERSONA-1:0];
```

```
wire b_mux [NUM_PERSONA-1:0];
wire o_mux [NUM_PERSONA-1:0];

generate
   if (ENABLE_PERSONA_1) begin
      localparam persona_id = 0;

      `ifdef ALTERA_ENABLE_PR_MODEL
         assign u_persona_0.altera_sim_pr_activate = pr_activate;
      `endif

      pr_and u_persona_0
      (
         .a(a_mux[persona_id]),
         .b(b_mux[persona_id]),
         .o(o_mux[persona_id])
      );
   end
endgenerate

generate
   if (ENABLE_PERSONA_2) begin
      localparam persona_id = 1;

      `ifdef ALTERA_ENABLE_PR_MODEL
         assign u_persona_1.altera_sim_pr_activate = pr_activate;
      `endif

      pr_or u_persona_1
      (
         .a(a_mux[persona_id]),
         .b(b_mux[persona_id]),
         .o(o_mux[persona_id])
      );

   end
endgenerate

generate
   if (ENABLE_PERSONA_3) begin
      localparam persona_id = 2;

      `ifdef ALTERA ENABLE PR MODEL
         assign u_persona_2.altera_sim_pr_activate = pr_activate;
      `endif

      pr_empty u_persona_2
      (
         .a(a_mux[persona_id]),
         .b(b_mux[persona_id]),
         .o(o_mux[persona_id])
      );

   end
endgenerate

altera_pr_wrapper_mux_in #(.NUM_PERSONA(NUM_PERSONA), .WIDTH(1)) \
     u_a_mux(.sel(persona_select), .mux_in(a), .mux_out(a_mux));

altera_pr_wrapper_mux_in #(.NUM_PERSONA(NUM_PERSONA), .WIDTH(1)) \
     u_b_mux(.sel(persona_select), .mux_in(b), .mux_out(b_mux));

altera_pr_wrapper_mux_out #(.NUM_PERSONA(NUM_PERSONA), .WIDTH(1)) \
     u_o_mux(.sel(persona_select), .mux_in(o_mux), .mux_out(o), .pr_activate \
     (pr_activate));

endmodule
```

1.10.2.1. altera_pr_persona_if Module

Instantiate the altera_pr_persona_if SystemVerilog interface in a PR region simulation wrapper to connect to all the wrapper multiplexers. Optionally, connect pr_activate to the PR simulation model.

Connect the interface's persona_select to the sel port of all input and output multiplexers. Connect the pr_activate to the pr_activate of all the output multiplexers. Optionally, connect the report events to the report event ports of the PR simulation model. Then, the PR region driver testbench component can drive the interface.

```
interface altera_pr_persona_if;
   logic pr_activate;
   int   persona_select;

   event report_storage_if_x_event;
   event report_storage_if_1_event;
   event report_storage_if_0_event;
   event report_storage_event;

   initial begin
      pr_activate <= 1'b0;
   end
endinterface : altera_pr_persona_if
```

The <*QUARTUS_INSTALL_DIR*>/eda/sim_lib/altera_lnsim.sv file defines the altera_pr_persona_if component.

1.10.2.2. altera_pr_wrapper_mux_out Module

The altera_pr_wrapper_mux_out module allows you to multiplex the outputs of all PR personas to the outputs of the PR region wrapper.

Instantiate one multiplexer per output port. Specify the active persona using the sel port of the multiplexer. The pr_activate port allows you to drive the multiplexer output to "x", to emulate the unknown value of PR region outputs during a PR operation. Parameterize the component to specify the number of persona inputs, the multiplexer width, and the MUX output value when pr_activate asserts.

```
module altera_pr_wrapper_mux_out #(
   parameter NUM_PERSONA = 1,
   parameter WIDTH = 1,
   parameter [0:0] DISABLED_OUTPUT_VAL = 1'bx
) (
   input int sel,
   input wire [WIDTH-1 : 0] mux_in [NUM_PERSONA-1:0],
   output reg [WIDTH-1:0]   mux_out,
   input wire               pr_activate
);

   always_comb begin
      if ((sel < NUM_PERSONA) && (!pr_activate))
         mux_out = mux_in[sel];
      else
         mux_out = {WIDTH{DISABLED_OUTPUT_VAL}};
   end

endmodule : altera_pr_wrapper_mux_out
```

The <*QUARTUS_INSTALL_DIR*>/eda/sim_lib/altera_lnsim.sv file defines the altera_pr_wrapper_mux_out component.

1.10.2.3. `altera_pr_wrapper_mux_in` Module

The `altera_pr_wrapper_mux_in` module allows you to de-multiplex inputs to a PR partition wrapper for all PR personas.

Instantiate one multiplexer per input port. Specify the active persona using the `sel` port of the multiplexer. Parameterize the component to specify the number of persona outputs, the multiplexer width, and the MUX output for any disabled output. When using the `altera_pr_wrapper_mux_in` to mux a clock input, use the `DISABLED_OUTPUT_VAL` of 0, to ensure there are no simulation clock events of the disabled personas.

```
module altera_pr_wrapper_mux_in#(
   parameter NUM_PERSONA = 1,
   parameter WIDTH = 1,
   parameter [0:0] DISABLED_OUTPUT_VAL = 1'bx
) (

   input int sel,
   input wire [WIDTH-1:0] mux_in,
   output reg [WIDTH-1 : 0] mux_out [NUM_PERSONA-1:0]
);
   always_comb begin
      for (int i = 0; i < NUM_PERSONA; i++)
         if (i == sel)
            mux_out[i] = mux_in;
         else
            mux_out[i] = {WIDTH{DISABLED_OUTPUT_VAL}};
   end

endmodule : altera_pr_wrapper_mux_in
```

The *<QUARTUS_INSTALL_DIR>*`/eda/sim_lib/altera_lnsim.sv` file defines the `altera_pr_wrapper_mux_in` component.

1.11. Partial Reconfiguration Design Debugging

The following Intel FPGA IP cores support system-level debugging in the static region of a PR design:

- In-System Memory Content Editor
- In-System Sources and Probes Editor
- Virtual JTAG
- Nios II JTAG Debug Module
- Signal Tap Logic Analyzer

In addition, the Signal Tap logic analyzer allows you to debug the static or partial reconfiguration (PR) regions of the design. If you only want to debug the static region, you can use the In-System Sources and Probes Editor, In-System Memory Content Editor, or System Console with a JTAG Avalon bridge.

Related Information

- System Debugging Tools Overview
- AN 841: Signal Tap Tutorial for Intel Stratix 10 Partial Reconfiguration Design

1.11.1. Debugging PR Designs with the Signal Tap Logic Analyzer

To use the Signal Tap logic analyzer to debug PR designs, you must create a debug bridge to extend Signal Tap debugging into the PR partition. You can then use Signal Tap to debug by connecting to the debug bridge. To use the debug bridge, you instantiate the SLD JTAG Bridge Agent Intel FPGA IP, SLD JTAG Bridge Host Intel FPGA IP, and Intel Configuration Reset Release Endpoint to Debug Logic IP for each PR region in your design.

You must instantiate the following IP in your design to ensure you can use Signal Tap to debug your PR region:

1. Instantiate the SLD JTAG Bridge Agent IP in the static region.
2. Instantiate the SLD JTAG Bridge Host IP and the Intel Configuration Reset Release Endpoint to Debug Logic IP in the PR region of the default persona.
3. Instantiate the SLD JTAG Bridge Host IP and the Intel Configuration Reset Release Endpoint to Debug Logic IP, for each of the personas, whenever creating revisions for the personas.

The Signal Tap logic analyzer uses the hierarchical debug capabilities provided by the Quartus Prime software to tap signals in the static and PR regions simultaneously.

You can debug multiple personas present in your PR region, as well as multiple PR regions. For complete information on the debug infrastructure using hierarchical hubs, refer to *Quartus Prime Pro Edition User Guide: Debug Tools*.

1.11.2. Instantiating the Intel Configuration Reset Release Endpoint to Debug Logic IP

You must instantiate the Intel Configuration Reset Release Endpoint to Debug Logic IP in each PR region if multiple PR regions are present in the design. This IP ensures proper function by providing a reset signal to debug logic, such as Signal Tap logic, after partial reconfiguration. This reset signal must be high during configuration, and then this reset signal must go low once partial reconfiguration is complete. You must not release this reset signal after releasing the PR logic reset. The time of this reset release affects the Signal Tap power-up trigger feature. The reset signal must stay low until the next reconfiguration.

Note: Do not assert this reset input while the device is in the user operational mode. Asserting this reset input while the device is in the user operational mode results in incorrect operation in Signal Tap and other debugging tools.

If you omit the Intel Configuration Reset Release Endpoint to Debug Logic IP from your PR design, The Compiler issues the following error message:

```
Error(11176): Alt_sld_fab_1.alt_sld_fab_1.alt_sld_fab_1: The Intel Configuration
Reset Release
Endpoint to Debug Logic IP must be instantiated to provide the reset signal to
the debug logic,
such as Signal Tap, etc. after the partial configuration is performed.
```

Refer to the Intel FPGA Knowledge Database and search for Error 11176 for more information.

1.12. Partial Reconfiguration Security (Stratix 10 Designs)

Stratix 10 devices support the following optional PR security features to help confirm that a PR region persona is protected, contains no threats to platform integrity or confidentiality, and cannot access unauthorized areas of the FPGA device before loading a persona into the FPGA.

- PR Bitstream Security Validation—confirms that the persona does not use FPGA resources that are unauthorized by validating a `.pmsf` against a Secure Mask Settings File (`.smsf`), as PR Bitstream Security Validation (Stratix 10 Designs) on page 59 describes.
- PR Bitstream Authentication—ensures that the firmware and PR bitstream are from a trusted source by provisioning the FPGA device with the owner public root key, as PR Bitstream Authentication (Stratix 10 Designs) on page 61 describes.
- PR Bitstream Encryption—protects the bitstream contents by encrypting the static region and all associated bitstreams using the same AES root key, as PR Bitstream Encryption (Stratix 10 Designs) on page 61 describes.

1.12.1. PR Bitstream Security Validation (Stratix 10 Designs)

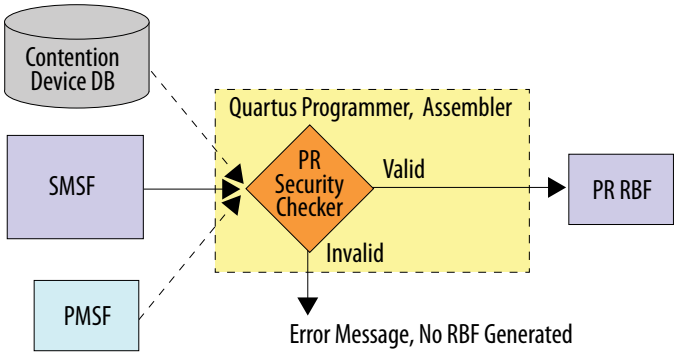
PR bitstream security validation confirms that the persona does not access FPGA resources that are unauthorized by the platform owner.

Note: PR bitstream security validation only supports Stratix 10 devices. Hierarchical PR (HPR) designs do not support PR bitstream security verification.

PR bitstream security validation enables multi-tenant FPGA usage. For example, a platform owner partitions a single device to host multiple third-party clients. The platform owner may not trust the clients, and the clients may not trust each other, but the clients trust the platform owner. PR bitstream security validation provides the platform owner and clients protection from any party corrupting the proprietary server, the client configurations, or from initiating a peek or poke attack by a subsequent partial reconfiguration.

PR bitstream validation allows the platform owner to determine whether the client has modified their `.pmsf` file in an attempt to damage the FPGA, or has attempted connection to signals without access. To be effective, the platform owner must accept only `.pmsf` files (not `.rbf`) from the client, and the platform owner must validate all client `.pmsf` files. Thereafter, the Programmer requires both the `.pmsf` and `.smsf` to generate the PR bitstream (`.rbf`) for this PR region, ensuring that the PR persona can only change bits that the persona owns. The Platform Owner can optionally release `.smsf` files to third-party Clients as part of the PR region collateral.

Figure 39. PR Bitstream Security Validation in Programmer



For PR bitstream validation, the platform owner generates the `.smsf` file themselves, to ensure that the platform owner can trust the `.smsf`. The bitstream validation check compares the client supplied `.pmsf` against the trusted `.smsf`. The comparison fails if the `.pmsf` is invalid for deliberate or accidental reasons.

The Platform Owner should follow these steps to license, enable, and use PR bitstream security validation:

1. Obtain the license file to enable generation of `.smsf` files for PR regions during base compilation, and to perform PR bitstream security validation during PR bitstream generation in the Programmer. To obtain the license, login or register for a My Intel account, and then submit an Intel Premier Support case quoting reference number 22013030316 to request a license key.
2. To add the license file to the Quartus Prime Pro Edition software, click **Tools ➤ License Setup** and specify the feature **License File**.
3. To enable PR security validation features, add the following line to the project `.qsf`:

```
set_global_assignment -name PR_SECURITY_VALIDATION on
```

4. Compile the base revision.
5. Following base compilation, view the Assembler reports to view the generated `.smsf` files required for bitstream generation for each PR region.
6. The Client provides the `.pmsf` to the Platform Owner.
7. The Platform Owner validates the `.pmsf`, converts the `.pmsf` to `.rbf`, and configures the FPGA device with the `.rbf`. The Platform Owner converts the `.pmsf` to a PR bitstream. Provide the `.smsf` file to `quartus_pfg` to instruct the tool to validate the `.pmsf` against that `.smsf`. Then generate a bitstream only if the files are compatible.

```
quartus_pfg -c -o smsf_file=<smsf_file> <pmsf_file> <output_rbf_file>
```

Stratix 10 Device Security User Guide

1.12.2. PR Bitstream Authentication (Stratix 10 Designs)

PR bitstream authentication helps to ensure that the firmware and the PR bitstream are from a trusted source, by provisioning the FPGA device with the owner public root key. Authentication is a basic component of device security and bitstream protection.

In PR bitstream authentication, the signed base bitstream must first be configured to the device. Then, the signed PR bitstream is used to configure one or more partial reconfiguration regions of the FPGA device. The signed PR bitstream must match the configured static region.

The following use cases summarize successful and unsuccessful PR bitstream authentication:

PR Authentication Success Use Case:

- **Partial Reconfiguration with Authenticated PR Bitstream**—in a successful PR authentication use case, the designer performs full chip configuration using an authenticated `.sof` file. The designer can only configure the partially reconfigurable regions of the FPGA that are signed with the design signature private key, and that match the currently configured static region. The PR bitstreams are authenticated to ensure that only authorized users can provide the PR bitstream.

PR Authentication Failure Scenarios

The following are some PR authentication failure scenarios:

- **PR Bitstream Is Unsigned**—when the target FPGA device determines that the PR bitstream is unsigned, then the PR operation halts and PR bitstream security displays a PR error message.
- **PR Bitstream Is Signed with Expired or Invalid Signature**—when the target FPGA device determines that the PR bitstream is signed with an expired or invalid signature, then the PR operation halts and PR bitstream security displays a PR error message.
- **PR Success after PR Failure from Expired or Invalid Signature**—when PR of the target FPGA device fails with an error caused by an expired or invalid signature, you can provide a bitstream signed with a valid key to perform the PR operation successfully.

Related Information

Stratix 10 Device Security User Guide

1.12.3. PR Bitstream Encryption (Stratix 10 Designs)

PR bitstream encryption helps protect the bitstream. You can configure each PR region with multiple PR bitstream files. Any of these files may contain sensitive or valuable data that encryption can protect. PR bitstream encryption allows you to encrypt the static region and all associated bitstreams using the same AES root key.

Note: PR bitstream authentication is a prerequisite of PR bitstream encryption use. You must enable PR bitstream authentication before using PR bitstream encryption.

In PR bitstream encryption, you must first configure the device with the encrypted base bitstream. Next, you configure one or more partial reconfiguration regions with the encrypted PR bitstream. The encrypted PR bitstream must match the configured static region.

You also can configure the signed PR bitstream after the first encrypted base bitstream configuration. For all subsequent partial reconfigurations, both the signed and encrypted PR bitstreams are supported.

PR bitstream encryption requires the following prerequisite conditions:

- The Base and PR designs must share the same authentication key.
- The Base and PR designs must share the same encryption key.
- All PR regions must be encrypted or none. A combination of encrypted and non-encrypted designs is unsupported.
- When you enable authentication, both the base and the PR design must be authenticated. This requirement ensures that only authorized users can provide the full or PR bitstream to the owned FPGA device.
- When you enable authentication or encryption, the Quartus Prime Assembler skips the auto-generation of `.rbf` files for PR designs, and only generates the `.pmsf` file.

Note: For bitstream encryption details, refer to the *Stratix 10 Device Security User Guide*.

Related Information

Stratix 10 Device Security User Guide

1.13. PR Bitstream Compression and Encryption (Arria 10 and Cyclone 10 GX Designs)

You can compress and encrypt the base bitstream and the PR bitstream for your Arria 10 and Cyclone 10 GX PR project using options available in the Quartus Prime software.

Compress the base and PR programming bitstreams independently, based on your design requirements. When encrypting only the base image, specify whether or not to encrypt the PR images. The following guidelines apply to PR bitstream compression and encryption:

- You can encrypt the base and PR image independently. You can use a non-volatile encryption key for the base image, and a volatile encryption key for the PR image.
- Refer to Clock-To-Data Ratio for Bitstream Encryption and Compression to ensure the correct Clock-to-Data (CD) ratio setting for encryption or compression.

Enable enhanced decompression by turning on the **Enable enhanced decompression** option when specifying the parameters in the IP Catalog or Platform Designer parameter editors.

Note: You cannot use enhanced decompression together with encryption simultaneously. Enhanced decompression is only available with the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP.

1.13.1. Generating an Encrypted PR Bitstream (Arria 10 or Cyclone 10 GX Designs)

To partially reconfigure your Arria 10 or Cyclone 10 GX device with an encrypted bitstream:

1. Create a 256-bit key file (`.key`).
2. To generate the key programming file (`.ekp`) from the Quartus Prime shell, type the following command:

```
quartus_cpf --key <keyfile>:<keyid> \
     <base_sof_file> <output_ekp_file>
```

   For example:

```
quartus_cpf --key my_key.key:key1 base.sof key.ekp
```

3. To generate the encrypted PR bitstream (`.rbf`), run the following command:

```
quartus_cpf -c <pr_pmsf_file> <pr_rbf_file>
qcrypt -e --keyfile=<keyfile> --keyname=<keyid> –lockto=\
     <qlk file> --keystore=<battery|OTP> \
     <pr_rbf_file> <pr_encrypted_rbf_file>
```

   - `lockto`—specifies the encryption lock.
   - `keystore`—specifies the volatile key (battery) or the non-volatile key (OTP).

   For example:

```
quartus_cpf -c top_v1.pr_region.pmsf top_v1.pr_region.rbf \
     qcrypt -e --keyfile=my_key.key --keyname=key1 --keystore=battery \
     top_v1.pr_region.rbf top_v1_encrypted.rbf
```

4. To program the key file as volatile key (default) into the device, type the following command:

```
quartus_pgm -m jtag -o P;<output_ekp_file>
```

   For example:

```
quartus_pgm -m jtag -o P;key.ekp
```

5. To program the base image into the device, type the following command:

```
quartus_pgm -m jtag -o P;<base_sof_file>
```

   For example:

```
quartus_pgm -m jtag -o P;base.sof
```

6. To partially reconfigure the device with the encrypted bitstream, type the following command:

```
quartus_pgm -m jtag --pr <output_encrypted_rbf_file>
```

   For example:

```
quartus_pgm -m jtag --pr top_v1_encrypted.rbf
```

Note: `qcrypt` generates an error if the **Enable bitstream compatibility check** parameter is enabled for an instance of the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP. Use one of the following methods to avoid this error:

- Use the **Convert Programming Files** dialog box, rather than `qcrypt`, to generate the encrypted PR bitstream, as *Generating PR Bitstream Files* describes.
- If you want use `qcrypt` with Arria 10 or Cyclone 10 GX designs, regenerate the Partial Reconfiguration Controller IP without the **Enable bitstream compatibility check** option enabled, and with the **Enable hierarchical PR support** option enabled, as *Adding the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP* describes. Recompile the design before regenerating the PR bitstream.

- Adding the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP

1.13.2. Clock-to-Data Ratio for Bitstream Encryption and Compression (Arria 10 or Cyclone 10 GX Designs)

The following table lists the valid combinations of bitstream encryption and compression. The Clock-to-Data (CD) ratio is defined as the number of clock cycles that each cycle of data must remain valid before the next clock cycle. For example, a CD ratio of 4 means that the data must remain valid for 4 clock cycles before the next cycle. Enhanced decompression uses the same CD ratio as plain bitstreams (that is, with both encryption and compression off). When enhanced compression is enabled, always refer to x16 data width. If you use compression and enhanced compression together, the CD ratio follows the compression bitstream - 4. If you use plain and enhanced compression together, the CD ratio follows the plain bitstream - 1.

Table 9. Valid Combinations and CD Ratio for Bitstream Encryption and Compression

Configuration Data Width	AES Encryption	Basic Compression	CD Ratio
x8	Off	Off	1
	Off	On	2
	On	Off	1
x16	Off	Off	1
	Off	On	4
	On	Off	2
x32	Off	Off	1
	Off	On	8
	On	Off	4

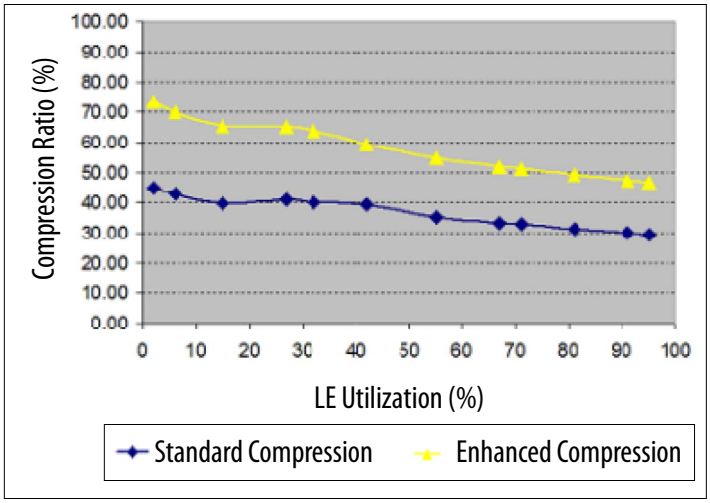
Use the exact CD ratio that the *Valid combinations and CD Ratio for Bitstream Encryption and Compression* table specifies for different bitstream types. The CD ratio for plain `.rbf` must be 1. The CD ratio for compressed `.rbf` must be 2, 4 or 8, depending on the width. Do not specify the CD ratio as the necessary minimum to support different bitstream types.

1.13.3. Data Compression Comparison

Standard compression results in a 30-45% decrease in `.rbf` size. Use of the enhanced data compression algorithm results in 55-75% decrease in `.rbf` size. The algorithm increases the compression at the expense of additional core area required to implement the compression algorithm.

The following figure shows the compression ratio comparison across PR designs with varying degrees of Logic Element (LE):

Figure 40. Compression Ratio Comparison between Standard Compression and Enhanced Compression



1.14. Avoiding PR Programming Errors

You can use the following guidelines to avoid or resolve common PR programming errors.

Table 10. PR Programming Guidelines

PR Programming Guideline	Description
Device in project must match device on board	Confirm the target FPGA device that you specify for the project matches the device on the development kit you target. These two devices must be the same. Click **Assignments ➤ Device** to view the target device.
Programmer versions must match	When using the Quartus Prime Programmer for PR programming, confirm that the Programmer version matches the Quartus Prime version that you use for compilation. A mismatch between the Programmer and Quartus Prime software version can occur if you compile on one machine, and then program on a different machine with a different Quartus Prime version. The software version match is especially critical for Agilex 7, Agilex 5, and Stratix 10 designs because the PR configuration hardware has dependencies inside the Programmer.
Specify a lower JTAG clock frequency	Lower the JTAG clock frequency to 6MHz: 1. In the Programmer window, click **Hardware Setup**, and then select **Intel FPGA Download Cable II** as the programming hardware. 2. For the **Hardware frequency**, specify a value from 24000000 (24MHz) to 6000000 (6MHz).

continued...

PR Programming Guideline	Description
	Close timing for all revisions	Confirm that each project revision closes timing after design compilation: 1. In the Compilation Report, expand the **Timing Analyzer ➤ Slow 900mV 100C Model** folders, and then view the Setup Summary, Hold Summary, Recovery Summary, Removal Summary, and Minimum Pulse Width Summary reports. In each report, verify that there are no timing violations indicated by a negative **Slack** value in the report. 2. Repeat step 1 to verify timing closure in the **Slow 900mV 0C Model**, the **Fast 900mV 100C Model**, and the **Fast 900mV 0C Model**. The design closes timing when there are no negative **Slack** values for any clock in the report.  3. Repeat steps 1 and 2 for each project revision in the PR design.

Note: If an error occurs during PR operation for an Agilex 7, Agilex 5, or Stratix 10 design using SEU detection, the PR region is frozen, becomes non-functional, and SEU detection is disabled for all sectors within the PR region and certain sectors adjacent to PR region. To resolve this error and restore SEU detection on affected areas, perform a full chip configuration.

1.15. Exporting a Version-Compatible Compilation Database for PR Designs

Using version-compatible databases, you can import the base revision of a PR design to a later version of the Quartus Prime software, and then compile the PR revisions in the later version of software, without recompiling the static region.

This technique is helpful when you want to compile and generate bitstreams for the PR implementation revisions with a later version of the Quartus Prime software. Configuration bitstreams are not version-compatible, and you must generate all bitstreams from the same version of the Quartus Prime software.

After migrating the base revision to a later version of the Quartus Prime software, the bitstream you generate is only compatible with bitstreams from PR implementation compilations using that same Quartus Prime software version. Such a bitstream is incompatible with the PR bitstreams from an earlier version of the Quartus Prime software.

The Quartus Prime Pro Edition software supports version-compatible databases for PR designs for the following software versions and devices:

Table 11. Version-Compatible Compilation Database Support

The first table column indicates the first version to support version-compatible compilation database export for the specified devices.

Note:

- Database import supports two major versions back. For example, a database that you export from version 19.3, you can then import using version 19.3, 20.1, and 20.3. However, you cannot import version 19.3 to 21.1.
- You can export from any version that follows a supported version, if the version still supports the devices.

First Version with 'Export Design' Support	Stratix 10 and Devices	Arria 10 and Cyclone 10 GX Devices
18.0	No Support.	Supports all devices.
18.1	• 1SG250L • 1SG280H_S2 • 1SG280L • 1SG280L_S3 • 1SX250L • 1SX280L • 1SX280L_S3	Supports all devices.
19.1	• 1SM16BH • 1SM21BH • 1SM16CH • 1SM21CH • 1SM21KH • 1SM16KH • 1SM21LH • 1SM16LH	Supports all devices.
19.3	• 1SG10MH_U1 • 1SG10MH_U2 • 1ST250E • 1ST280E	Supports all devices.

continued...

First Version with 'Export Design' Support	Stratix 10 and Devices	Arria 10 and Cyclone 10 GX Devices
	• 1SM16E • 1SM21E • 1ST165E • 1ST210E • 1SG166H • 1SG211H	
20.1	• 1SD280P • 1ST040E • 1ST085E • 1ST110E	Supports all devices.
20.3	• 1SD21BP • 1SG040H • 1SX040H	Supports all devices.
20.4	• 1SN21BH • 1SN21CE	Supports all devices.

The following topics describe the version-compatible database generation flow and steps.

Version-Compatible Database Flow for PR Designs on page 68

Generating a Version-Compatible Compilation Database for PR Designs on page 69

Related Information

Quartus Prime Pro Edition User Guide: Getting Started
For more information on version-compatible compilation database file generation.

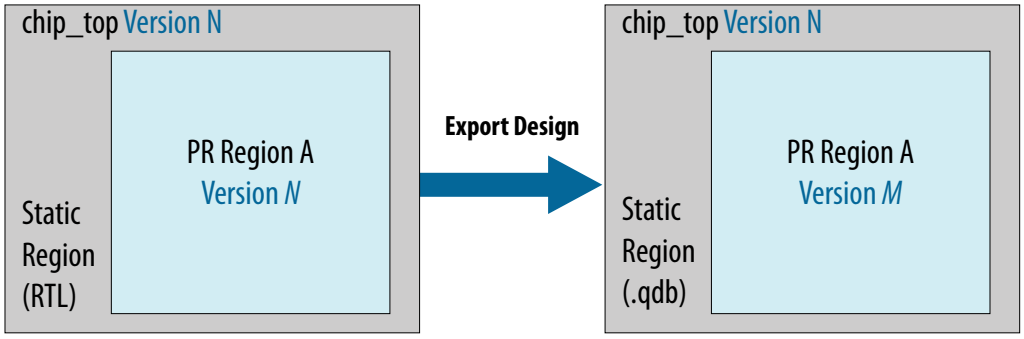
1.15.1. Version-Compatible Database Flow for PR Designs

Migrating a design with a single PR region involves the following high-level steps:

1. Perform initial compilation of the base revision in the Quartus Prime software version *N*.
2. Export a version-compatible database for the entire design in the Quartus Prime software version *N*.
3. Import the version-compatible database into the Quartus Prime software version *M (M>N)*.
4. Generate the base revision `.sof` file and bitstreams with the Quartus Prime Assembler version *M*.
5. Export the static region `.qdb` in the Quartus Prime software version *M*.
6. Perform a PR implementation compile in the Quartus Prime software version *M*.

Note: You must generate all of the PR bitstreams that you use with the Quartus Prime software version (*M*), including the full-chip configuration bitstream and the PR bitstream `.rbf`.

Figure 41. Static Region Migration (Single PR Region Compiled in Later Version)



1.15.2. Generating a Version-Compatible Compilation Database for PR Designs

Follow these steps to generate a version-compatible compilation database for PR designs:

1. Export the entire compiled design from the Quartus Prime software version *N* by clicking **Project ➤ Export Design**, or by command line:

```
quartus_cdb <project> -c <base_revision> --export_design --snapshot final \
     --file <base_revision>.qdb
```

2. Import the compiled design to the Quartus Prime software version *M* by clicking **Project ➤ Import Design**, or by command line:

```
quartus_cdb <project> -c <base_revision_import> --import_design --file \
     <base_revision>.qdb
```

   Note: Whenever possible, import the design into a different working directory than the directory that you use to compile the base design. If you must use the same directory for import and for compiling the base design, make a backup copy of your compiled design by archiving that design with `qdb/*` included, or make a copy of the entire directory and subdirectories elsewhere. You must also remove the old database directory `qdb/*` and all the bitstream related files (`*.sof`, `*.msf`, `*.pmsf`).

3. Rerun the finalize stage of the Fitter in the Quartus Prime Pro Edition software version *M* by clicking **Processing ➤ Start ➤ Start Fitter (Finalize)**, or by command line:

```
quartus_fit <project> -c <base_revision_import> --finalize
```

4. Run the Assembler in the Quartus Prime Pro Edition software version *M* to regenerate the static region bitstream by clicking **Processing ➤ Start ➤ Start Assembler**, or by command line:

```
quartus_asm <project> -c <base_revision_import>
```

5. Export the static region `.qdb` in the Quartus Prime Pro Edition software version *M* by clicking **Project ➤ Export Design Partition**, or by command line:

```
quartus_cdb <project> -c <base_revision_import> --export_block \
root_partition --snapshot final --file --include_sdc_entity_in_partition
static.qdb
```

Note: When exporting the base revision and the static partition, you must include any `.sdc` files that apply to the partition, by using the `include_sdc_entity_in_partition` option.

6. Compile each implementation revision in the Quartus Prime Pro Edition software version *M*, using the static revision `.qdb` that you exported in the previous step.

```
quartus_sh –flow compile <project> –c <impl_rev>
```

1.16. Creating a Partial Reconfiguration Design Revision History

Document Version	Quartus Prime Version	Changes
2023.04.01	24.1	• Applied initial Altera rebranding throughout. • Updated throughout to reflect support for Agilex 5 devices.
2023.07.31	23.2	• Added *Understanding PR Logic Utilization Reports* topic to describe interpretation of logic utilization values.
2023.06.30	23.2	• Updated *What's New In This Version* topic for current changes that impact this document. • Noted requirement that you must use global clock resources to clock M20K RAMs in PR regions for Agilex 7 devices in *Partial Reconfiguration Design Considerations* topic.
2023.06.26	23.2	• Updated *What's New In This Version* topic for current changes that impact this document. • Removed obsolete *Partial Reconfiguration M20K Protection Methodology for Intel Agilex 7 Devices* appendix.
2023.04.03	23.1	• Updated *What's New In This Version* topic for current changes that impact this document. • Updated product family name to "Intel Agilex 7."
2022.08.05	22.2	• Updated *What's New In This Version* topic to note speed grade, compression, and encryption limitation removal. All speed grades support PR. Compression is always enabled for Intel Agilex devices and Intel Stratix 10 devices. Encryption is supported as part of the bitstream security feature for these devices. • Added note about avoiding overlapping routing regions to *Step 3: Floorplan the Design* topic. • Removed speed grade limitations from *Partial Reconfiguration Design Considerations* topic. • Added footnote to *Partial Reconfiguration Design Guidelines* topic clarifying need to sometimes reset data registers. • Corrected figure highlight in *Viewing Row Clock Region Boundaries* topic. • Revised statement about need to install specific IP for debugging the PR region in *Debugging PR Regions with the Signal Tap Logic Analyzer* topic. • Revised *Implementing Clock Enable for On-Chip Memories with Initialized Contents* for requirement to gate appropriately the Clock Enable signal in some cases. • Removed note stating no support for PR bitstream encryption and compression for Intel Agilex devices nor Intel Stratix 10 devices. Compression is always enabled by default for Intel Agilex devices and Intel Stratix 10 devices. Encryption is supported as part of the security feature.
2022.01.11	21.4	• Add Top FAQs navigation to the cover page. • Minor wording changes to *Partial Reconfiguration Terminology* table. • Added *What's New in this Version* topic.

continued...

Document Version	Quartus Prime Version	Changes
		• Added clarifying notes to image in *Viewing Row Clock Region Boundaries* topic. • Added note about pin assignments deriving from only from the base revision to *Step 3: Floorplan the Design* and *Step 8: Setup Implementation Revisions Viewing Row Clock Region Boundaries* topic. • Added notes about the relationship between sector coverage and reconfiguration time to *Step 3: Floorplan the Design* topic. • Removed Post Synthesis Export File substep from *Step 7: Compile the Base Revision and Export the Static Region* topic. • Corrected typo and added note to *Step 8: Setup PR Implementation Revisions* topic. • Revised *Generating PR Bitstream Files* topic to refer to Convert Programming Files dialog box. • Corrected steps in *Generating a Version-Compatible Compilation Database for PR Designs* topic.
2021.10.04	21.3	• Updated *PR Bitstream Security Validation* topic to refer to Programming File Generator and revise figure. • Updated *PR File Management* topic for new QSF assignment method. • Clarified device support and corrected code example in *Generating a Merged .pmsf File from Multiple .pmsf Files* topic. • Revised *Version-Compatible Database Flow for PR Designs* topic equation and figure. • Updated non-inclusive terms with "host" and "agent" for Avalon Memory Mapped interface references throughout.
2021.08.02	21.2	• Updated *Register States and Programming Model* diagram. • Updated *Avoiding PR Programming Errors* topic SEU note.
2021.06.21	21.2	• Updated *Version-Compatible Compilation Database Support* table.
2021.05.06	21.1	• Indicated support for Agilex 7 design PR bitstream generation, and removed PR bitstream generation limitation notes. • Revised *Partial Reconfiguration Design Debugging* topic. • Revised *Debugging PR Designs with the Signal Tap Logic Analyzer* topic. • Added new *Instantiating the Intel Configuration Reset Release Endpoint to Debug Logic* topic. • Updated *Partial Reconfiguration Security* topic for latest information. • Updated *PR Bitstream Security Validation* topic license statement and to remove outdated references. • Revised *PR Authentication* topic use cases. • Revised *PR Authentication* topic use cases. • Revised *PR Bitstream Encryption* topic use case and prerequisites.
2020.12.11	20.3	• Corrected typo in PMSF file definition in "Using PR Bitstream Security Verification"
2020.09.28	20.3	• Added note about preserving SDC files to "Step 8: Setup PR Implementation Revisions" topic. • Added new "Using Parent QDB Files from Different Compiles" topic. • Added "PR Design Timing Closure Best Practices" topic. • Replaced references to Avalon-MM and Avalon-ST with Avalon memory-mapped and Avalon streaming for legal compliance.

Document Version	Quartus Prime Version	Changes
		• Corrected description of Entity Re-binding option in *Design Partition Settings* table. • Added command line instructions for creating a revision. • Stated PR compilation flow support for Cyclone 10 GX devices. • Updated Partial Reconfiguration Controller Arria 10 FPGA IP name to Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP. • Added "Viewing Row Clock Region Boundaries." • Added "Planning Clocks and other Global Routing."
2018.07.18	18.0.0	• Corrected signals in *Simulation of PR Persona Switching* diagram.
2018.06.18	18.0.0	• Corrected syntax errors and added note in *Running Timing Analysis on Aggregate Revisions*.
2018.05.29	18.0.0	• Added description of "|" that identifies the root partition hierarchy path in Design Partitions Window. • Clarified .qsf assignment in *Running Timing Analysis on Aggregate Revisions*.
2018.05.07	18.0.0	• Added description of new Partial Reconfiguration External Configuration Controller Stratix 10 FPGA IP. • Removed descriptions of obsolete synthesis-only revisions and corresponding personas. Replaced with latest simplified flow instructions. • Updated names of Partial Reconfiguration Controller Arria 10 FPGA IP and Partial Reconfiguration Controller Stratix 10 FPGA IP. • Added *Design Partition Settings* topic. • Added *Evaluating PR Partition Initial Conditions* topic. • Added *Avoiding PR Programming Errors* topic. • Described qcrypt incompatibility with Enable bitstream compatibility check and workaround. • Added as chapter in new *Partial Reconfiguration User Guide*. • Updated command-line syntax in *Running Timing Analysis on Aggregate Revisions* topic. • Removed obsolete HPR flow script information and linked to *AN826: Hierarchical Partial Reconfiguration Tutorial for Intel Stratix 10 GX FPGA Development Board* • Added note about recovery after PR error when using SEU detection in Stratix 10 designs.
2017.11.06	17.1.0	• Added partial reconfiguration support for Stratix 10 devices. • Added descriptions of Stratix 10 Partial Reconfiguration Controller IP, SUPR, HPR, and SDM to terms list. • Updated for latest Intel branding and software user interface.
2017.05.08	17.0.0	• Added information about Hierarchical Partial Reconfiguration. • Added new topic Partial Reconfiguration Simulation and Verification. • Added new topic 'Run Timing Analysis on a Design with Multiple PR Partitions'. • Updated Freeze Logic for PR Regions. • Added new topic Debugging Using Signal Tap Logic Analyzer. • Other minor updates.
10.31.2016	16.1.0	• Initial release.

2. Partial Reconfiguration Solutions IP User Guide

The Quartus Prime Pro Edition software includes the following Intel FPGA IP cores that simplify partial reconfiguration implementation.

Instantiate one or more of these IP cores to implement handshake and freeze logic for PR functionality in your design. Alternatively, create your own PR handshake and freeze logic that interfaces with the PR region.

Table 12. Partial Reconfiguration IP Cores

Intel FPGA IP	Description	Usage
Partial Reconfiguration Controller Intel FPGA IP	Dedicated IP component that sends the partial reconfiguration bitstream for the Agilex 7, Agilex 5, or Stratix 10 FPGA. The PR bitstream performs reconfiguration by adjusting CRAM bits in the FPGA.	One instance per Stratix 10, Agilex 5, or Agilex 7 FPGA
Partial Reconfiguration External Configuration Controller Intel FPGA IP	IP component that supports Stratix 10 and Agilex 7 FPGA partial reconfiguration via an external source over dedicated PR pins.	One instance per Stratix 10, Agilex 5, or Agilex 7 FPGA for external configuration
Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP	Dedicated IP component that sends the partial reconfiguration bitstream to the Arria 10 or Cyclone 10 GX FPGA. The PR bitstream performs reconfiguration by adjusting CRAM bits in the FPGA.	One instance per Arria 10 or Cyclone 10 GX FPGA, internal or external configuration.
Partial Reconfiguration Region Controller Intel FPGA IP	Provides a standard Avalon memory-mapped interface to the block that controls handshaking with the PR region. Ensures that PR region stops, resets, and restarts, according to the PR handshake.	One instance per PR region.
Avalon Memory-Mapped Partial Reconfiguration Freeze Bridge Intel FPGA IP	Provides freeze capabilities to the PR region for Avalon memory-mapped interfaces.	One instance for each interface in each PR region.
Avalon Streaming Partial Reconfiguration Freeze Bridge Intel FPGA IP	Provides freeze capabilities to the PR region for Avalon streaming interfaces.	One instance for each interface in each PR region.

2.1. Internal and External PR Host Configurations

You perform PR with either an internal host residing in the core resources, or with an external host via dedicated device pins. Use of an internal host stores all PR host logic on the FPGA device, rather than on an external device. The PR host interfaces with the control block through simple handshaking and data transfer.

Figure 42. Arria 10 and Cyclone 10 GX Partial Reconfiguration IP Components (Internal Host)

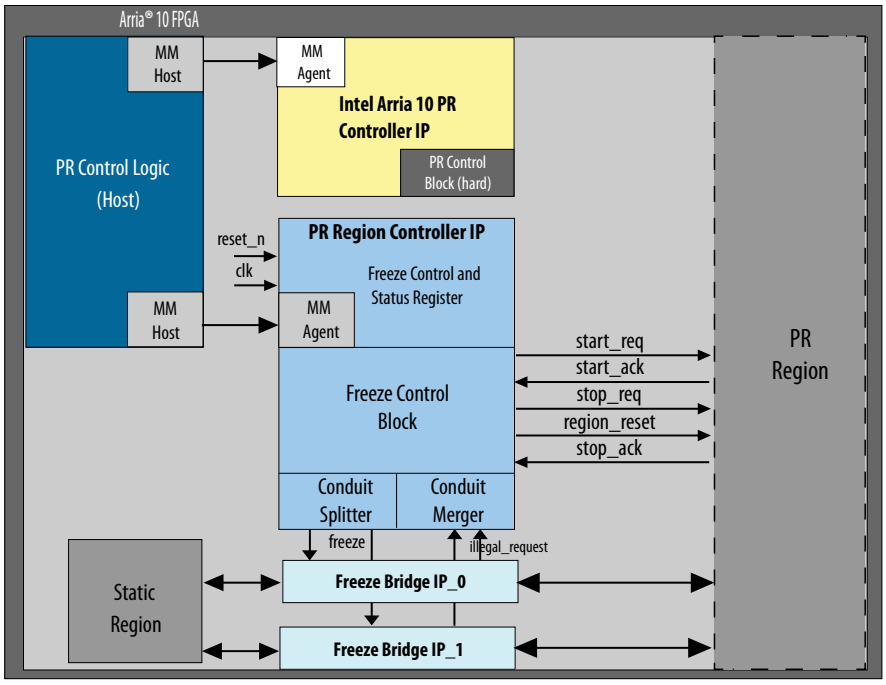

Figure 43. Agilex 7, Agilex 5, and Stratix 10 Partial Reconfiguration IP Components for (Internal Host)

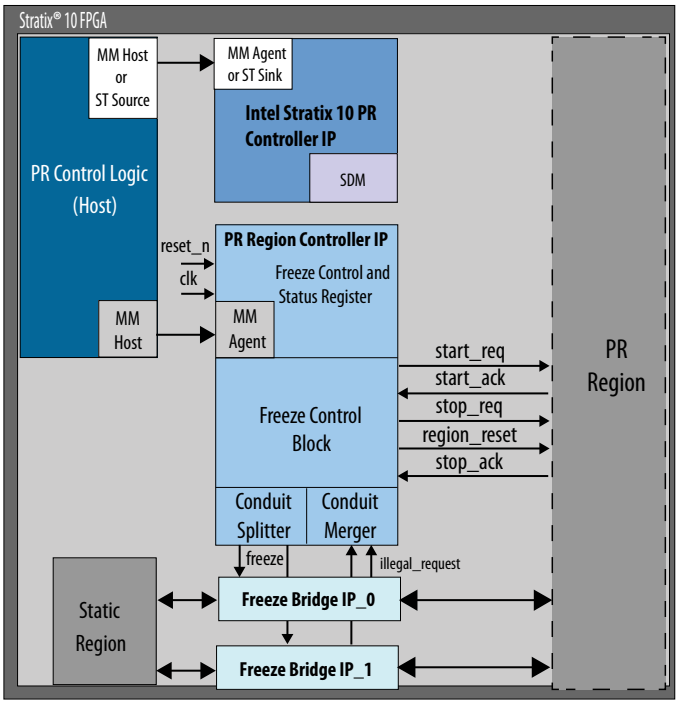

Figure 44. Partial Reconfiguration with Microcontroller External Host (Arria 10 or Cyclone 10 GX device)

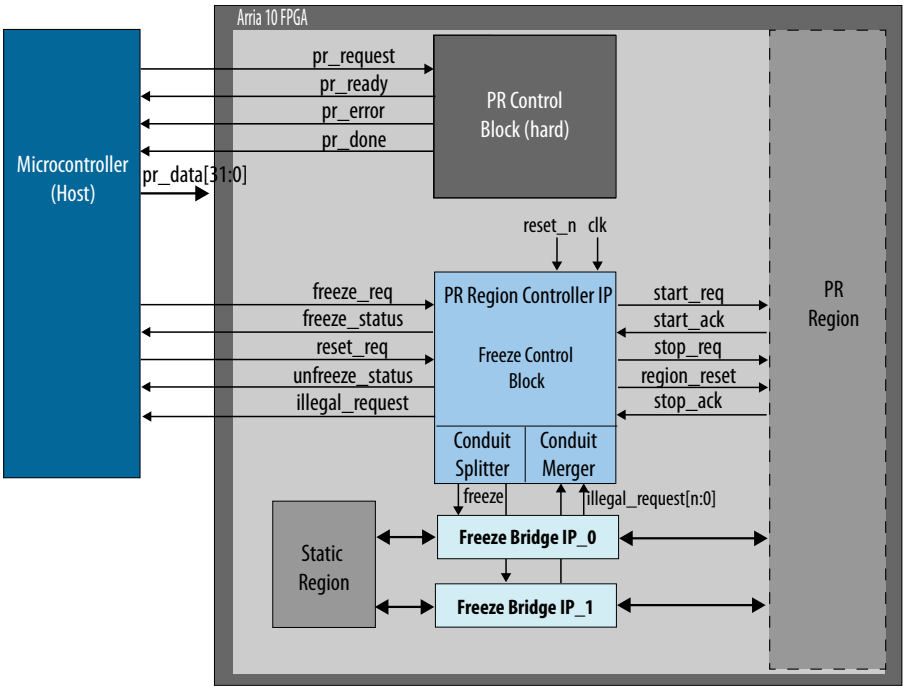

Figure 45. Partial Reconfiguration with HPS Internal Host (Arria 10 or Cyclone 10 GX device)

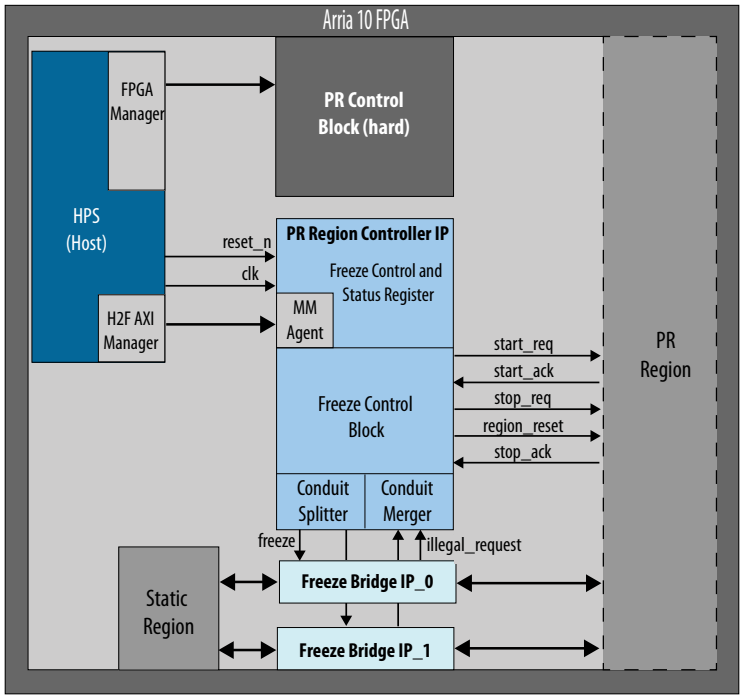
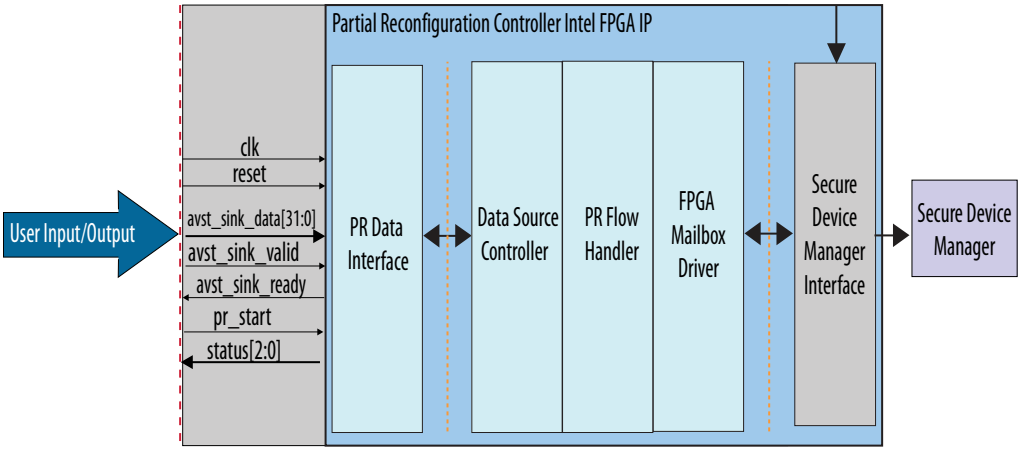


2.2. Partial Reconfiguration Controller Intel FPGA IP

The Partial Reconfiguration Controller Intel FPGA IP provides partial reconfiguration functionality for Stratix 10 and Agilex 7 designs. The IP core provides a standard interface to the FPGA secure device manager (SDM), and has a maximum clock frequency of 200 MHz.

Figure 46. Partial Reconfiguration Controller Avalon Streaming Interface (Agilex 7, Agilex 5, and Stratix 10 Designs)

(5)



Note: If an error occurs during PR operation for an Agilex 7, Agilex 5, or Stratix 10 design using SEU detection, the PR region is frozen, becomes non-functional, and SEU detection is disabled for all sectors within the PR region and certain sectors adjacent to PR region. To resolve this error and restore SEU detection on affected areas, perform a full chip configuration.

2.2.1. Memory Map

The Partial Reconfiguration Controller Intel FPGA IP has the following memory map.

Table 13. Avalon Memory-Mapped Slave Memory Map

Name	Address Offset	Width	Access	Description
PR_DATA	0x00	32	Write	Every data `write` to this address indicates this bitstream is sending to the IP core. Width is set by the **Input data width** parameter.
PR_CSR	0x01	32	Read or Write	Control and status registers with the following offset bits:

continued...

(5) Avalon memory mapped interface variant also available.

Name	Address Offset	Width	Access	Description
				• 31 - 7: Reserved. • 6: Protocol violation. This bit is asserted when the Avalon memory-mapped or Avalon streaming protocol is violated. • 5: Read/Write for `irq` signal mask bit. Write `1` to this bit enable `irq` signal and `0` to disable the `irq` signal. • 4: Read/Clear for `irq` signal. The `irq` signal asserts if an error occurs. The Master must read the status signal and clear the interrupt by writing `1` to this bit. • 3 - 1: Read-only for `status` signal. • 0: Read/Write for `pr_start` signal. To streamline the flow, the IP core automatically de-asserts to value `0`, one clock cycle after the signal asserts.
PR_SW_VER	0x02	32	Read	Read-only SW version register. Register is currently 0xBA500000.
PR_FW_HANDSHAKE	0x03	32	Read	Current location of mailbox handshake between the PR IP and the SDM in the PR operation with the following offset bits: • 31 - 8: Reserved. • 7 - 0: Current location of the mailbox handshake between the PR IP and the SDM.
PR_FW_RESPONSE	0x04	32	Read	SDM mailbox response. You must use this in conjunction with PR_FW_HANDSHAKE. If PR_FW_HANDSHAKE is `0x2` or `0x6`, the following offset bits apply: • 31 - 11: Reserved. • 10 - 0: Response header of the response payload. If PR_FW_HANDSHAKE is 0x4, the following offset bit applies: • 31 - 0: First response word of response payload.

Note: For IP core instantiation guidelines, refer to the appropriate device configuration user guide.

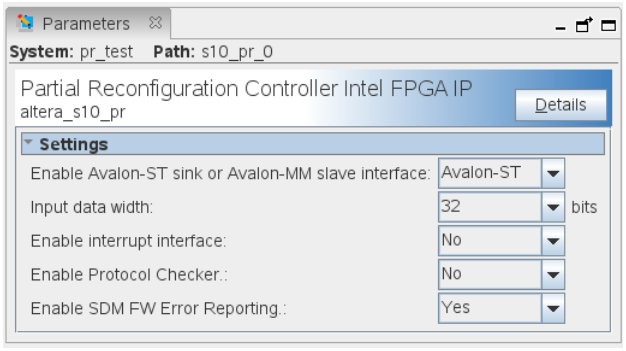
2.2.2. Parameters

The Partial Reconfiguration Controller Intel FPGA IP supports customization of the following parameters.

Table 14. Partial Reconfiguration Controller Intel FPGA IP Parameter Settings

Parameter	Value	Description
Enable Avalon-ST sink or Avalon-MM slave interface	**Avalon-ST/Avalon-MM**	Enables the controller's Avalon streaming sink or Avalon memory-mapped agent interface.
Input data width	*<bits>*	Specifies the size of the controller's data conduit interface in bits. The IP supports device widths of 32 and 64. The Avalon memory-mapped slave interface supports 32-bits only.
Enable interrupt interface	**Yes/No**	Enables interrupt assertion for detection of incompatible bitstream, CRC_ERROR, PR_ERROR, or successful partial reconfiguration. Upon interrupt, query PR_CSR[3:1] for status. Write a 1 to PR_CSR[4] to clear the interrupt. Use only together with the Avalon memory-mapped agent interface.
Enable Protocol Checker	**Yes/No**	Reads out the error bit from the CSR register (PR_CSR[6]).
Enable SDM FW Error Reporting	**Yes/No**	Enables the SDM firmware error reporting ports and CSR. Enables the additional pr_fw_handshake and pr_fw_response ports in Avalon streaming mode, and can be read out from the CSR register (base address offsets 3 and 4) in Avalon memory-mapped mode. *Note:* This parameter is only supported for Agilex 7 and Agilex 5 devices.

Figure 47. Parameter Editor



2.2.3. Ports

The Partial Reconfiguration Controller Intel FPGA IP includes the following interface ports.

Figure 48. Avalon Streaming Sink Interface Ports

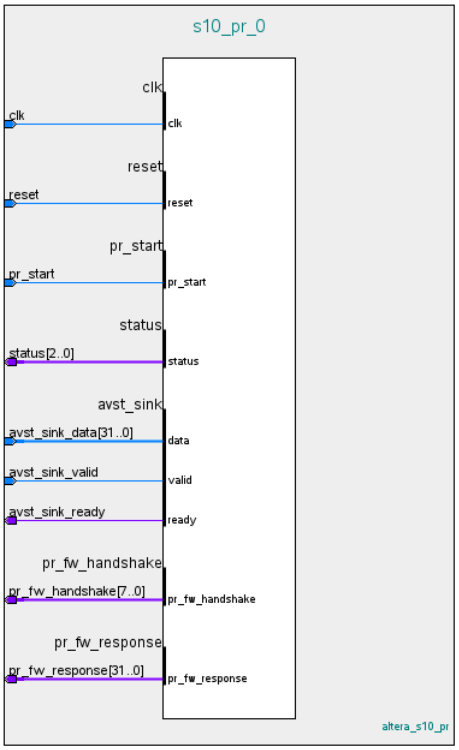


Figure 49. Avalon Memory-Mapped Agent Interface Ports

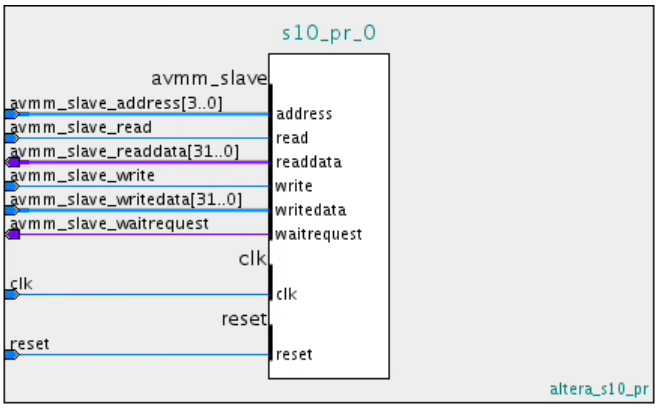
(6)



(6) The terms host and agent now replace non-inclusive terms in the Avalon Memory Mapped specification.

Table 15. Clock/Reset Ports

Port Name	Width	Direction	Function
reset	1	Input	Asynchronous reset for the PR Controller IP core. Resetting the PR Controller IP core during a partial reconfiguration operation can cause the device to lock up.
clk	1	Input	Input clock to the PR Controller IP core. The input clock must be free-running. The IP core has a maximum clock frequency of 200 MHz.

Table 16. Avalon Streaming Sink interface Ports

These ports are available when you enable the **Avalon Streaming** sink interface.

Port Name	Width	Direction	Function
pr_start	1	Input	A signal arriving at this port asserted high initiates a PR event. You must assert this signal high for a minimum of one clock cycle, and de-assert it low, prior to the end of the PR operation.
avst_sink_data[]	32|64	Input	Avalon streaming data signal that is synchronous with the rising edge of the clk signal. The **Input data width** parameter specifies this port width.
avst_sink_valid	1	Input	Avalon streaming data valid signal that indicates the avst_sink_data port contains valid data.
avst_sink_ready	1	Output	Avalon streaming ready signal that indicates the device is ready to read the streaming data on the avst_sink_data port whenever the avst_sink_valid signal asserts high. Stop sending valid data when this port is low.
status[2:0]	3	Output	A 3-bit error output that indicates the status of a PR event. Once the outputs latch high as follow, you can only reset the outputs at the beginning of the next PR event: 3'b000 – power-up nreset asserted 3'b001 – configuration system is busy 3'b010 – PR operation is in progress 3'b011 – PR operation successful 3'b100 – PR_ERROR is triggered 3'b101 – Reserved 3'b110 – Incompatible bitstream error 3'b111 – Reserved
protocol_error	1	Output	Reads out the error bit from the CSR register.
pr_fw_handshake	8	Output	Indicates the current state of the mailbox handshake between the PR IP and the SDM firmware in the PR operation.
pr_fw_response	32	Output	SDM firmware mailbox response.

Table 17. Avalon Memory-Mapped Agent Interface Ports

These ports are available when you enable the **Avalon memory-mapped** agent interface.

Port Name	Width	Direction	Function
avmm_slave_address	4	Input	Avalon memory-mapped address bus in the unit of Word addressing.
avmm_slave_read	1	Input	Avalon memory-mapped read control.

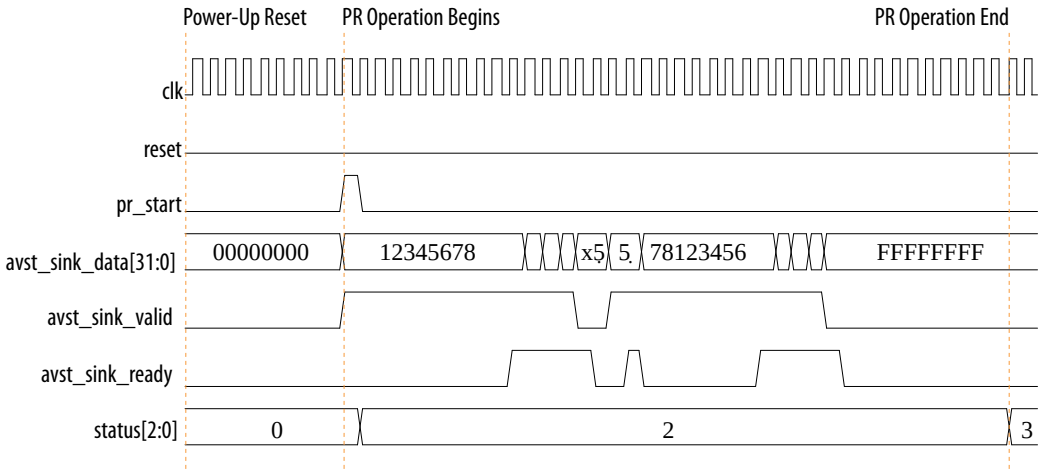
continued...

Port Name	Width	Direction	Function
avmm_slave_readdata	32	Output	Avalon memory-mapped read data bus.
avmm_slave_write	1	Input	Avalon memory-mapped write control.
avmm_slave_writedata	32	Input	Avalon memory-mapped write data bus.
avmm_slave_waitrequest	1	Output	Upon assertion, indicates that the IP is busy and the IP is unable to respond to a read or write request.
irq	1	Output	Interrupt signal when you enable the **Enable interrupt interface** parameter.

2.2.4. Timing Specifications

The following timing diagram illustrates a successful PR operation with the Partial Reconfiguration Controller Intel FPGA IP. The `status[2:0]` output signal indicates whether the operation passes or fails. The PR operation initiates upon assertion of the `pr_start` signal. Monitor the `status[]` signal to detect the end of the PR operation.

Figure 50. Timing Specifications



2.2.5. PR Error Recovery

The Partial Reconfiguration Controller Intel FPGA IP supports error recovery during partial reconfiguration.

Note: PR error recovery is only supported for Agilex 7 and Agilex 5 devices.

When PR_ERROR triggers, the PR Controller IP initiates the error recovery mechanism by de-asserting the `avst_sink_ready` signal to flush out any remaining corrupted PR bitstream that remains in the Avalon streaming pipeline.

Note: You must ensure that the remaining corrupted PR bitstream is fully flushed from the Avalon streaming pipeline before initiating another PR operation, or before performing a PR controller IP reset.

For PR Controller IP designs that have an Avalon memory-mapped interface, when PR_ERROR is triggered, continue to write (by asserting both `avmm_slave_write` and `avmm_slave_writedata`) until the PR bitstream in the Avalon memory-mapped host depletes.

To prevent inadvertent flushing of the new bitstream, do not provide a new, uncorrupted PR bitstream to the PR Controller IP until flushing is complete. Once flushing is complete, you can send a new, uncorrupted PR bitstream to the PR controller IP when `pr_start` is asserted and after the reset is de-asserted.

Note: Once the PR process initiates, you cannot alter nor replace the PR bitstream provided in the Avalon streaming pipeline. For example, if the PR Controller IP reflects a status of configuration is busy (`3'b001`), you must re-initiate PR with the PR bitstream that is already present, without replacing the bitstream. The existing PR bitstream must undergo the whole PR process until the PR operation completes with status of either success (`3'b011`) or fail (PR_ERROR is triggered: `3'b100`, or incompatible bitstream error: `3'b110`) with the error recovery mechanism to clear the Avalon streaming pipeline.

After one of the statuses occurs, you can send the PR bitstream to the PR Controller IP when initiating another PR operation, or after performing a PR Controller IP reset.

This PR error recovery feature is available only for the Partial Reconfiguration Controller Intel FPGA IP, which controls Avalon streaming and Avalon memory-mapped paths where the data comes in.

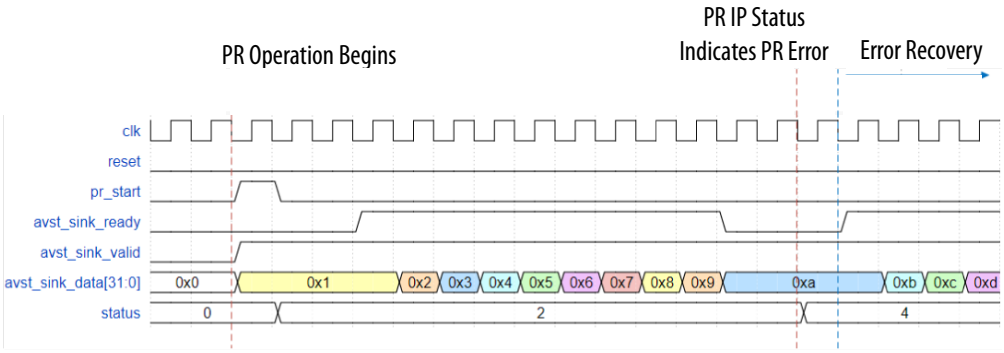
The Partial Reconfiguration Controller Intel FPGA IP only acts as a block that reports the handshaking of the external user host and the SDM of the FPGA. There is no interaction between the streaming path and the IP. You connect directly to the Avalon streaming pins in the SDM I/O. These SDM I/O pins are exactly the same as the Avalon Streaming pins that you use for full device configuration. The PR IP cannot control the SDM I/O pins.

2.2.5.1. PR Error Recovery Timing Specifications

The following describes the timing specifications for PR error recovery.

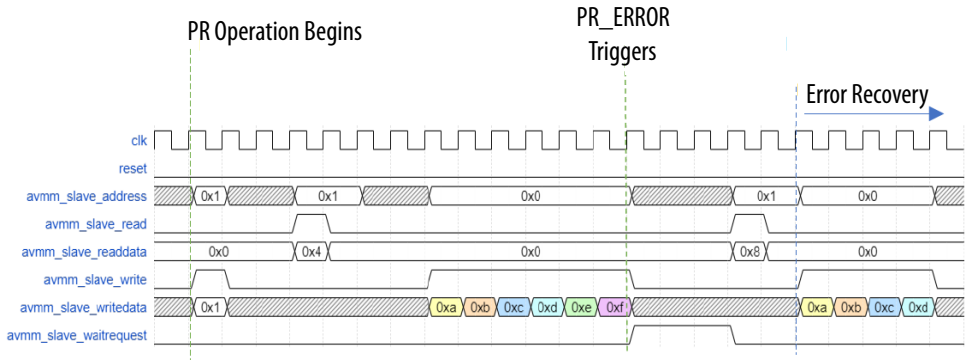
Timing Diagram: PR Operation with PR_ERROR Triggered - PR Controller Intel FPGA IP (Avalon Streaming), and Timing Diagram: PR Operation with PR_ERROR Triggered - PR Controller Intel FPGA IP (Avalon Memory-Mapped) describe a PR operation that encounters PR_ERROR. When PR_ERROR is triggered, the FPGA SDM operation de-asserts the `avst_sink_ready` signal to backpressure any remaining corrupted PR bitstream. Next, the error recovery mechanism initiates by re-asserting the `avst_sink_ready` signal to flush out any remaining corrupted PR bitstream in the Avalon streaming pipeline.

Figure 51. Timing Diagram: PR Operation with PR_ERROR Triggered - PR Controller Intel FPGA IP (Avalon Streaming)



For PR Controller IP designs that have the Avalon memory-mapped interface, when PR_ERROR triggers, continue to write (by asserting both `avmm_slave_write` and `avmm_slave_writedata`) until the PR bitstream in the Avalon memory-mapped host depletes, as Timing Diagram: PR Operation with PR_ERROR Triggered - PR Controller Intel FPGA IP (Avalon Memory-Mapped) shows.

Figure 52. Timing Diagram: PR Operation with PR_ERROR Triggered - PR Controller Intel FPGA IP (Avalon Memory-Mapped)



The error recovery mechanism continues until you initiate a PR Controller IP reset or another PR operation, as the following illustrations show. Then, you can send a new, uncorrupted PR bitstream to the PR Controller IP.

Note: Do not provide the new, uncorrupted PR bitstream to the PR Controller IP before reset or `pr_start` to prevent flushing the new bitstream during error recovery.

Figure 53. Timing Diagram: Error Recovery Until Reset Assert - PR Controller Intel FPGA IP (Avalon Streaming)

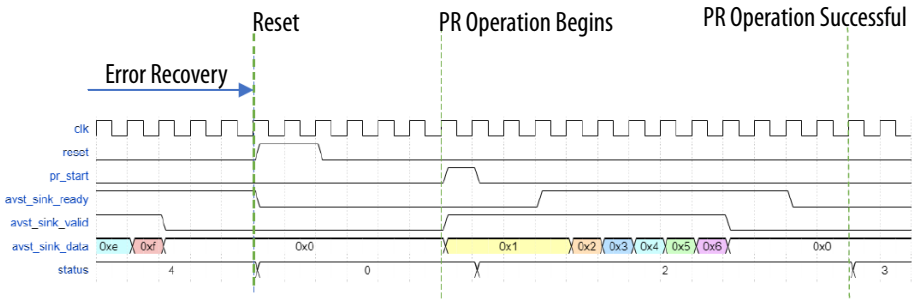


Figure 54. Timing Diagram: Error Recovery Until Reset Assert - PR Controller Intel FPGA IP (Avalon Memory-Mapped)

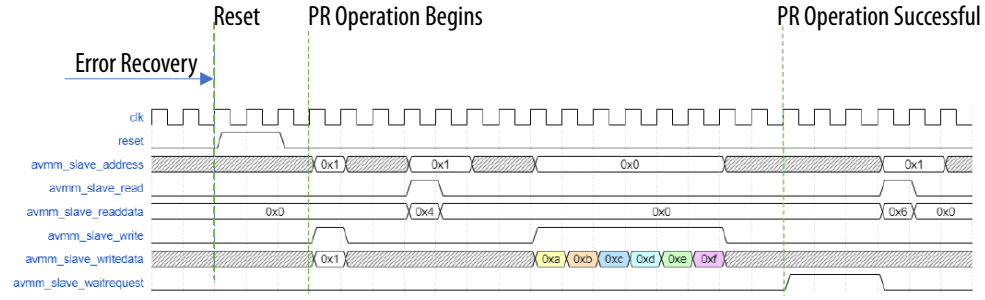

Figure 55. Timing Diagram: Error Recovery Until PR Operation Initiates - PR Controller Intel FPGA IP (Avalon Streaming)

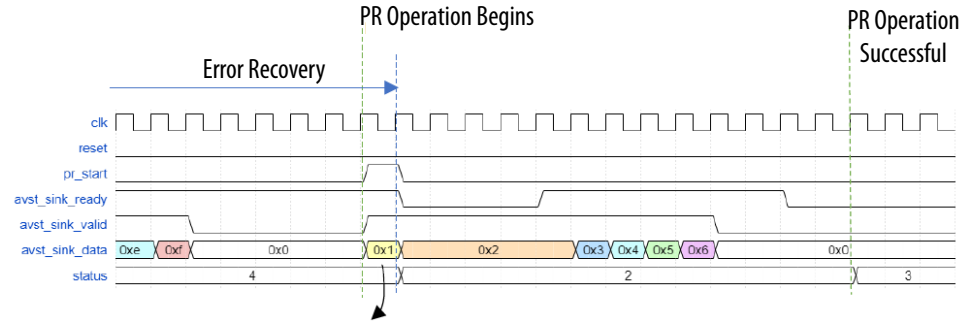
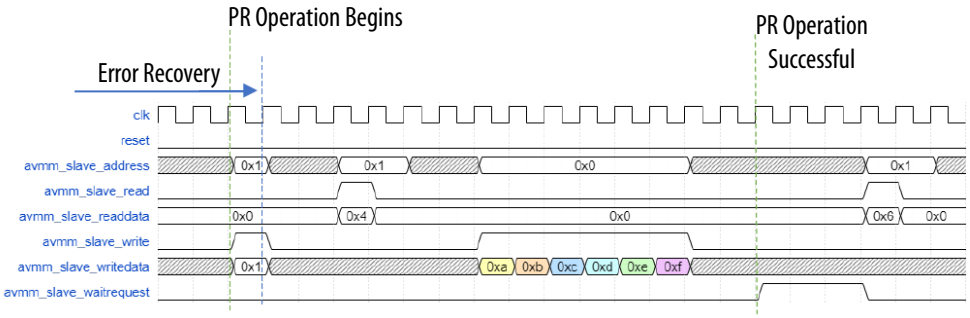


Note: In a scenario where you provide a new, uncorrupted PR bitstream to `avst_sink_data` at the same clock cycle that PR operation initiates, the internal register captures the first beat of data (`0x1`) because of error recovery.

Figure 56. Timing Diagram: Error Recovery Until PR Operation Initiates - PR Controller Intel FPGA IP (Avalon Memory-Mapped)



2.2.6. Secure Device Manager Firmware Error Reporting

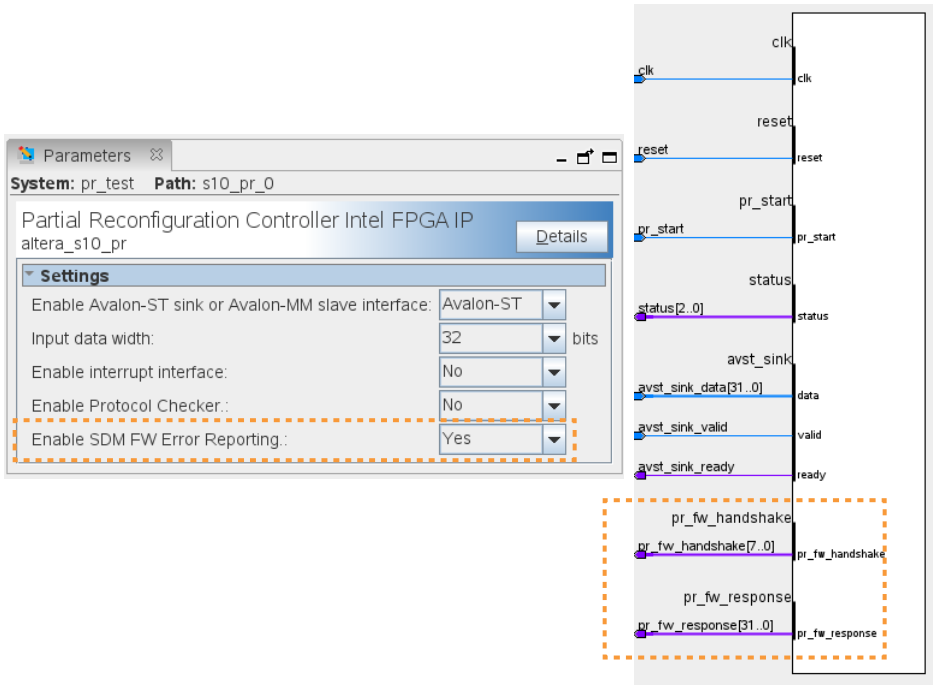
The Partial Reconfiguration Controller Intel FPGA IP notifies you of a non-specific error in PR operation by updating the 3-bit `status` CSR port to a generic PR_ERROR or "Incompatible bitstream error" in the PR controller IP. However, this error notification does not include specific details about the nature of the error.

As the secure device manager (SDM) firmware processes the PR bitstream, the SDM firmware error reporting can provide details about the error, such as the PR stage where the error occurs. You can use this information to identify and resolve any issue before re-attempting another PR operation on the PR region that remains isolated from an initial, failed PR attempt. If the SDM firmware reports no error, then the PR error is outside of the SDM firmware.

Note: SDM firmware error reporting is only supported for Agilex 7 and Agilex 5 devices.

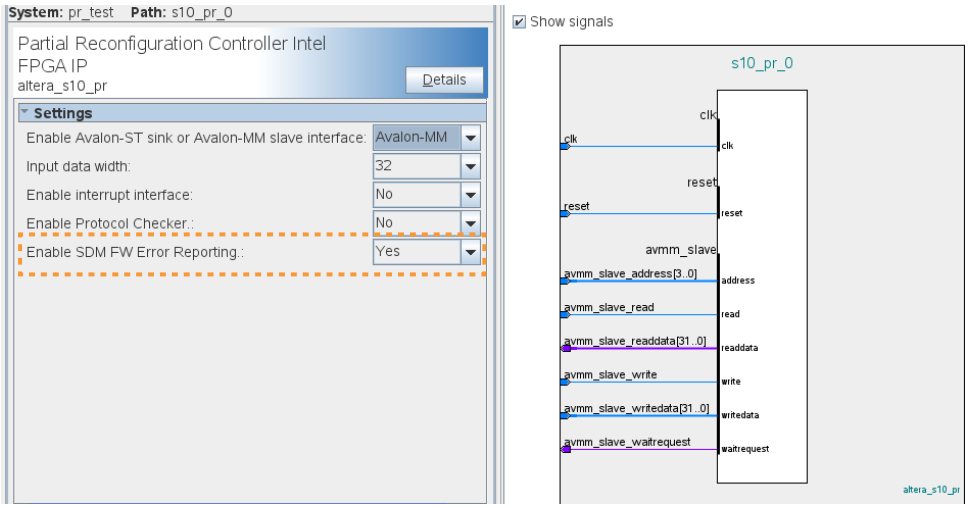
PR IP in Avalon Streaming Mode with SDM Firmware Error Reporting Enabled shows the IP in Avalon streaming mode with SDM firmware error reporting enabled. Enabling this parameter adds the `pr_fw_handshake[7:0]` and `pr_fw_response[31:0]` ports to the IP.

Figure 57. PR IP in Avalon Streaming Mode with SDM Firmware Error Reporting Enabled



Similarly, PR IP in Avalon Memory-Mapped Mode with SDM Firmware Error Reporting Enabled shows the IP in Avalon memory-mapped mode with SDM firmware error reporting enabled by the PR_FW_HANDSHAKE[0x3] and PR_FW_RESPONSE[0x4] CSR registers of the Avalon memory-mapped register map. Enabling this parameter adds no additional ports.

Figure 58. PR IP in Avalon Memory-Mapped Mode with SDM Firmware Error Reporting Enabled

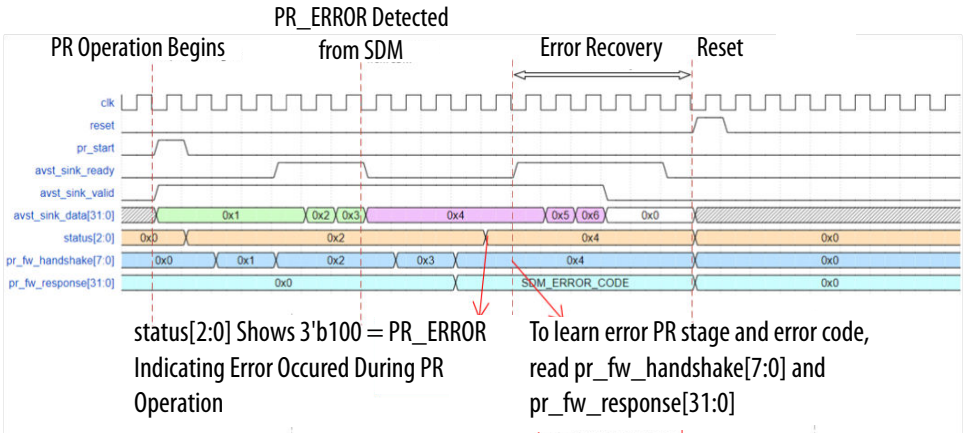


2.2.6.1. SDM Firmware Error Reporting Timing Specification

Timing Diagram: PR Operation with SDM Firmware Error Reporting Signals - PR Controller Intel FPGA IP (Avalon Streaming) shows the timing diagram of PR operation with the SDM firmware error reporting signal usage in Avalon-ST mode of the PR Controller IP. During PR operation, you can read the `pr_fw_handshake` and `pr_fw_response` signals after a PR error to learn more about the error. For example, once you detect the PR operation has ended with the `status[2:0]`, you can continue by reading the `pr_fw_handshake` and `pr_fw_response` signals.

In this example, the PR operation ends with PR_ERROR, as indicated by the `status[2:0] = 3'b100`. For error details, you can read the `pr_fw_handshake` to determine in which stage the PR operation fails. You can read `pr_fw_response` to determine the error code that the SDM returns.

Figure 59. Timing Diagram: PR Operation with SDM Firmware Error Reporting Signals - PR Controller Intel FPGA IP (Avalon Streaming)



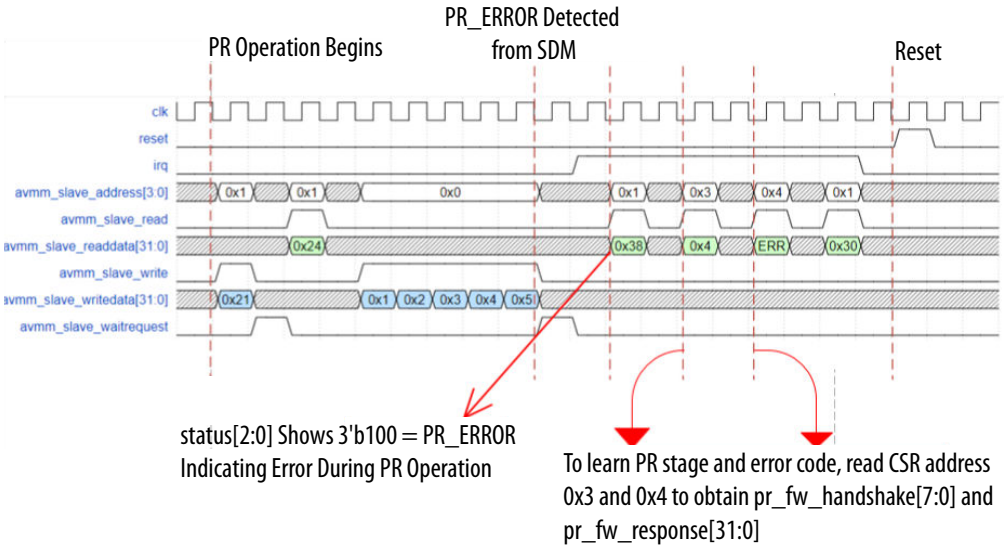
The following steps correspond to the sequence in the timing diagram:

1. Assert `pr_start` to begin the PR operation.
2. Stream the PR bitstream on `avst_sink_ready` and `avst_sink_valid` ports.
3. The SDM detects a PR_ERROR causing `avst_sink_ready` to be de-asserted to backpressure incoming PR bitstream.
4. You detect that `status[2:0]` is updated to `0x4 (3'b100)` to indicate that 'PR_ERROR is triggered'. From this status information, you can determine that an error occurred during the PR operation.
5. To learn more about the PR operation failure, read the `pr_fw_handshake[7:0]` and `pr_fw_response[31:0]` signals to determine the error code and PR stage of the failure.

Timing Diagram: PR Operation with SDM Firmware Error Reporting Signals - PR Controller Intel FPGA IP (Avalon Memory-Mapped) shows the PR operation timing diagram with the SDM firmware error reporting signal usage in Avalon memory-mapped mode of the PR Controller Intel FPGA IP. During a PR operation, you can read the CSR registers (`0x3` for PR_FW_HANDSHAKE, and `0x4` for PR_FW_RESPONSE) after a PR error to learn more about the error. For example, once you detect that the PR

operation ends with an error by IRQ assertion, and after reading CSR register 0x1 (PR_CSR) that holds the PR status[2:0] value, you can continue by reading the CSR registers 0x3 and 0x4, as .

Figure 60. Timing Diagram: PR Operation with SDM Firmware Error Reporting Signals - PR Controller Intel FPGA IP (Avalon Memory-Mapped)



The following steps correspond to the sequence in the timing diagram:

1. Start the PR operation by writing to CSR address 0x1 (PR_CSR) with 0x21.This action enables the use of the irq signal and sets the pr_start to begin the PR operation. After 1 clock cycle, status[2:0] updates to 0x2 (3'b010) to indicate 'PR operation is in progress'.
2. Read the CSR address 0x1 (PR_CSR) to obtain the status[2:0] of the PR operation. The value read back is 0x24, which translates to status[2:0] = 3'b010, indicating 'PR operation is in progress'.
3. Start writing the PR bitstream in CSR address 0x0 (PR_DATA).
4. You read PR_CSR and observe that irq was asserted and that PR_ERROR is the status.

The pr_fw_handshake register holds the current location of the mailbox handshake between the PR IP and the SDM. If the PR IP is interrupted during PR, the pr_fw_handshake register indicates the last position of the mailbox handshake. The pr_fw_handshake register also enables you to associate the value held in pr_fw_response to a specific mailbox command.

Table 18. pr_fw_handshake Register Values

Register Value	Description
0	The PR IP has not yet sent any mailbox command to the SDM to initiate the partial reconfiguration operation.
1	The PR IP has sent the mailbox command to the SDM to initiate the partial reconfiguration operation and is awaiting a response.

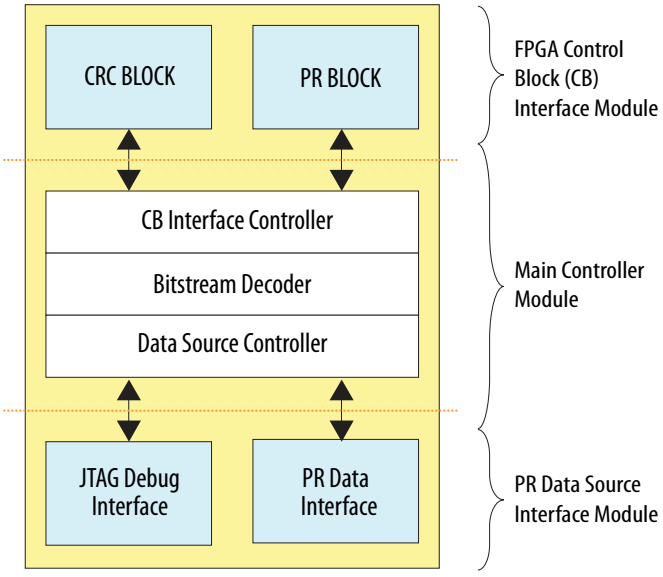
continued...

Register Value	Description
2	PR IP has received the mailbox response from the SDM on the partial reconfiguration operation initiation.
3	The PR IP has sent the mailbox command to the SDM to query the last partial reconfiguration status and is awaiting a response.
4	The PR IP has received the mailbox response from the SDM on the last partial reconfiguration status.
5	The PR IP has sent the mailbox command to the SDM to initiate the partial reconfiguration operation from the data source selected by MSEL and is awaiting a response.
6	The PR IP has received the mailbox response from the SDM on the partial reconfiguration operation from the data source selected by MSEL.
7	Reserved.

2.3. Partial Reconfiguration Controller Intel Arria® 10/Cyclone® 10 FPGA IP

The Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP provides a standard interface to the partial reconfiguration functionality in the PR control block. Use this IP core to avoid manually instantiating a PR control block interface. The Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP supports Arria 10 and Cyclone 10 GX PR designs with a maximum clock frequency of 100MHz.

Figure 61. Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP



2.3.1. Agent Interface

The Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP provides an Avalon memory-mapped agent interface to read and write to PR configuration registers.

Table 19. Data/CSR Memory Map Format

Name	Address Offset	Access	Description
PR_DATA	0x00	Write	Every data `write` to this address indicates this bitstream is sent to the IP core. Performing a `read` on this address returns all 0's.
PR_CSR	0x01	Read or Write	Control and status registers.
`Version Register`	0x02	Read-Only	Read-only SW version register. Register is currently 0xAA500003
PR Bitstream ID	0x03	Read-Only	Read-only PR POF ID register

Table 20. PR_CSR Control and Status Bits

Bit Offset	Description
0	Read and write control register for `pr_start` signal. Refer to Ports on page 95 for details on the `pr_start` signal. `pr_start = PR_CSR[0]` The IP core deasserts `PR_CSR[0]` to value 0 automatically, one clock cycle after the `PR_CSR[0]` asserts. This streamlines the flow to avoid manual assertion and de-assertion of this register to control `pr_start` signal.
1	Reserved.
2-4	Read-only status register for `status[2:0]` signal. `PR_CSR[4:2] = status[2:0]` Refer to Ports on page 95 for details on the status signals.
5	Read and clear bit for interrupt. If you enable the interrupt interface, reading this bit returns the value of the `irq` signal. Writing a 1 clears the interrupt. If you disable the interrupt interface, reading this bit always returns a value of 0.
6-31	Reserved bits. Depends on the Avalon memory-mapped data bus width.

2.3.2. Reconfiguration Sequence

Partial reconfiguration occurs through the Avalon memory-mapped agent interface in the following sequence:

1. Avalon memory-mapped host component writes `0x01` to IP address offset 0x1 to trigger PR operation.
2. Optionally poll the status register until PR `Operation in Progress`. Not polling results in `waitrequest` on first word.
3. Avalon memory-mapped host component writes PR bitstream to IP address offset 0x0, until all the PR bitstream writes complete. When enhanced decompression is on, `waitrequest` activates throughout the PR operation. Ensure that your host can handle `waitrequest` from the agent interface.
4. Avalon memory-mapped host component reads the data from IP address offset 0x1 to check the `status[2:0]` value. Optionally, the Avalon memory-mapped host component reads the `status[2:0]` of this IP during a PR operation to detect any early failure, for example, PR_ERROR.

2.3.3. Interrupt Interface

If you enable the Avalon Memory Mapped agent interface, you can use the optional interrupt interface of the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP.

The IP core asserts `irq` during the following events:

Table 21. Interrupt Interface Events

Status Code	Event
3'b001	PR_ERROR occurred.
3'b010	CRC_ERROR occurred.
3'b011	The IP core detects an incompatible bitstream.
3'b101	The result of a successful PR operation.

After `irq` asserts, the host performs one or more of the following:

- Query for the status of the PR IP core; `PR_CSR[4:2]`.
- Carry out some action, such as error reporting.
- Once the interrupt is serviced, clear the interrupt by writing a "1" to `PR_CSR[5]`.

2.3.4. Parameters

The Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP supports customization of the following parameters.

Table 22. Parameter Settings

Parameter	Value	Description
Use as partial reconfiguration internal host	On|Off	Enables the controller for use as an internal host. Enabling this option auto-instantiates `prblock` and `crcblock` WYSIWYG as part of your design. Disable this option to use the controller as an external host. Connect additional interface signals to the dedicated partial reconfiguration pins.
Enable JTAG debug mode	On|Off	Enables access to the controller by the Quartus Prime Programmer for partial reconfiguration over a JTAG interface.
Enable Avalon-MM slave interface	On|Off	Enables the controller's Avalon memory-mapped agent interface. When this setting is Off, the IP controller enables the conduit interface.
Enable interrupt interface	On|Off	Enables interrupt assertion for detection of incompatible bitstream, `CRC_ERROR`, `PR_ERROR`, or successful partial reconfiguration. Upon interrupt, query `PR_CSR[4:2]` for status. Write a `1` to `PR_CSR[5]` to clear the interrupt. Use only together with the Avalon memory-mapped agent interface.
Enable freeze interface	On|Off	Enables the controller's single-bit freeze interface. This interface identifies whether any region in the design is active or frozen for partial reconfiguration operations. Leave this interface off, and use the freeze interface from the Partial Reconfiguration Region Controller IP instead.
Enable bitstream compatibility check	On|Off	Enables bitstream compatibility checks during partial reconfiguration operation from the external host. Bitstream compatibility check automatically enables when you use partial reconfiguration by internal host. Specify the partial reconfiguration bitstream ID value if you enable this option for partial reconfiguration by external host.

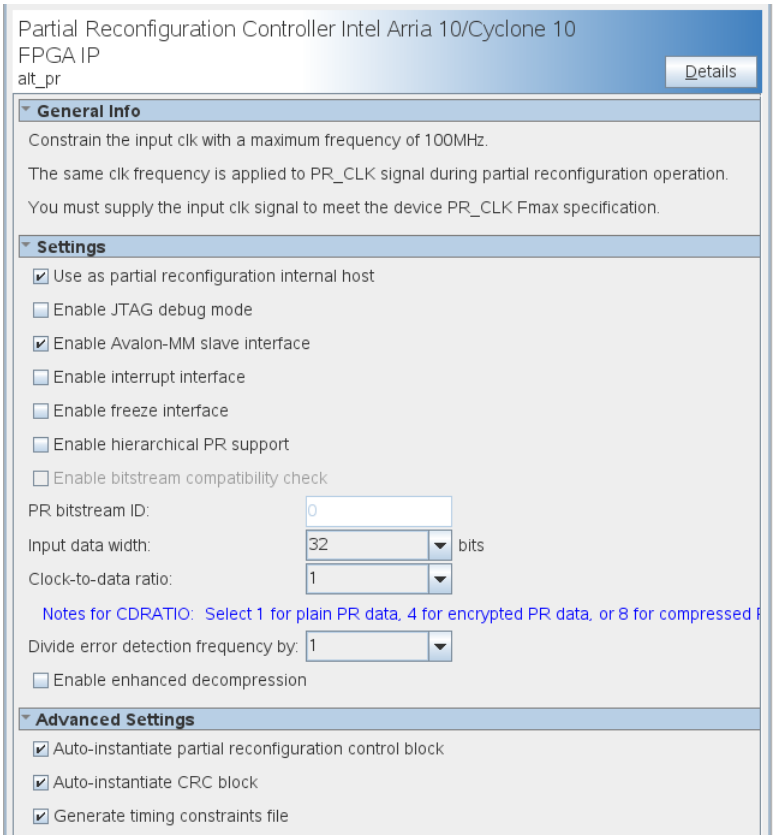
continued...

Parameter	Value	Description
PR bitstream ID	*<32-bit integer>*	Specifies a signed, 32-bit integer value of the partial reconfiguration bitstream ID for the external host. This value must match the partial reconfiguration bitstream ID that the Compiler generates for the target partial reconfiguration design. Locate the partial reconfiguration bitstream ID of the target partial reconfiguration design in the Assembler report (`.asm.rpt`).
Input data width	`1|8|16|32`	Specifies the size of the controller's data conduit interface in bits. Refer to Error Detection CRC Requirements on page 94.
Clock-to-data ratio	`1|4|8`	Specifies the clock-to-data ratio that corresponds with the partial reconfiguration bitstream data type. Refer to the Valid combinations and CD Ratio for Bitstream Encryption and Compression Table.
Divide error detection frequency by	`1..256`	Specifies the divide value of the internal clock. This value determines the frequency of the error detection CRC. The divide value must be a power of two. Refer to device documentation to determine the frequency of the internal clock for the device you select. Refer to Error Detection CRC Requirements on page 94.
Enable enhanced decompression	On|Off	Enable enhanced decompression of partial reconfiguration bitstreams. *Note:* You cannot use enhanced decompression together with encryption simultaneously. Enhanced decompression is only available with the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP.

Table 23. Advanced Settings

Parameter	Value	Description
Auto-instantiate partial reconfiguration control block	On|Off	Automatically includes the partial reconfiguration control block in the controller. When using the controller as an internal host, disable this option to share the partial reconfiguration block with other IP cores. Rather, manually instantiate the partial reconfiguration control block, and connect the relevant signals to the controller.
Auto-instantiate CRC block	On|Off	Automatically includes the CRC block within the controller. Leave this option enabled unless you plan to use single event upset (SEU) IP in the same PR design. If you disable this option, IP generation exports the `crc_error_pin` for manual connection to an external CRC block that you manually instantiate. If you disable this option and then subsequently leave the exported `crc_error_pin` floating, the PR operation is undetermined due to unexpected `crc_error_pin`.
Generate timing constraints file	On|Off	Automatically generates an appropriate Synopsys Design Constraints (`.sdc`) file to constrain the timing of the controller. Disable this option when providing timing constraints in another file.

Figure 62. Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP Parameter Editor



2.3.4.1. Error Detection CRC Requirements

The following describes requirements for enabling the error detection CRC option with various PR configuration method and parameter combinations. Click **Assignments ➤ Device ➤ Device & Pin Options ➤ Error Detection CRC ➤ Enable Error Detection Check** to enable EDCRC prior to PR bitstream generation.

Note: When using the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP with a 32-bit **Input data width**, and with Passive Parallel x1, x8, or x16 configuration, you must turn on the **Enable Error Detection Check** option, and specify a **Divide error detection frequency by** value of 2 or 4.

Note: When using the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP with a 32-bit **Input data width** and Passive Parallel x32 configuration, PR supports **Enable Error Detection Check** on or off. If **Enable Error Detection Check** is on, PR supports all values for **Divide error detection frequency by**.

Note: When using the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP with 1, 8, or 16-bit **Input data width**, and with Passive Parallel x1, x8, x16, or x32 configuration, PR supports **Enable Error Detection Check** turned on or off. If **Enable Error Detection Check** is on, PR supports all values for **Divide error detection frequency by**.

Table 24. Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP Error Detection CRC (EDCRC) Requirements Summary

PR IP Input Data Width	Configuration Mode	Enable Error Detection Check	PR Support
1, 8, 16	Passive Parallel x1, x8, x16	Off	Yes
1, 8, 16	Passive Parallel x1, x8, x16	On	Yes, for all **Divide error detection frequency by** values
32	Passive Parallel x1, x8, x16	Off	No support
32	Passive Parallel x1, x8, x16	On	Yes, for only **Divide error detection frequency by** value 2 or 4
1, 8, 16, 32	Passive Parallel x32	Off	Yes
1, 8, 16, 32	Passive Parallel x32	On	Yes, for all **Divide error detection frequency by** values

2.3.5. Ports

The Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP includes the following interface ports.

Figure 63. Partial Reconfiguration Controller Interface Ports (Internal Host)

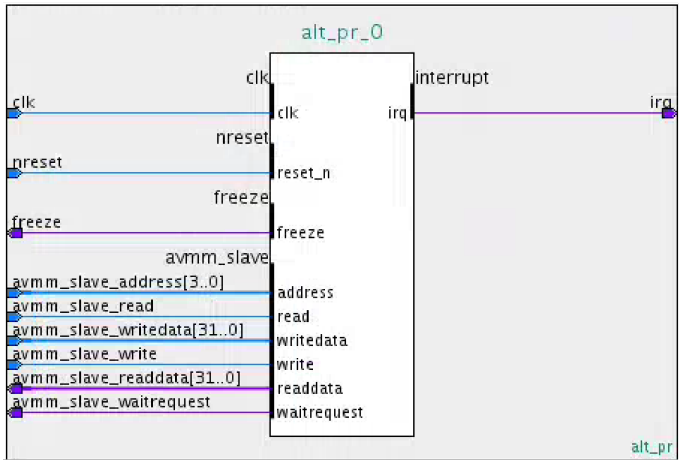


Figure 64. Partial Reconfiguration Controller Interface Ports (External Host)

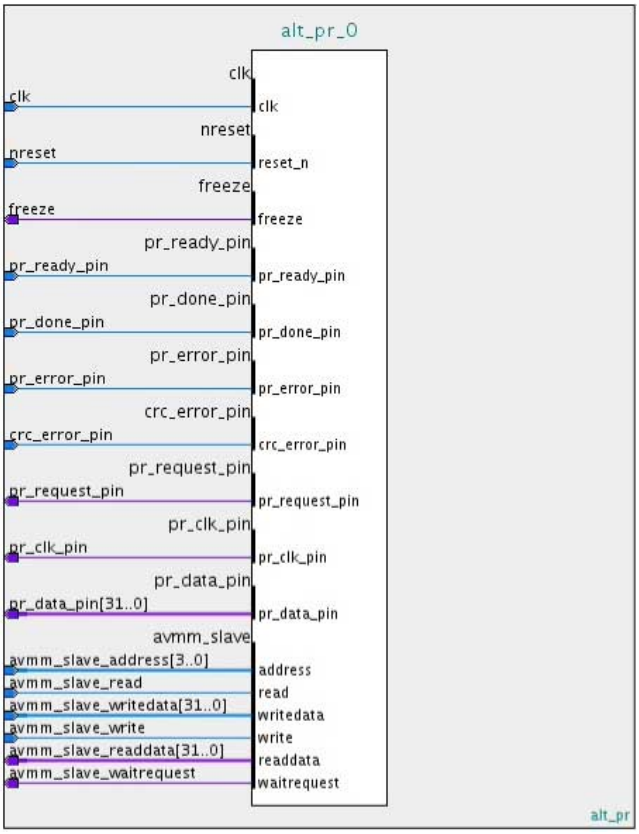

Table 25. Clock/Reset Ports

Port Name	Width	Direction	Function
`nreset`	1	Input	Asynchronous reset for the PR Controller IP core. Resetting the PR Controller IP core during a partial reconfiguration operation initiates the withdrawal sequence.
`clk`	1	Input	User input clock to the PR Controller IP core. The IP core has a maximum clock frequency of 100MHz. The IP core ignores this signal during JTAG debug operations.

Table 26. Freeze Interface Port

Port Name	Width	Direction	Function
`freeze`	1	Output	Active high signal that freezes the PR interface signals of any region undergoing partial reconfiguration. De-assertion of this signal indicates the end of PR operation. Use the Partial Reconfiguration Region Controller IP for this operation rather than the Partial Reconfiguration Controller IP `freeze` signal.

Table 27. Conduit Interface Ports

These ports are available when **Enable Avalon Memory-Mapped agent interface** is **Off**.

Port Name	Width	Direction	Function
pr_start	1	Input	A 0 to 1 transition on this port initiates a PR event. You must assert this signal high for a minimum of one clock cycle, and de-assert the signal low prior to the end of the PR operation. This operation ensures the PR Controller IP core is ready to accept the next pr_start trigger event when the freeze signal is low. The PR Controller IP core ignores this signal during JTAG debug operations.
data[]	1, 8, 16, or 32	Input	Selectable input PR data bus width, either x1, x8, x16, or x32. Once a PR event triggers, the PR event is synchronous with the rising edge of the clk signal, whenever the data_valid signal is high, and the data_ready signal is high. The PR Controller IP core ignores this signal during JTAG debug operations.
data_valid	1	Input	A 0 to 1 transition on this port indicates the data[] port contains valid data. The PR Controller IP core ignores this signal during JTAG debug operations.
data_ready	1	Output	A 0 to 1 transition on this port indicates the PR Controller IP core is ready to read the valid data on the data[] port, whenever the data_valid signal asserts high. The data sender must stop sending valid data if this port is low. This signal deasserts low during JTAG debug operations.
status[2:0]	1	Output	A 3-bit output that indicates the status of PR events. When the IP detects an error (PR_ERROR, CRC_ERROR, or incompatible bitstream error), this signal latches high. This signal only resets at the beginning of the next PR event, when pr_start is high, and freeze is low. For example: 3'b000 – power-up or nreset asserts 3'b001 – PR_ERROR triggers 3'b010 – CRC_ERROR triggers 3'b011 – Incompatible bitstream error detection 3'b100 – PR operation in progress 3'b101 – PR operation passes 3'b110 – Reserved bit 3'b111 – Reserved bit

Table 28. Avalon Memory-Mapped Slave Interface Ports

These signals are available when **Enable Avalon memory-mapped slave interface** is **On**.

Port Name	Width	Direction	Function
avmm_slave_address	4	Input	Avalon memory-mapped address bus. The address bus is in the unit of Word addressing. The PR Controller IP core ignores this signal during JTAG debug operations.
avmm_slave_read	1	Input	Avalon memory-mapped read control. The PR Controller IP core ignores this signal during JTAG debug operations.

continued...

Port Name	Width	Direction	Function
avmm_slave_readdata	32	Output	Avalon memory-mapped read data bus. The PR Controller IP core ignores this signal during JTAG debug operations.
avmm_slave_write	1	Input	Avalon memory-mapped write control. The PR Controller IP core ignores this signal during JTAG debug operations.
avmm_slave_writedata	32	Input	Avalon memory-mapped write data bus. The PR Controller IP core ignores this signal during JTAG debug operations.
avmm_slave_waitrequest	1	Output	Indicates that the IP is busy. Also indicates that the IP core is unable to respond to a read or write request. The IP core pulls this signal high during JTAG debug operations.

Table 29. Interrupt Interface Ports

These ports are available when **Enable interrupt interface** is **On**.

Port Name	Width	Direction	Function
irq	1	Output	The interrupt signal.

Table 30. CRC BLOCK Interface

These ports are available when **Use as Partial Reconfiguration Internal Host** is **Off**, or when you instantiate the CRCBLOCK manually for an internal host.

Port Name	Width	Direction	Function
crc_error_pin	1	Input	Available when you use the PR Controller IP core as an External Host. Connect this port to the dedicated CRC_ERROR pin of the FPGA undergoing partial reconfiguration.

Table 31. PR Block Interface

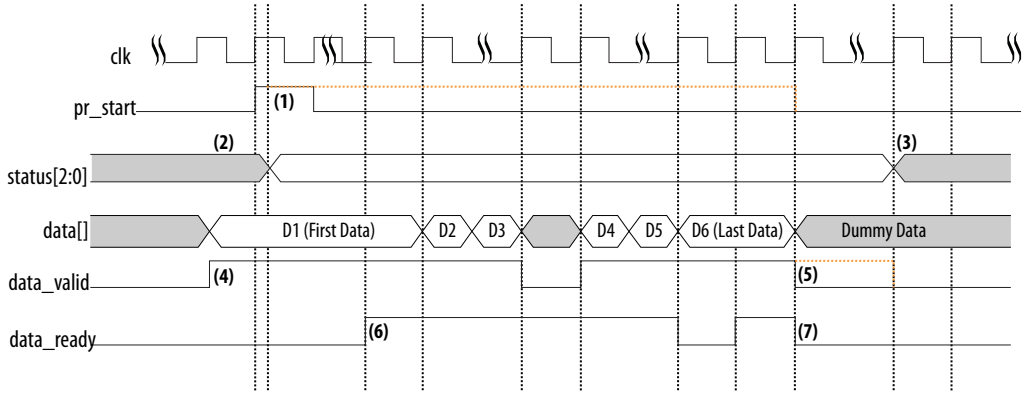
These options are available when **Use as Partial Reconfiguration Internal Host** is **Off**, or when you instantiate the PRBLOCK manually for an internal host.

Port Name	Width	Direction	Function
pr_ready_pin	1	Input	Connect this port to the dedicated PR_READY pin of the FPGA undergoing partial reconfiguration.
pr_error_pin	1	Input	Connect this port to the dedicated PR_ERROR pin of the FPGA undergoing partial reconfiguration.
pr_done_pin	1	Input	Connect this port to the dedicated PR_DONE pin of the FPGA undergoing partial reconfiguration.
pr_request_pin	1	Output	Connect this port to the dedicated PR_REQUEST pin of the FPGA undergoing partial reconfiguration.
pr_clk_pin	1	Output	Connect this port to the dedicated DCLK of the FPGA undergoing partial reconfiguration.
pr_data_pin[31..0]	16|32	Output	Connect this port to the dedicated DATA[31..0] pins of the FPGA undergoing partial reconfiguration.

2.3.6. Timing Specifications

The following timing diagram illustrates a successful PR operation with Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP. The `status[2:0]` output signal indicates whether the operations passes or fails. The PR operation initiates upon assertion of the `pr_start` signal. Monitor the `status[]` signal to detect the end of the PR operation.

Figure 65. Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP Timing Specifications



The following notes correspond to locations (1) through (7) in the timing diagram:

1. Assert `pr_start` signal high for a minimum of one clock cycle to initiate PR. Deassert `pr_start` before sending the last data.
2. `status[]` signal updates after `pr_start` is acknowledged. This signal changes during a PR operation if CRC_ERROR, PR_ERROR, or bitstream incompatibility error occurs.
3. `status[]` signal changes after a PR operation if CRC_ERROR asserts and no error occurs during the previous PR operation.
4. There is no requirement to assert the `data_valid` signal at the same time as the `pr_start` signal. Provide the `data[]`, and assert `data_valid`, when appropriate.
5. Either drive the `data_valid` signal low after sending the last data, or continue to assert `data_valid` high with dummy data on `data[]` until the IP reads the end of PR from `status[]`.
6. `data[]` transfers only when `data_valid` and `data_ready` assert on the same cycle. Do not drive new data on the data bus, when both `data_valid` and `data_ready` are not high.
7. The `data_ready` signal drives low after the PR IP Controller core receives the last data, or when the PR IP Controller cannot accept data.

2.3.7. PR Control Block and CRC Block Verilog HDL Manual Instantiation

The Partial Reconfiguration Controller Arria 10/Cyclone 10 IP includes the PR control block. However, if you create your own custom logic to perform the function of the IP core, you can manually instantiate the control block to communicate with the FPGA system.

The following example instantiates a PR control block inside a top-level Arria 10 PR project, `Chip_Top`, in Verilog HDL:

```
Chip_Top:
module Chip_Top (
 //User I/O signals (excluding PR related signals)
..
..
//PR interface and configuration signals declaration
 wire pr_request;
 wire pr_ready;
 wire pr_done;
 wire crc_error;
 wire dclk;
 wire [31:0] pr_data;

twentynm_prblock m_pr
 (
 .clk (dclk),
 .corectl (1'b1),
 .prrequest(pr_request),
 .data (pr_data),
 .error (pr_error),
 .ready (pr_ready),
 .done (pr_done)
 );

twentynm_crcblock m_crc
 (
 .clk (clk),
 .shiftnld (1'b1),
 .crcerror (crc_error)
 );
endmodule
```

For more information about port connectivity for reading the Error Message Register (EMR), refer to the *AN539: Test Methodology of Error Detection and Recovery using CRC*.

Related Information

AN539: Test Methodology of Error Detection and Recovery using CRC in Intel FPGA Devices

2.3.8. PR Control Block and CRC Block VHDL Manual Instantiation

The following example shows manual instantiation of a PR control block inside your top-level Arria 10 project, `Chip_Top`, in VHDL:

```
module Chip_Top is port (
 --User I/O signals (excluding signals that relate to PR)
 ..
 ..
 )
-- Following shows the connectivity within the Chip_Top module
Core_Top : Core_Top
```

```
 port_map (
 ..
 ..
 );
m_pr : twentynm_prblock
 port map(
clk => dclk,
 corectl =>'1', --1 - when using PR from inside
 --0 - for PR from pins; You must also enable
 -- the appropriate option in Quartus Prime settings
 prrequest => pr_request,
 data => pr_data,
 error => pr_error,
 ready => pr_ready,
 done => pr_done
 );
m_crc : twentynm_crcblock
 port map(
 shiftnld => '1', --If you want to read the EMR register when
 clk => dummy_clk, --error occurrs, refer to AN539 for the
 --connectivity for this signal. If you only want
 --to detect CRC errors, but plan to take no
 --further action, you can tie the shiftnld
 --signal to logical high.
 crcerror => crc_error
 );
```

Note: You are not required to connect a real clock source to `dummy_clk`, but you must connect `dummy_clk` to an I/O pin to avoid removal of this signal.

2.3.8.1. PR Control Block and CRC Block VHDL Component Declaration

The following example shows manual instantiation of the PR control block and the CRC block in your Arria 10 PR design:

1. Use the code sample below, containing the component declaration in VHDL. This code performs the PR function from within the core (code block within `Core_Top`).

```
module Chip_Top is port (
    --User I/O signals (excluding signals that relate to PR)
    ..
    ..
)
-- Following shows the connectivity within the Chip_Top module
Core_Top : Core_Top
port_map (
    ..
    ..
);

m_pr : twentynm_prblock
port map(
    clk => dclk,
    corectl =>'1', --1 - when using PR from inside
    --0 - for PR from pins; You must also enable
    -- the appropriate option in Quartus Prime settings
    prrequest => pr_request,
    data => pr_data,
    error => pr_error,
    ready => pr_ready,
    done => pr_done
);

m_crc : twentynm_crcblock
port map(
    shiftnld => '1', --If you want to read the EMR register when
    clk => dummy_clk, --error occurrs, refer to AN539 for the
    --connectivity forthis signal. If you only want
```

```
    --to detect CRC errors, but plan to take no
    --further action, you can tie the shiftnld
    --signal to logical high.
    crcerror => crc_error
);
```

Note: This VHDL example is adaptable for Verilog HDL instantiation.

2. Add additional ports to `Core_Top` to connect to both components.
3. Follow these rules when connecting the PR control block to the rest of your design:
   - Set the `corectl` signal to '1' (when using partial reconfiguration from core) or to '0' (when using partial reconfiguration from pins).
   - The `corectl` signal must match the **Enable PR pins** option setting in the **Device and Pin Options** dialog box (**Assignments ➤ Device ➤ Device and Pin Options**).
   - When performing partial reconfiguration from pins, the Fitter automatically assigns the PR unassigned pins. Assign all the dedicated PR pins using Pin Planner (**Assignments ➤ Pin Planner**) or Assignment Editor (**Assignments ➤ Assignment Editor**).
   - When performing partial reconfiguration from the core logic, connect the `prblock` signals to either core logic or I/O pins, excluding the dedicated programming pin, such as DCLK.

2.3.9. PR Control Block Signals

The following table lists the partial reconfiguration control block interface signals for the Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP:

Table 32. PR Control Block Interface Signals

Signal	Width	Direction	Description
pr_data	[31:0]	Input	Carries the configuration bitstream.
pr_done	1	Output	Indicates that the PR process is complete.
pr_ready	1	Output	Indicates that the control block is ready to accept PR data from the control logic.
pr_error	1	Output	Indicates a partial reconfiguration error.
pr_request	1	Input	Indicates that the PR process is ready to begin.
corectl	1	Input	Determines whether you are performing the partial reconfiguration internally, or through pins.

Note:

- You can specify a configuration width of 8, 16, or 32 bits, but the interface always uses 32 pins.
- All the inputs and outputs are asynchronous to the PR clock (`clk`), except `data` signal. `data` signal is synchronous to `clk` signal.
- PR clock must be free-running.
- `data` signal must be 0 while waiting for `ready` signal.

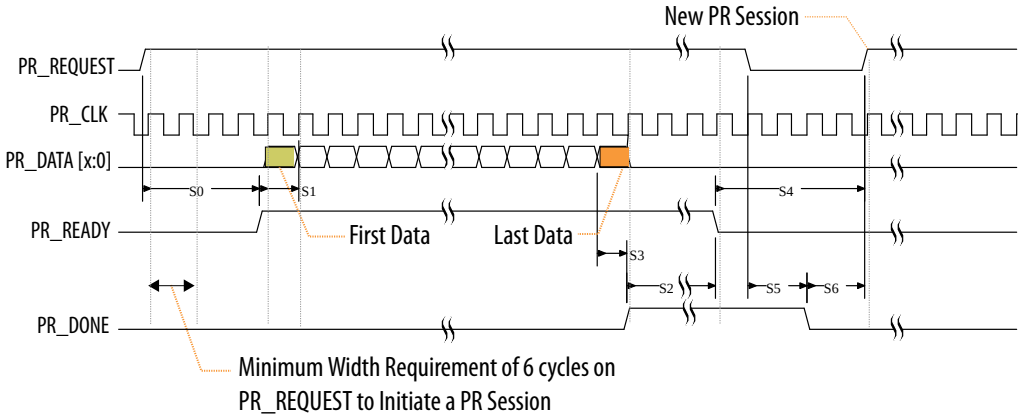
2.3.9.1. PR Control Block Signal Timing Diagrams

2.3.9.1.1. Successful PR Session (Arria 10 Example)

The following flow describes a successful Arria 10 PR session:

1. Assert PR_REQUEST and wait for PR_READY; drive PR_DATA to 0.
2. The PR control block asserts PR_READY, asynchronous to `clk`.
3. Start sending Raw Binary File (`.rbf`) to the PR control block, with 1 valid word per clock cycle. On `.rbf` file transfer completion, drive PR_DATA to 0. The PR control block asynchronously asserts PR_DONE when the control block completes the reconfiguration operation. The PR control block deasserts PR_READY on configuration completion.
4. Deassert PR_REQUEST. The PR control block acknowledges the end of PR_REQUEST, and deasserts PR_DONE. The host can now initiate another PR session.

Figure 66. Timing Diagram for Successful Arria 10 PR Session



Related Information

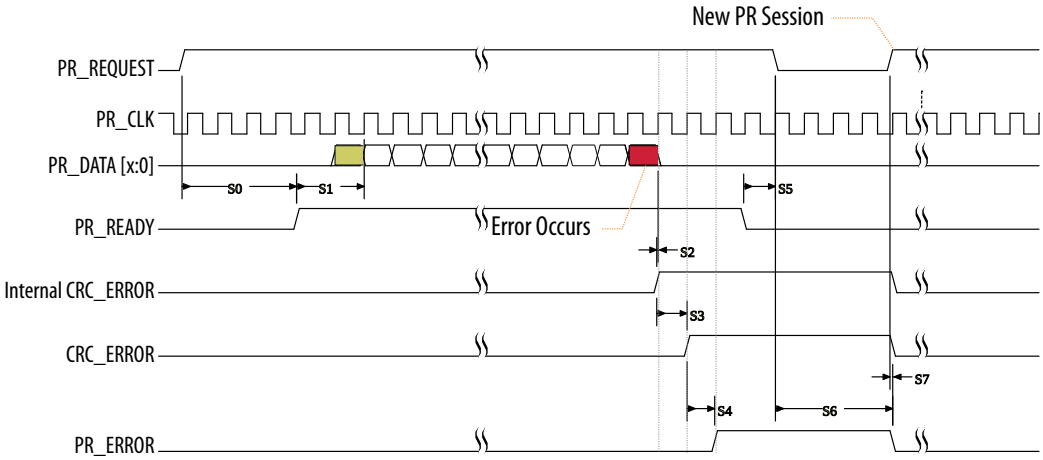
Raw Binary Programming File Byte Sequence Transmission Examples on page 33

2.3.9.1.2. Unsuccessful PR Session with Configuration Frame Readback Error (Arria 10 Example)

The following flow describes an Arria 10 PR session with error in the EDCRC verification of a configuration frame readback:

1. The PR control block internally detects a CRC error.
2. The CRC control block then asserts CRC_ERROR.
3. The PR control block asserts the PR_ERROR.
4. The PR control block deasserts PR_READY, so that the host can withdraw the PR_REQUEST.
5. The PR control block deasserts CRC_ERROR and clears the internal CRC_ERROR signal to get ready for a new PR session. The host can now initiate another PR session.

Figure 67. Timing Diagram for Unsuccessful Arria 10 PR Session with Configuration Frame Readback Error

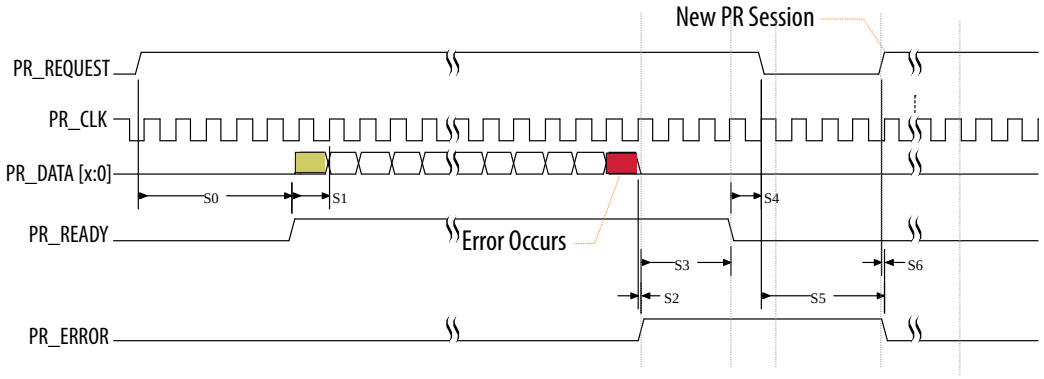


2.3.9.1.3. Unsuccessful PR Session with PR_ERROR (Arria 10 Example)

The following flow describes an Arria 10 PR session with transmission error or configuration CRC error:

1. The PR control block asserts PR_ERROR.
2. The PR control block deasserts PR_READY, so that the host can withdraw PR_REQUEST.
3. The PR control block deasserts PR_ERROR to get ready for a new PR session. The host can now initiate another PR session.

Figure 68. Timing Diagram for Unsuccessful Arria 10 PR Session with PR_ERROR

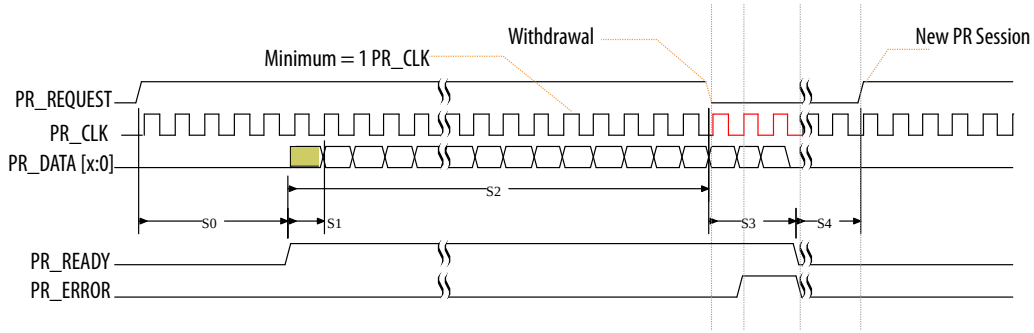


2.3.9.1.4. Late Withdrawal PR Session (Arria 10 Example)

The following flow describes a late withdrawal Arria 10 PR session:

1. The PR host can withdraw the request after the PR control block asserts PR_READY.
2. The PR control block deasserts PR_READY. The host can now initiate another PR session.

Figure 69. Timing Diagram for Late Withdrawal Arria 10 PR Session



Note: The PR host can withdraw the request any time before the PR controller asserts PR_READY. Therefore, the PR host must not return until the PR control block asserts PR_READY. Provide at least 10 PR_CLK cycles after deassertion of PR_REQUEST, before requesting a new PR session.

2.3.10. Configuring an External Host for Arria 10 or Cyclone 10 GX Designs

When using external host configuration, the external host initiates partial reconfiguration, and monitors the PR status using the external PR dedicated pins during user mode. In this mode, the external host must respond appropriately to the handshake signals for successful partial reconfiguration. The external host writes the partial bitstream data from external memory into the Arria 10 or Cyclone 10 GX device. Co-ordinate system-level partial reconfiguration by ensuring that you prepare the correct PR region for partial reconfiguration. After reconfiguration, return the PR region into operating state.

To use an external host for your design:

1. Click **Assignments ➤ Device ➤ Device & Pin Options**.
2. Select the **Enable PR Pins** option in the **Device & Pin Options** dialog box. This option automatically creates the special partial reconfiguration pins, and defines the pins in the device pin-out. This option also automatically connects the pins to PR control block internal path.

   Note: If you do not select this option, you must use an internal or HPS host. You do not need to define pins in your design top-level entity.
3. Connect these top-level pins to the specific ports in the PR control block.

The following table lists the PR pins that automatically constrain when you turn on **Enable PR Pins**, and the specific PR control block port connection to the pin:

Table 33. Partial Reconfiguration Dedicated Pins

Pin Name	Type	PR Control Block Port Name	Description
PR_REQUEST	Input	prrequest	Logic high on this pin indicates that the PR host is requesting partial reconfiguration.
PR_READY	Output	ready	Logic high on this pin indicates that the PR control block is ready to begin partial reconfiguration.
PR_DONE	Output	done	Logic high on this pin indicates that the partial reconfiguration is complete.
PR_ERROR	Output	error	Logic high on this pin indicates an error in the device during partial reconfiguration.
DATA[31:0]	Input	data	These pins provide connectivity for PR_DATA to transfer the PR bitstream to the PR controller.
DCLK	Input	clk	Receives synchronous PR_DATA.

Note:

1. PR_DATA can be 8, 16, or 32-bits in width.
2. Ensure that you connect the `corectl` port of the PR control block to 0.

Example 4. Verilog RTL for External Host PR

```
module top(
     // PR control block signals
     input  logic        pr_clk,
     input  logic        pr_request,
     input  logic [31:0] pr_data,
     output logic        pr_error,
     output logic        pr_ready,
     output logic        pr_done,

     // User signals
     input  logic i1_main,
     input  logic i2_main,
     output logic o1
```

```
);

// Instantiate the PR control block
twentynm_prblock m_prblock
(
    .clk(pr_clk),
    .corectl(1'b0),
    .prrequest(pr_request),
    .data(pr_data),
    .error(pr_error),
    .ready(pr_ready),
    .done(pr_done)
);

// PR Interface partition
pr_v1 pr_inst(
   .i1(i1_main),
   .i2(i2_main),
   .o1(o1)
);

endmodule
```

Example 5. VHDL RTL for External Host PR

```

```

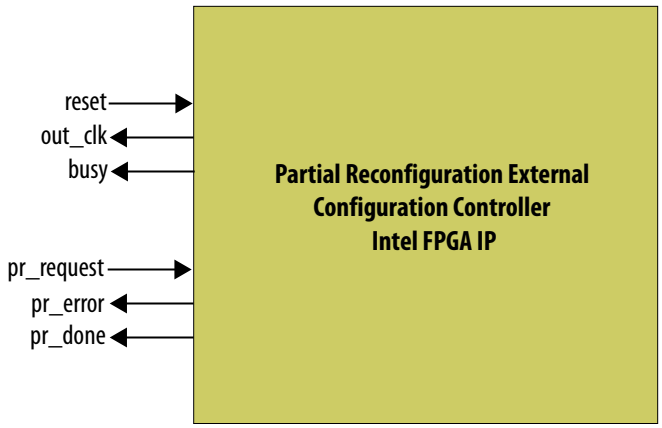
2.4. Partial Reconfiguration External Configuration Controller Intel FPGA IP

The Partial Reconfiguration External Configuration Controller Intel FPGA IP supports partial reconfiguration via an external source.

When using external configuration, you must connect all the top-level ports of the Partial Reconfiguration External Configuration Controller Intel FPGA IP to the `pr_request` and `status` pins. These connections allow the handshaking of the host with the SDM from the Agilex 7, Agilex 5, or Stratix 10 device core. The SDM determines which types of configuration pins to use, according your MSEL setting.

Figure 70. Partial Reconfiguration External Configuration Controller Intel FPGA IP



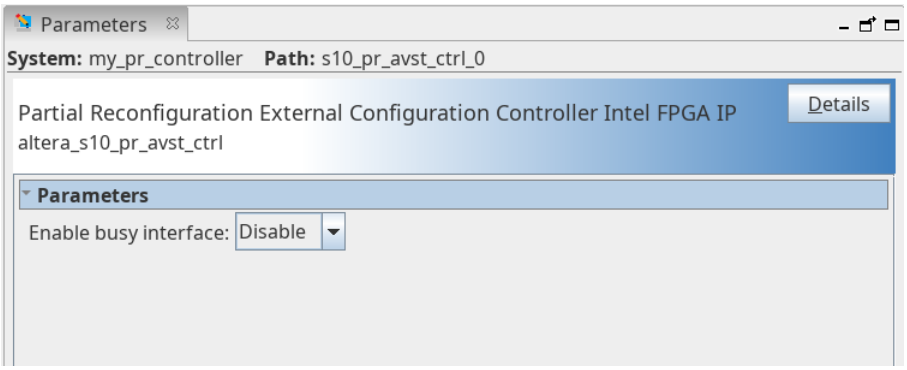
2.4.1. Parameters

The Partial Reconfiguration External Configuration Controller Intel FPGA IP supports customization of the following parameters.

Table 34. Partial Reconfiguration External Configuration Controller Parameter Settings

Parameter	Value	Description
Enable Busy Interface	**On/Off**	Allows you to Enable or Disable the Busy interface, which asserts a signal to indicate that PR processing is in progress during external configuration. Default setting is **Off**.

Figure 71. Parameter Editor



2.4.2. Ports

The Partial Reconfiguration External Configuration Controller Intel FPGA IP includes the following interface ports.

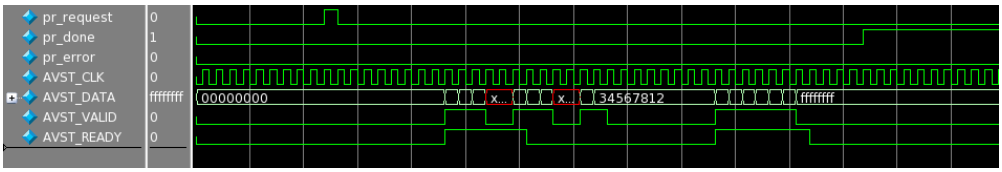
Table 35. Ports

Port Name	Width	Direction	Function
`pr_request`	1	Input	Indicates that the PR process is ready to begin. The signal is a conduit not synchronous to any clock signal.
`pr_error`	2	Output	Indicates a partial reconfiguration error.: • `2'b01`—general PR error • `2'b11`—incompatible bitstream error These signals are conduits not synchronous to any clock source.
`pr_done`	1	Output	Indicates that the PR process is complete. The signal is a conduit not synchronous to any clock signal.
`start_addr`	1	Input	Specifies the start address of PR data in Active Serial Flash. You enable this signal by selecting either **Avalon-ST** or **Active Serial** for the **Enable Avalon-ST Pins or Active Serial Pins** parameter. The signal is a conduit not synchronous to any clock signal.
`reset`	1	Input	Active high, synchronous reset signal.
`out_clock`	1	Output	Clock source that generates from an internal oscillator.
`busy`	1	Output	The IP asserts this signal to indicate PR data transfer in progress. You enable this signal by selecting **Enable** for the **Enable busy interface** parameter.

2.4.3. Partial Reconfiguration External Controller Intel FPGA IP Timing Specifications

Timing Specifications: Partial Reconfiguration External Controller Intel FPGA IP illustrates a successful PR operation with the Partial Reconfiguration External Controller Intel FPGA IP. The PR operation initiates upon assertion of the `pr_request` signal. The `avst_ready` output signal indicates whether the SDM is ready to accept data from an external host.

Figure 72. Timing Specifications: Partial Reconfiguration External Controller Intel FPGA IP



2.4.4. Configuring an External Host for Agilex 7, Agilex 5, and Stratix 10 Designs

You can optionally use an external host to write the partial bitstream data from external memory into the Agilex 7, Agilex 5, or Stratix 10 device. When using external host configuration, the external host initiates partial reconfiguration by asserting the `pr_request` signal. The external host monitors the PR status through the `pr_done` and `pr_error` signals.

The external host must respond appropriately to the handshake signals for successful partial reconfiguration. Co-ordinate system-level partial reconfiguration by ensuring that you prepare the correct PR region for partial reconfiguration. After reconfiguration, return the PR region into operating state.

To configure an external host, follow these steps:

1. Parameterize and generate the Partial Reconfiguration External Configuration Controller Intel FPGA IP, as Specifying the IP Core Parameters and Options (Quartus Prime Pro Edition) on page 133 describes.
2. Connect the Partial Reconfiguration External Configuration Controller `pr_request`, `pr_done`, and `pr_error` signals to top-level pins for control and monitor by the external host. You can assign the pin location by clicking **Assignments ➤ Pin Planner**.
3. Click **Assignments ➤ Device**, and then click the **Device & Pin Options** button.
4. In the **Category** list, click **Configuration**.
5. For the **Configuration scheme**, select the scheme that matches with your full device configuration. For example, if your full device configuration uses the **AVSTx32** scheme, the PR configuration must use **AVSTx32**.This option automatically reserves dedicated Avalon streaming configuration pins for partial reconfiguration during user mode. The pins are exactly same as the Avalon streaming pins that you use for full device configuration.

The following table describes the PR pins that the external host uses. The PR streaming to Avalon streaming pins must conform to the Avalon streaming specification for data transfer with backpressure.

Table 36. Partial Reconfiguration External Configuration Pins

Pin Name	Type	Description
pr_request	Input	User-assigned port connected to Partial Reconfiguration External Configuration Controller IP. Logic high on this pin indicates that the PR host is requesting partial reconfiguration.
pr_done	Output	User-assigned port connected to Partial Reconfiguration External Configuration Controller IP. Logic high on this pin indicates that the partial reconfiguration is complete.
pr_error	Output	User-assigned port connected to Partial Reconfiguration External Configuration Controller IP. Logic high on this pin indicates an error in the device during partial reconfiguration.
avst_data: avstx8 - [7:0] avstx16 - [15:0] avstx32 - [31:0]	Input	These pins provide connectivity for the external host to transfer the PR bitstream to the SDM. The avstx8 data pins are part of the SDM I/O. avstx16 and avstx32 data pins are from I/O 48 bank 3A.
avst_clk	Input	Clocks the Avalon streaming interfaces. avst_data and avst_valid are synchronous with avst_clk. The avstx8 clk pin is part of the SDM I/O. avstx16 and avstx32 are from I/O 48 bank 3A.
avst_valid	Input	Logic high on this pin indicates the data in avst_data is valid data. The avstx8 data pins are part of the SDM I/O. avstx16 and avstx32 data pins are from I/O 48 bank 3A.
avst_ready	Output	Logic high on this pin indicates the SDM is ready to accept data from an external host. This output is part of the SDM I/O.

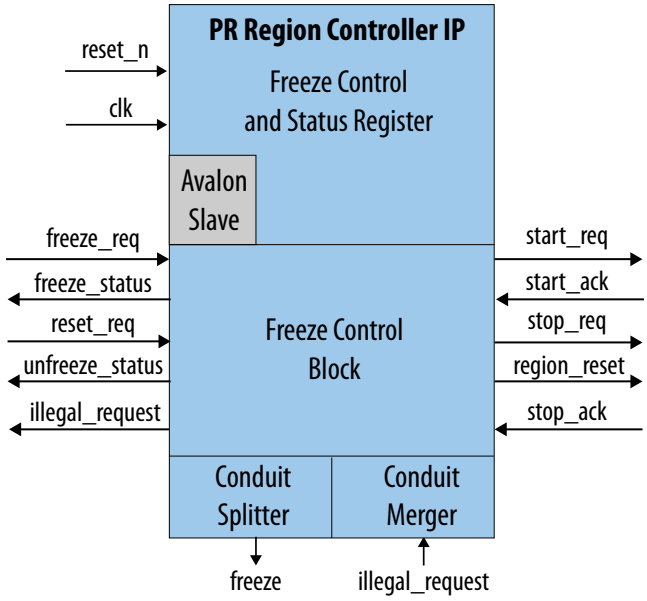
2.5. Partial Reconfiguration Region Controller Intel FPGA IP

The Partial Reconfiguration Region Controller Intel FPGA IP provides a standard interface through the Freeze Control block that controls handshaking with the PR region. The PR handshake ensures that PR region transactions complete before freeze of the interface.

Table 37. PR Region Controller Sections

IP Component	Description
Freeze Control and Status Register	Freeze status register that generates the freeze output signal.
Freeze Control Block	Performs PR handshaking and resets the PR region.
Conduit Splitter	Connects the controller's freeze signal to one or more Freeze Bridge components. Receives the freeze signal from the Freeze Control Block, and assigns the freeze input signal to one or more freeze output signals.
Conduit Merger	Connects the illegal_request signal from one or more Freeze Bridge components to the PR Region Controller. The illegal_request is a single-bit output signal from the Freeze Bridge. Conduit Merger concatenates the single-bit signal from multiple Freeze Bridges into a multi-bit bus. The Conduit Merger then connects the bus to the Freeze Control Block.

Figure 73. Partial Reconfiguration Region Controller IP Core



2.5.1. Registers

The Partial Reconfiguration Region Controller IP core performs the following operations in a partial reconfiguration:

Figure 74. Freeze Control Block PR Handshake Timing

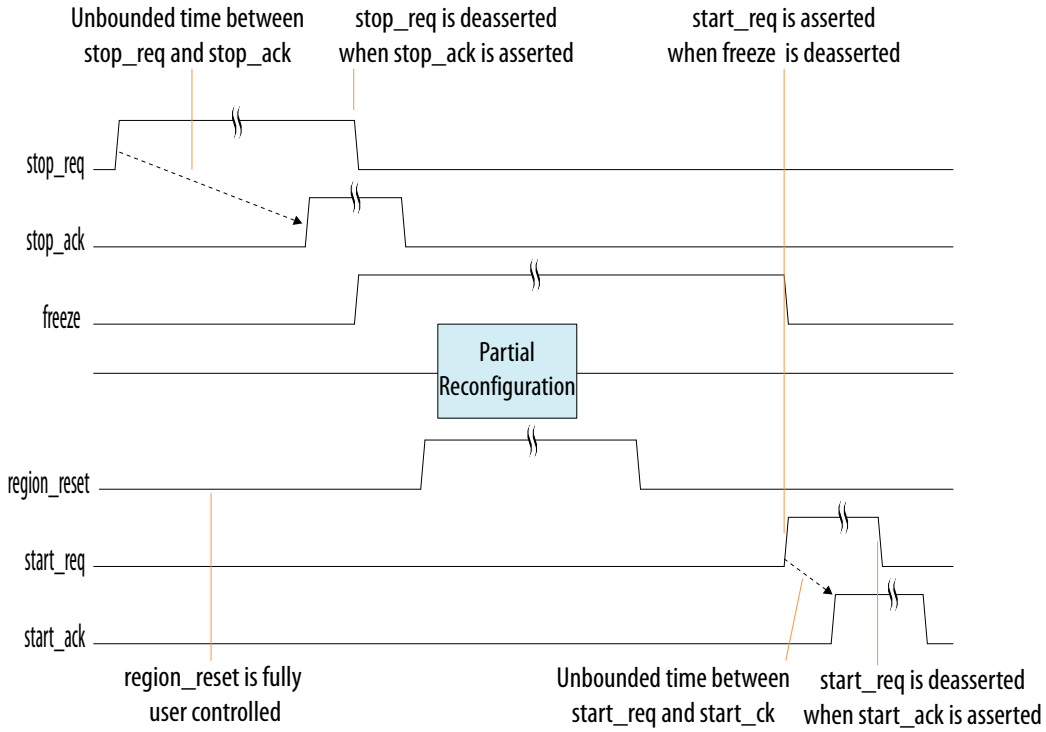


Figure 75. Register States and Programming Model

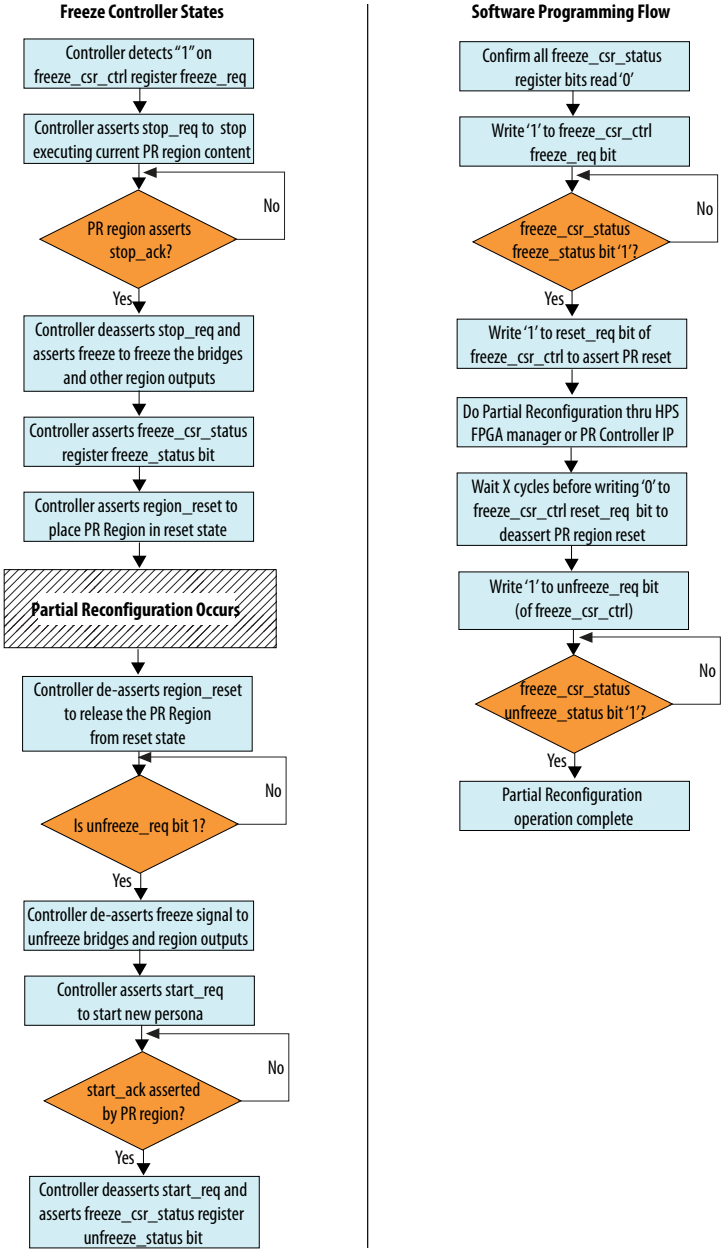

Table 38. Register Map

Name	Address Offset	Access	Description
freeze_csr_status	0x00	Read-Only	Freeze status register.
csr_ctrl	0x01	Read or Write	Control register to enable and disable freeze.
freeze_illegal_req	0x02	Read or Write	High on any bit indicates an illegal request during the freeze state.
freeze_reg_version	0x03	Read-Only	Read-only version register. This register is currently 0xAD000003.

Table 39. freeze_csr_status

Bit	Fields	Access	Default Value	Description
31:2	Reserved	N/A	0x0	Reserved bits. Reading these bits always returns zeros.
1	unfreeze_status	R	0	Hardware sets this bit to 1 after the PR region returns start_ack to indicate successful start of the persona. Hardware clears this bit to 0 when the unfreeze_req bit is low. This bit is 1 when bridges and other PR region outputs release from reset.
0	freeze_status	R	0	Hardware sets this bit to 1 after the PR region returns the stop_ack signal to indicate that the PR region is ready to enter the frozen state Hardware clears this bit to 0 when the freeze_req bit is low. This bit is 0 when bridges and other PR region outputs release from reset.

Table 40. freeze_csr_ctrl

Bit	Fields	Access	Default Value	Description
31:3	Reserved	N/A	0x0	Reserved bits. Reading these bits always returns zeros.
2	unfreeze_req	R/W	0	Write 1 to this bit to request unfreezing the PR region interfaces. Hardware clears this bit after unfreeze_status is high. Write 0 to this bit to terminate the unfreeze request. Do not assert this bit and the freeze_req bit at the same time. If both freeze_req and unfreeze_req assert at the same time, it is an invalid operation.
1	reset_req	R/W	0	Write 1 to start resetting the PR persona. Write 0 to stop resetting the PR persona.
0	freeze_req	R/W	0	Write 1 to this bit to start freezing the PR region interfaces. Hardware clears this bit after freeze_status is high.

continued...

Bit	Fields	Access	Default Value	Description
				Write 0 to this bit to terminate the freeze request if the PR region never returns `stop_ack` after this bit asserts. Do not assert this bit and the `unfreeze_req` bit at the same time. Asserting `freeze_req` and `unfreeze_req` simultaneously is an invalid operation.

Table 41. freeze_illegal_request

Bit	Fields	Access	Default Value	Description
31:n	Reserved	N/A	0x0	Reserved bits. Reading these bits always returns zeros.
n-1:0	illegal_request	R/W	0	High on any bit of this bus indicates a read or write issue by a static region master when an Avalon memory-mapped slave freeze bridge is in the freeze state. Identify which freeze bridge has an illegal request by checking each bit on the bus. For example, when `illegal_request` bit 2 is high, an illegal request occurred in the freeze bridge that connects to interface `freeze_conduit_in2` This bus triggers the interrupt signal. Write 1 to clear this bit. n is the number of bridges.

Table 42. freeze_reg_version

Bit	Fields	Access	Default Value	Description
31:0	Version Register	Read-Only	AD000003	This register bit indicates the CSR register version number. Currently the CSR register is version 0xAD000003.

2.5.2. Parameters

The Partial Reconfiguration Region Controller IP core supports customization of the following parameters.

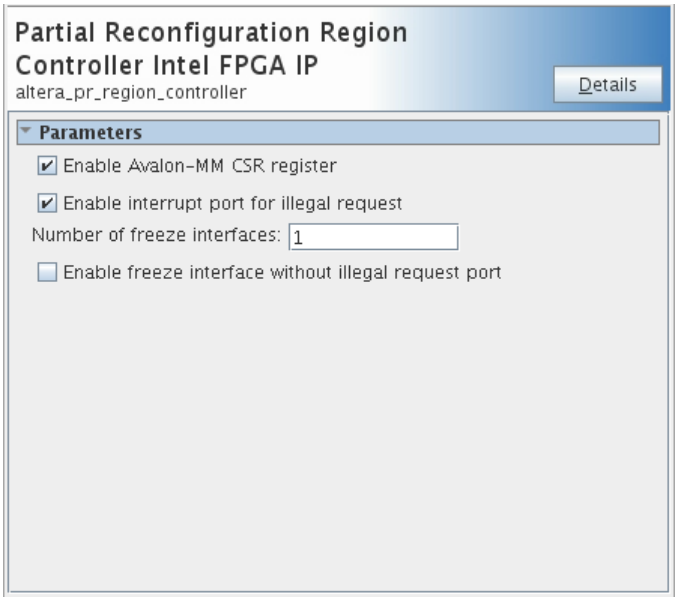
Table 43. Partial Reconfiguration Region Controller Parameter Settings

Parameter	Value	Default	Description
Enable Avalon-MM CSR register	On/Off	On	Enables Avalon memory-mapped CSR registers in the PR region controller. Disable this option to expose a conduit interface and not instantiate the CSR block.
Enable interrupt port for illegal request	On/Off	On	Enables the interrupt port for illegal operations in the PR region controller.

continued...

Parameter	Value	Default	Description
Number of freeze interfaces	*number*		Specifies the number of freeze interfaces for freeze operations. You can connect each freeze interface to a freeze bridge or you can use the interface to control other freeze logic.
Enable freeze interface without illegal request port	On/Off	Off	Enables creation of additional freeze interface, without the illegal request port.
Specify the number of freeze interfaces without illegal request port	*number*		Specifies the number of freeze interfaces without an illegal request port for freeze operations. Only available when you turn on **Enable freeze interface without illegal request port**.

Figure 76. Partial Reconfiguration Region Controller Parameter Editor



2.5.3. Ports

The Partial Reconfiguration Region Controller IP has the following ports.

Table 44. Freeze CSR Block Ports

These ports are available when **Enable Avalon Memory-Mapped CSR Register** is **On**.

Port	Width	Direction	Description
`clock_clk`	1	Input	IP core input clock.
Reset			
`reset_reset`	1	Input	Synchronous reset.
`avl_csr_addr`	2	Input	Avalon memory-mapped address bus. The address bus is in word addressing.
`avl_csr_read`	1	Input	Avalon memory-mapped read control to CSR block.
`avl_csr_write`	1	Input	Avalon memory-mapped write control to CSR.

continued...

Port	Width	Direction	Description
avl_csr_writedata	32	Input	Avalon memory-mapped write data bus to CSR.
avl_csr_readdata	32	Output	Avalon memory-mapped read data bus from CSR.
interrupt_sender_irq	1	output	Trigger by illegal read or illegal write.

Table 45. Freeze Control Block Ports

Port	Width	Direction	Description
pr_handshake_stop_req	1	Output	An assertion on this output requests that the PR persona stop executing.
pr_handshake_stop_ack	1	Input	A value of 1 on this input acknowledges that the executing PR persona stops executing and a new persona can replace it.
pr_handshake_start_req	1	Output	An assertion on this output requests that the new PR persona starts executing.
pr_handshake_start_ack	1	Input	A value of 1 on this input acknowledges that the new PR persona starts executing and can stop executing on a pr_handshake_stop_req.
conduit_control_freeze_req	1	Input	Write 1 on this bit to start freezing the PR region interfaces.
conduit_control_unfreeze_req	1	Input	Write 1 on this bit to stop freezing the PR region interfaces.
conduit_control_freeze_status	1	Output	High on this bit indicates that the PR region is successfully goes into freezing state.
conduit_control_reset	1	Input	Write 1 on this bit to reset the PR region.
conduit_control_unfreeze_status	1	Output	High on this bit indicates that the PR region successfully leaves freezing state.
conduit_control_illegal_req	n	Output	High on this bit indicates illegal data transactions occurring through a Freeze Bridge IP when freeze is active.

Table 46. Conduit Splitter and Merger Interface Ports

Signal	Width	Direction	Description
bridge_freeze0_freeze	1	Output	This output connects to the freeze input signal of a freeze bridge IP or to control other freeze logic. (Multiple interfaces generate according to the number of freeze interfaces)
bridge_freeze0_illegal_request	1	Input	This input connects to the illegal_request output signal from an instance of the Freeze Bridge IP.

Figure 77. Partial Reconfiguration Region Controller Interface Ports (Control and Status Register Block Enabled)

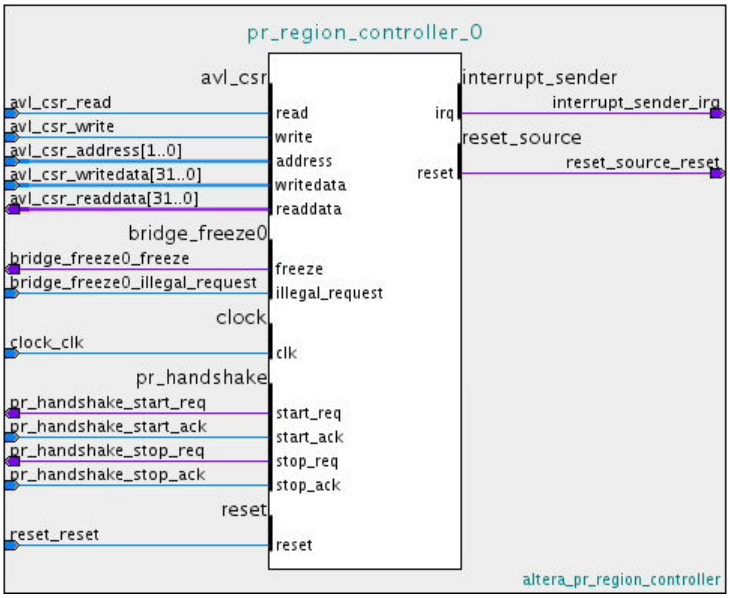


Figure 78. Partial Reconfiguration Region Controller Interface Ports (Control and Status Register Block Disabled)

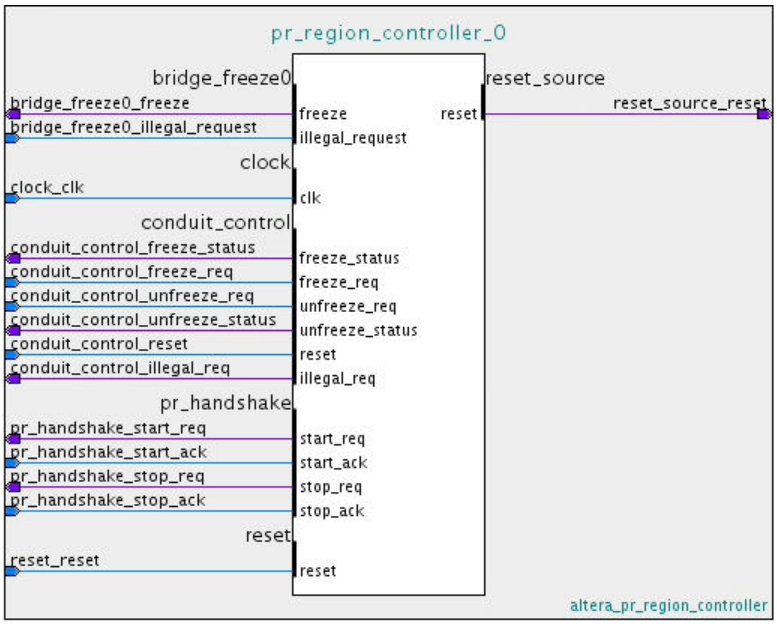

2.6. Avalon Memory-Mapped Partial Reconfiguration Freeze Bridge IP

The Avalon Memory-Mapped Partial Reconfiguration Freeze Bridge Intel FPGA IP freezes a PR region Avalon memory-mapped interface when the `freeze` input signal is high. It is recommended that each Avalon memory-mapped interface to a PR region use an instance of the Freeze Bridge IP.

Figure 79. Avalon Memory-Mapped Partial Reconfiguration Freeze Bridge IP

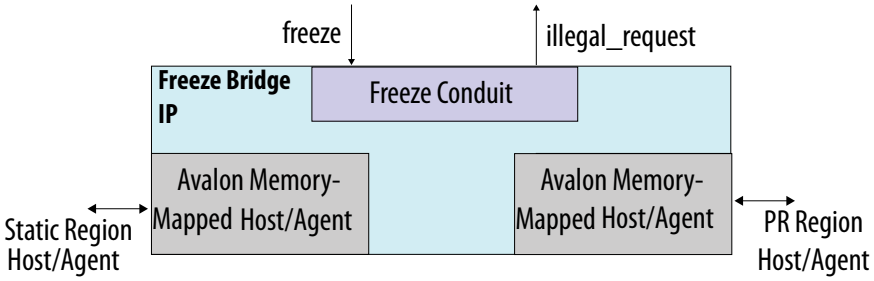

Table 47. Read and Write Request to PR Region Avalon Memory-Mapped Agent Interface

The Freeze Bridge handles read and write transactions differently for each of the following possible interface configurations. The Freeze Bridge is in the freeze state until the PR region or PR region controller asserts the `freeze` signal.

Interface Connection	Behavior
Read request to Avalon memory-mapped slave interface in PR region	1. During the `freeze` state, any read transaction responds with bogus data <h'DEADBEEF>. The corresponding `freeze_illegal_request` register bit sets. 2. During the `freeze` state, `readrequest`, `writerequest`, `waitrequest`, `beginbursttransfer`, `lock`, and `debugaccess` signals in the PR region interface tie low. 3. The Avalon memory-mapped agent response signal constantly returns 2'b10, to indicate an unsuccessful transaction from an endpoint agent. 4. If you disable **Enable Freeze port from PR region**, the IP generates no responses.
Write request to slave interface in PR region	1. The Freeze Bridge ignores any write transactions during the `freeze` state. The Freeze Bridge pulls the `waitrequest`, `beginbursttransfer`, `lock` and `debugaccess` signals low. The IP sets the corresponding `freeze_illegal_request` register bit. 2. The Avalon memory-mapped agent response signal updates with 2'b10 to indicate an unsuccessful transaction from an endpoint agent. 3. If you disable **Enable Freeze port from PR region**, the IP generates no responses.

Table 48. Read and Write Request from PR Region Avalon Memory Mapped Host Interface

Interface Connection	Behavior
Read/Write request from Avalon-MM master interface in PR region (old or new persona)	1. During the `freeze` state, the IP ignores the read and write signals from the PR region. 2. The read and write signals to the static region deassert.

Table 49. Avalon-MM Partial Reconfiguration Freeze Bridge Signal Behavior

The table below summarizes the Avalon interface output signal behavior when the Freeze Bridge is in a frozen state. When not frozen, all signals are just pass-through.

Signal	Agent Bridge	Host Bridge
write	'b0 (tie low)	'b0 (tie low)
read	'b0 (tie low)	'b0 (tie low)
address	Pass through	Pass through
writedata	Pass through	Pass through
readdata	Return <h'DEADBEEF> always	Pass through
byteenable	Pass through	Pass through
burstcount	Pass through	Pass through
beginbursttransfer	'b0 (tie low)	'b0 (tie low)
debugaccess	'b0 (tie low)	'b0 (tie low)
readdatavalid	Return 'b1 when there is a request, else 'b0	Pass through
waitrequest	Return 'b1 when there is a request, else 'b0	'b0 (tie low)
response	Return 'b10 always	Pass through
lock	'b0 (tie low)	'b0 (tie low)
writeresponsevalid	Return 'b1 when there is a request, else 'b0	Pass through

2.6.1. Parameters

The Avalon Memory-Mapped Partial Reconfiguration Freeze Bridge IP core supports customization of the following parameters.

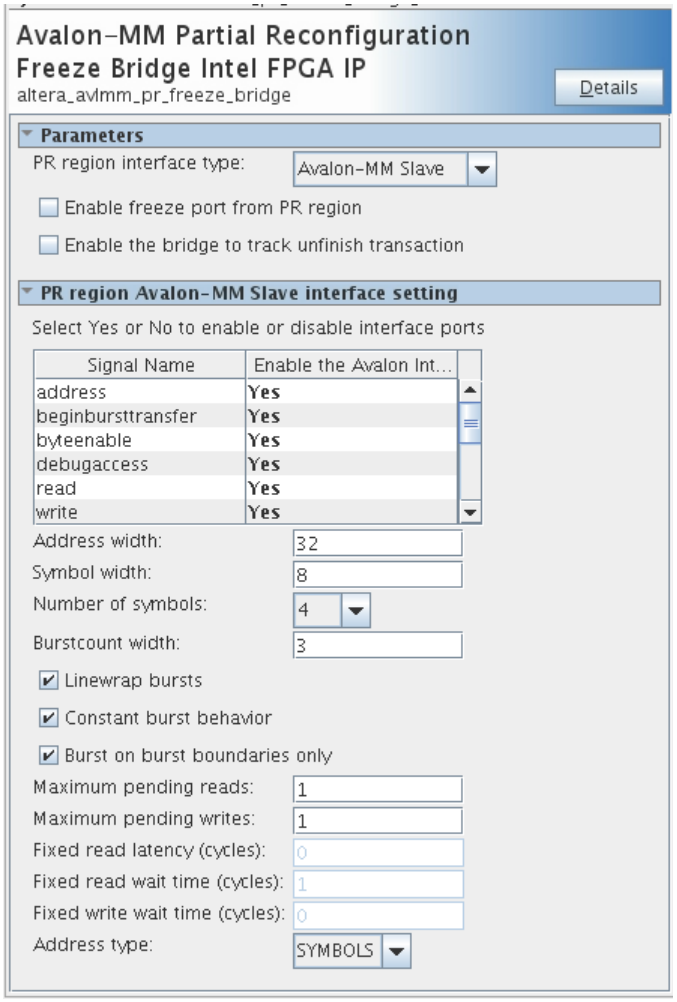
Table 50. Parameters

Parameter	Values	Description
PR region interface Type	**Avalon-MM Slave/Avalon-MM Master**	Specifies the interface type for interfacing the PR region with the Freeze Bridge.
Enable Freeze port from PR region	**On/Off**	Enables the `freeze` port that freezes all the outputs of each PR region to a known constant value. Freezing prevents the signal receivers in the static region from receiving undefined signals during the partial reconfiguration process. The freeze of a bridge is the logical OR of this signal from the PR region, and the freeze from the PR region controller.
Enable the bridge to track unfinished transaction	**On/Off**	Enables the bridge to track unfinished transactions before freezing the Avalon interface. Turn on this option when there is no custom logic to stop the Avalon transaction between the PR region and the static region. If you do not need this feature, disable this option to reduce the size of the IP.
Enabled Avalon Interface Signal	**Yes/No**	Enable (**Yes**) or disable (**No**) specific optional Freeze Bridge interface ports.
Address width	*<1-64>*	Address width in bits.

continued...

Parameter	Values	Description
Symbol width	<*number*>	Data symbol width in bits. The symbol width should be 8 for byte-oriented interfaces.
Number of symbols	<*number*>	Number of symbols per word.
Burstcount width	<*number*>	The width of the burst count in bits.
Linewrap burst	**On**/Off	When **On**, the address for bursts wraps instead of incrementing. With a wrapping burst, when the address reaches a burst boundary, the address wraps back to the previous burst boundary. Consequently, the IP uses only the low order bits for addressing.
Constant burst behavior	**On**/Off	When **On**, memory bursts are constant.
Burst on burst boundaries only	**On**/Off	When **On**, memory bursts are aligned to the address size.
Maximum pending reads	<*number*>	The maximum number of pending reads that the slave can queue.
Maximum pending writes	<*number*>	The maximum number of pending writes that the slave can queue.
Fixed read latency (cycles)	<*number*>	Sets the read latency for fixed-latency slaves. Not useful on interfaces that include the `readdatavalid` signal.
Fixed read wait time (cycles)	<*number*>	For master interfaces that do not use the `waitrequest` signal. The read wait time indicates the number of cycles before the master responds to a read. The timing is as if the master asserted `waitrequest` for this number of cycles.
Fixed write wait time (cycles)	<*number*>	For master interfaces that do not use the `waitrequest` signal. The write wait time indicates the number of cycles before the master accepts a write.
Address type	**WORDS/SYMBOLS**	Sets slave interface address type to symbols or words.

Figure 80. Parameter Editor



2.6.2. Interface Ports

The Avalon Memory-Mapped Partial Reconfiguration Freeze Bridge IP core has the following interface ports.

Table 51. Interface Ports

Port	Width	Direction	Description
`clock`	1	Input	Input clock for the IP.
`reset_n`	1	Input	Synchronous reset for the IP.

continued...

Port	Width	Direction	Description
freeze_conduit_freeze	1	Input	When this signal is high, the bridge handles any current transaction properly then freezes the Avalon memory-mapped PR interfaces.
freeze_conduit_illegal_request	1	Output	High on this bus indicates that an illegal request was issued to the bridge during the freeze state.
pr_freeze_pr_freeze	1	Input	Enabled freeze port coming from the PR region.

Table 52. Avalon Memory-Mapped Agent to PR Region Host Interface Ports

Port	Width	Direction	Description
slv_bridge_to_pr_read	1	Output	Optional Avalon memory-mapped agent bridge to PR region read port.
slv_bridge_to_pr_waitrequest	1	Input	Optional Avalon memory-mapped agent bridge to PR region waitrequest port.
slv_bridge_to_pr_write	1	Output	Optional Avalon memory-mapped agent bridge to PR region write port.
slv_bridge_to_pr_address	32	Output	Optional Avalon memory-mapped agent bridge to PR region address port.
slv_bridge_to_pr_byteenable	4	Output	Optional Avalon memory-mapped agent bridge to PR region byteenable port.
slv_bridge_to_pr_writedata	32	Output	Optional Avalon memory-mapped agent bridge to PR region writedata port.
slv_bridge_to_pr_readdata	32	Input	Optional Avalon memory-mapped agent bridge to PR region readdata port.
slv_bridge_to_pr_burstcount	3	Output	Optional Avalon memory-mapped agent bridge to PR region burstcount port.
slv_bridge_to_pr_readdatavalid	1	Input	Optional Avalon memory-mapped agent bridge to PR region readdatavalid port.
slv_bridge_to_pr_beginbursttransfer	1	Output	Optional Avalon-MM agent bridge to PR region beginbursttransfer port.
slv_bridge_to_pr_debugaccess	1	Output	Optional Avalon memory-mapped agent bridge to PR region debugaccess port.
slv_bridge_to_pr_response	2	Input	Optional Avalon memory-mapped agent bridge to PR region response port.
slv_bridge_to_pr_lock	1	Output	Optional Avalon-MM agent bridge to PR region lock port.
slv_bridge_to_pr_writeresponsevalid	1	Input	Optional Avalon memory-mapped agent bridge to PR region writeresponsevalid port.

Table 53. Avalon Memory-Mapped Agent to Static Region Master Interface Ports

Note: Same setting as Avalon memory-mapped master to PR region agent interface.

Port	Width	Direction	Description
slv_bridge_to_sr_read	1	Input	Avalon memory-mapped agent bridge to static region read port.
slv_bridge_to_sr_waitrequest	1	Output	Avalon memory-mapped agent bridge to static region waitrequest port.
slv_bridge_to_sr_write	1	Input	Avalon memory-mapped agent bridge to static region write port.
slv_bridge_to_sr_address	32	Input	Avalon memory-mapped agent bridge to static region address port.
slv_bridge_to_sr_byteenable	4	Input	Avalon memory-mapped agent bridge to static region byteenable port.
slv_bridge_to_sr_writedata	32	Input	Avalon memory-mapped agent bridge to static region writedata port.
slv_bridge_to_sr_readdata	32	Output	Avalon memory-mapped agent bridge to static region readdata port.
slv_bridge_to_sr_burstcount	3	Input	Avalon memory-mapped agent bridge to static region burstcount port.
slv_bridge_to_sr_beginbursttransfer	1	Input	Avalon memory-mapped agent bridge to static region beginbursttransfer port.
slv_bridge_to_sr_debugaccess	1	Input	Avalon-MM agent bridge to static region debugaccess port.
slv_bridge_to_sr_response	2	Output	Avalon memory-mapped agent bridge to static region response port.
slv_bridge_to_sr_lock	1	Input	Avalon memory-mapped agent bridge to static region lock port.
slv_bridge_to_sr_writeresponsevalid	1	Output	Avalon memory-mapped agent bridge to static region writereponsevalid port.

Table 54. Avalon Memory-Mapped Master to PR Region Agent Interface Ports

Port	Width	Direction	Description
mst_bridge_to_pr_read	1	Input	Optional Avalon memory-mapped master bridge to PR region read port.
mst_bridge_to_pr_waitrequest	1	Output	Optional Avalon memory-mapped master bridge to PR region waitrequest port.
mst_bridge_to_pr_write	1	Input	Optional Avalon memory-mapped master bridge to PR region write port.
mst_bridge_to_pr_address	32	Input	Optional Avalon memory-mapped master bridge to PR region address port.
mst_bridge_to_pr_byteenable	4	Input	Optional Avalon-MM master bridge to PR region byteenable port.
mst_bridge_to_pr_writedata	32	Input	Optional Avalon-MM master bridge to PR region writedata port.

continued...

Port	Width	Direction	Description
mst_bridge_to_pr_readdata	32	Output	Optional Avalon memory-mapped master bridge to PR region readdata port.
mst_bridge_to_pr_burstcount	3	Input	Optional Avalon memory-mapped master bridge to PR region burstcount port.
mst_bridge_to_pr_readdatavalid	1	Output	Optional Avalon memory-mapped master bridge to PR region readdatavalid port.
mst_bridge_to_pr_beginbursttransfer	1	Input	Optional Avalon memory-mapped master bridge to PR region beginbursttransfer port.
mst_bridge_to_pr_debugaccess	1	Input	Optional Avalon memory-mapped master bridge to PR region debugaccess port.
mst_bridge_to_pr_response	2	Output	Optional Avalon memory-mapped master bridge to PR region response port.
mst_bridge_to_pr_lock	1	Input	Optional Avalon memory-mapped master bridge to PR region lock port.
mst_bridge_to_pr_writeresponsevalid	1	Output	Optional Avalon memory-mapped master bridge to PR region writeresponsevalid port.

Table 55. Avalon Memory-Mapped Master to Static Region Agent Interface Ports

Same setting as Avalon Memory-Mapped agent to PR region master interface.

Port	Width	Direction	Description
mst_bridge_to_sr_read	1	Output	Avalon memory-mapped master bridge to static region read port.
mst_bridge_to_sr_waitrequest	1	Input	Avalon memory-mapped bridge to static region waitrequest port.
mst_bridge_to_sr_write	1	Output	Avalon memory-mapped master bridge to static region write port.
mst_bridge_to_sr_address	32	Output	Avalon memory-mapped master bridge to static region address port.
mst_bridge_to_sr_byteenable	4	Output	Avalon memory-mapped master bridge to static region byteenable port.
mst_bridge_to_sr_writedata	32	Output	Avalon memory-mapped master bridge to static region writedata port.
mst_bridge_to_sr_readdata	32	Input	Avalon memory-mapped master bridge to static region readdata port.
mst_bridge_to_sr_burstcount	3	Output	Avalon memory-mapped master bridge to static region burstcount port.
mst_bridge_to_sr_readdatavalid	1	Input	Avalon memory-mapped master bridge to static region readdatavalid port.
mst_bridge_to_sr_beginbursttransfer	1	Output	Avalon memory-mapped master bridge to static region beginbursttransfer port.
mst_bridge_to_sr_debugaccess	1	Output	Avalon memory-mapped master bridge to static region debugaccess port.

continued...

Port	Width	Direction	Description
mst_bridge_to_sr_response	2	Input	Avalon memory-mapped master bridge to static region response port.
mst_bridge_to_sr_lock	1	Output	Avalon memory-mapped master bridge to static region lock port.
mst_bridge_to_sr_writeresponsevalid	1	Input	Avalon memory-mapped master bridge to static region writeresponsevalid port.

Figure 81. Avalon Memory-Mapped Host Interface Ports

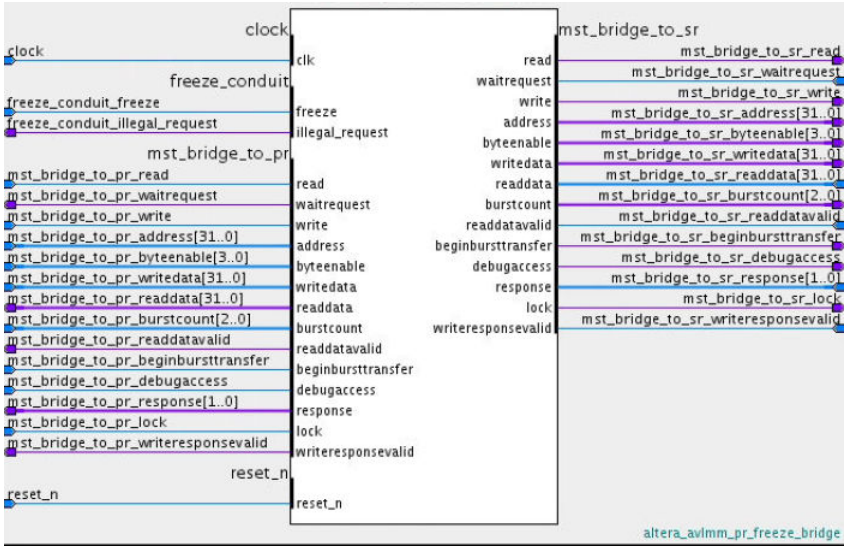


Figure 82. Avalon Memory-Mapped Agent Interface Ports

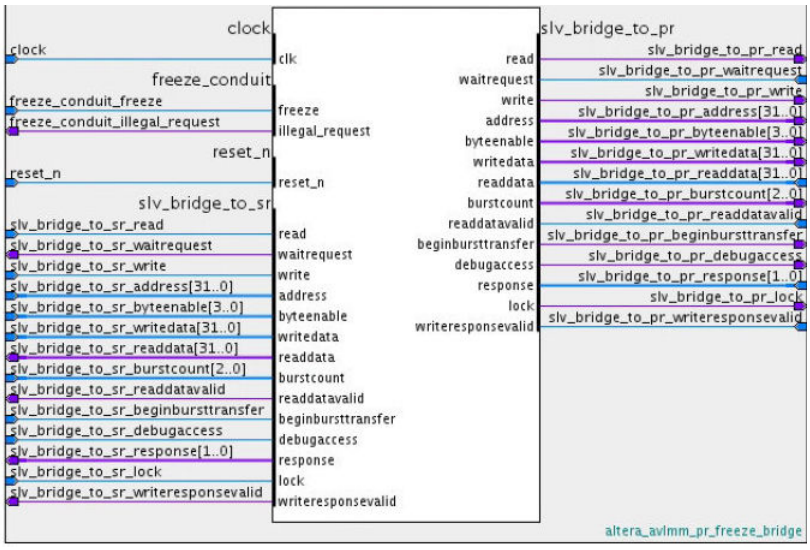

2.7. Avalon Streaming Partial Reconfiguration Freeze Bridge IP

The Avalon Streaming Partial Reconfiguration Freeze Bridge Intel FPGA IP freezes a PR region Avalon streaming interface when the `freeze` input signal is high. The Avalon Streaming Partial Reconfiguration Freeze Bridge IP ensures that any transaction is complete before freezing the connected interface. It is recommended that each Avalon streaming interface to a PR region use an instance of the Freeze Bridge IP.

Figure 83. Avalon Streaming Partial Reconfiguration Freeze Bridge

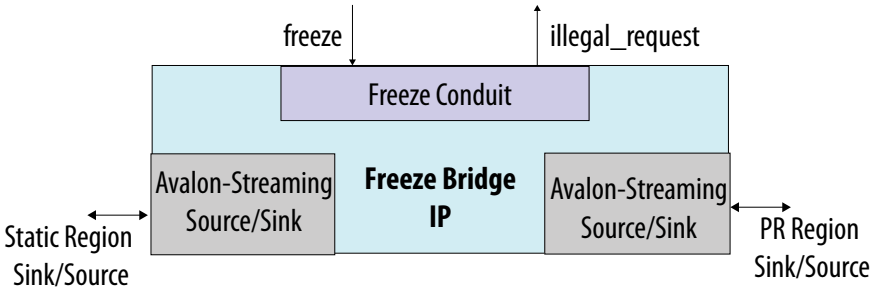

Table 56. Avalon Streaming Source Freeze Bridge Interface Behavior

Interface Type	Behavior
Source interface in the PR region with packet transfer (old or new persona)	1. When the `freeze` signal goes high, the Freeze Bridge handles the `startofpacket`, `endofpacket`, and `empty` bits and does not send transactions to the static region. 2. When the Freeze Bridge detects a `startofpacket` transaction without a corresponding `endofpacket` during the frozen state, this indicates an unfinished transaction. 3. The bridge then completes the transaction by asserting `valid` and `endofpacket` high to the static region for one clock cycle. 4. The `channel` signal remains constant, while data bits are set to `'hDEADBEEF` and error bit is set to `1'b1`. 5. The `illegal_request` output signal triggers update of the CSR register in the Partial Reconfiguration Region Controller.
Source interface in the PR region without packet transfer (old or new persona)	When the `freeze` signal is high, the Freeze Bridge does not send transactions to the static region. The Freeze Bridge remains idle until the bridge leaves the frozen state.
Source interface in the PR region with max_channel > 1 (old or new persona)	When multiple channels transfer unfinished transactions, the Freeze Bridge tracks the `channel` values to ensure that all packet transactions from different channels end by asserting the `endofpacket` bit during the frozen state.
Source interface in the PR region with ready_latency > 0 (old or new persona)	When the Freeze Bridge drives `endofpacket`, `valid`, or `channel` outputs to the static region, the Freeze Bridge reads the `ready_latency` value. The `ready_latency` value defines the actual clock cycle when the sink component is ready for data.

Figure 84. Source Bridge Handling of Unfinished Packet Transaction During Freeze

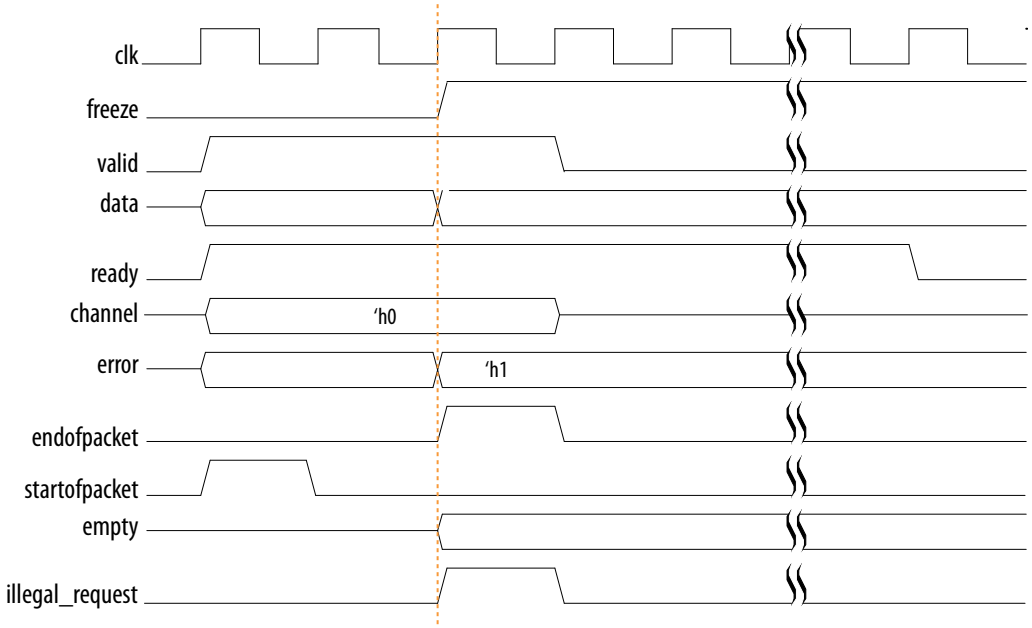

Figure 85. PR Freeze Bridge Asserting valid Signal to End Packet Transactions

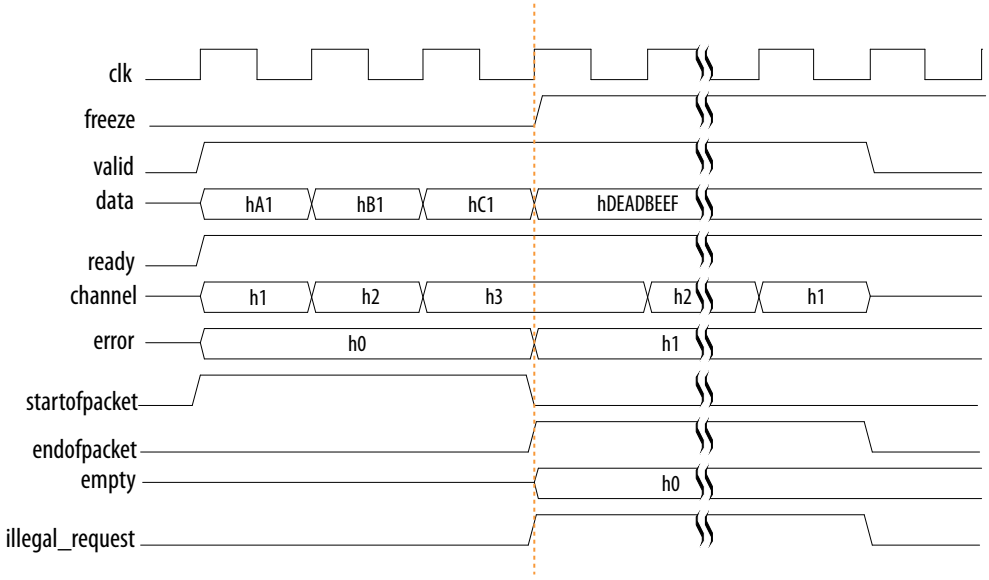

Table 57. Avalon Streaming Sink Freeze Bridge Interface Behavior

Interface Type	Behavior
Sink interface in PR region	For transactions that includes packet transfers, when the `freeze` signal goes high, the Freeze Bridge holds the `ready` signal high to the static region source until any unfinished transaction completes.

continued...

Interface Type	Behavior
	For transactions that do not include packet transfers, when the `freeze` signal goes high, the Freeze Bridge holds the `ready` signal low during the freeze period. The `illegal_request` signal asserts high to indicate that the current transaction is an error. Configure the design to stop sending transactions to the PR region after the `illegal_request` signal is high.
Sink interface in PR region with ready_latency > 0	When the Freeze Bridge drives `endofpacket`, `valid`, or `channel` outputs to the PR region, the Freeze Bridge must observe the `ready_latency` value. The `ready_latency` value defines the actual clock cycle when the sink component is ready for data.

2.7.1. Parameters

The Avalon Streaming Partial Reconfiguration Freeze Bridge IP core supports customization of the following parameters:

Figure 86. Parameter Editor

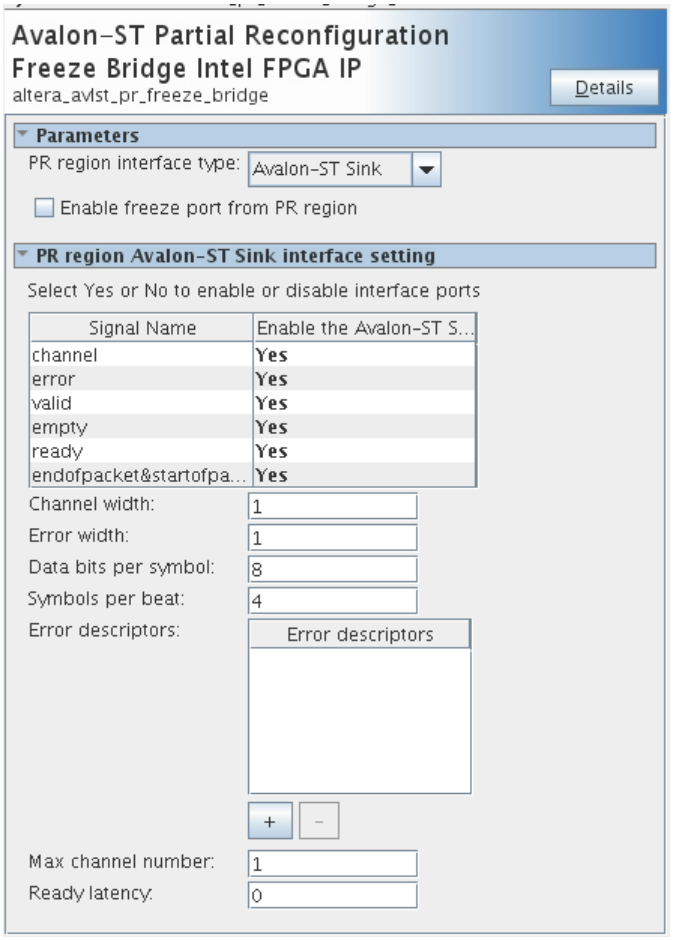

Table 58. Parameters

Parameter	Values	Description
PR region Interface Type	**Avalon-ST Source/Avalon-ST Sink**	Specifies the interface type for interfacing the PR region with the freeze bridge.
Enable Freeze port from PR region	**On/Off**	Enables the freeze port to freeze all the outputs of each PR region to a known constant value. Freezing prevents the signal receivers in the static region from receiving undefined signals during the partial reconfiguration process.
Select Yes or No to enable or disable interface ports	**Yes/No**	Enables or disables specific optional freeze bridge interface ports.
Channel width	*<1-128>*	Specifies the width of the channel signal.
Error width	*<1-256>*	Specifies the width of the error signal.
Data bits per symbol	*<1-512>*	Specifies the number of bits per symbol.
Symbols per beat	*<1-512>*	Specifies the number of symbols that transfer on every valid clock cycle.
Error descriptors	*<text>*	Specifies one or more strings to describe the error condition for each bit of the error port on the sink interface connected to the source interface. Click the plus or minus buttons to add or remove descriptors.
Max channel number	*<0-255>*	Specifies the maximum number of output channels.
Ready latency	*<0-8>*	Specifies what ready latency to expect from the source interface connected to the sink interface. The ready latency is the number of cycles from the time `ready` asserts until valid data is driven.

2.7.2. Ports

The Avalon Streaming Partial Reconfiguration Freeze Bridge IP has the following ports:

Figure 87. Avalon Streaming Sink Interface Ports

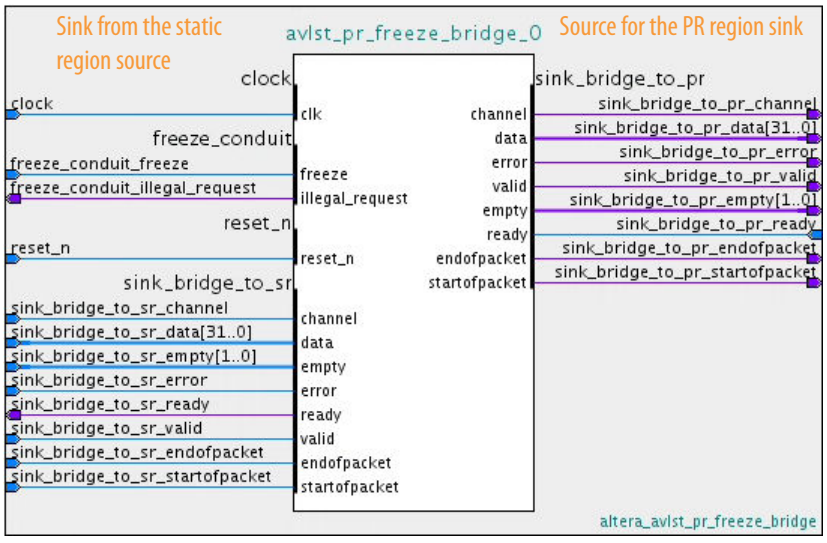

Figure 88. Avalon Streaming Source Interface Ports

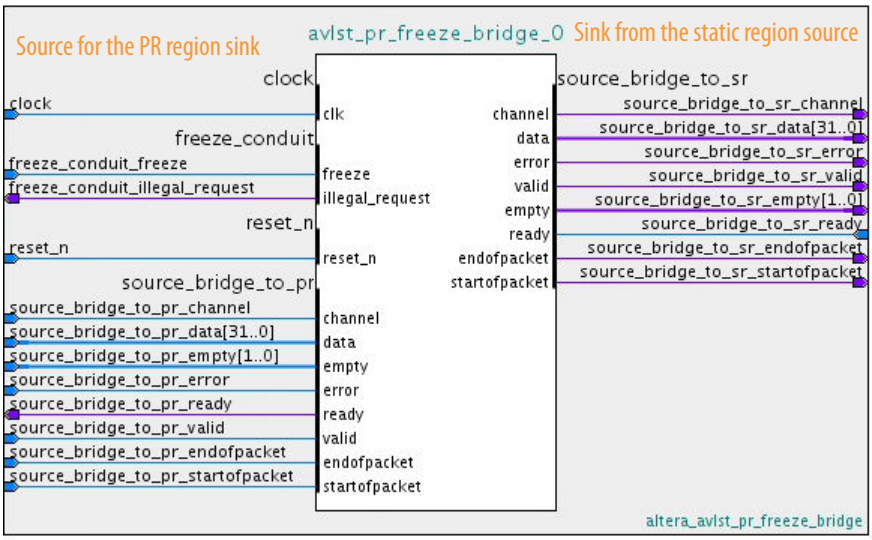

Table 59. Avalon Streaming Interface Ports

Port	Width	Direction	Description
clock	1	Input	Input clock for the IP.
freeze_conduit_freeze	1	Input	When this signal is high, the bridge handles any current transaction properly then freezes the PR interfaces.
freeze_conduit_illegal_request	1	Output	High on this bus indicates that an illegal request was issued to the bridge during the freeze state. *n* – number of freeze bridge
pr_freeze_pr_freeze	1	Input	Enabled freeze port from the PR region.
reset_n	1	Input	Synchronous reset for the IP.

Table 60. Avalon Streaming Sink to Static Region Interface Ports

Same setting as Avalon streaming sink to PR region interface.

Port	Width	Direction	Description
sink_bridge_to_sr_channel	1	Input	Avalon streaming sink bridge to static region channel port.
sink_bridge_to_sr_data	32	Input	Avalon streaming sink bridge to static region data port.
sink_bridge_to_sr_empty	2	Input	Avalon streaming sink bridge to static region empty port.
sink_bridge_to_sr_error	1	Input	Avalon streaming sink bridge to static region error port.
sink_bridge_to_sr_ready	1	Output	Avalon streaming sink bridge to static region ready port.

continued...

Port	Width	Direction	Description
sink_bridge_to_sr_valid	1	Input	Avalon streaming sink bridge to static region valid port.
sink_bridge_to_sr_endofpacket	1	Input	Avalon streaming sink bridge to static region endofpacket port.
sink_bridge_to_sr_startofpacket	1	Input	Avalon streaming sink bridge to static region startofpacket port.

Table 61. Avalon-Streaming Sink to PR Region Interface Ports

Port	Width	Direction	Description
sink_bridge_to_pr_channel	1	Output	Optional Avalon streaming sink bridge to PR region channel port.
sink_bridge_to_pr_data	32	Output	Optional Avalon streaming sink bridge to PR region data port.
sink_bridge_to_pr_empty	2	Output	Optional Avalon streaming sink bridge to PR region empty port.
sink_bridge_to_pr_error	1	Output	Optional Avalon streaming sink bridge to PR region error port.
sink_bridge_to_pr_ready	1	Input	Optional Avalon-ST sink bridge to PR region ready port.
sink_bridge_to_pr_valid	1	Output	Optional Avalon streaming sink bridge to PR region valid port.
sink_bridge_to_pr_endofpacket	1	Output	Optional Avalon streaming sink bridge to PR region endofpacket port.
sink_bridge_to_pr_startofpacket	1	Output	Optional Avalon streaming sink bridge to PR region startofpacket port.

Table 62. Avalon Streaming Source to Static Region Interface Ports

Same setting as Avalon streaming source to PR region interface.

Port	Width	Direction	Description
source_bridge_to_sr_channel	1	Output	Avalon streaming source bridge to static region channel port.
source_bridge_to_sr_data	32	Output	Avalon streaming source bridge to static region data port.
source_bridge_to_sr_empty	2	Output	Avalon streaming source bridge to static region empty port.
source_bridge_to_sr_error	1	Output	Avalon streaming source bridge to static region error port.
source_bridge_to_sr_ready	1	Input	Avalon streaming source bridge to static region ready port.
source_bridge_to_sr_valid	1	Output	Avalon streaming source bridge to static region valid port.
source_bridge_to_sr_endofpacket	1	Output	Avalon streaming source bridge to static region endofpacket port.
source_bridge_to_sr_startofpacket	1	Output	Avalon streaming source bridge to static region startofpacket port.

Table 63. Avalon Streaming Source to PR Region Interface Ports

Port	Width	Direction	Description
source_bridge_to_pr_channel	1	Input	Optional Avalon streaming source bridge to PR region channel port.
source_bridge_to_pr_data	32	Input	Optional Avalon streaming source bridge to PR region data port.
source_bridge_to_pr_empty	2	Input	Optional Avalon streaming source bridge to PR region empty port.
source_bridge_to_pr_error	1	Input	Optional Avalon-ST source bridge to PR region error port.
source_bridge_to_pr_ready	1	Output	Optional Avalon streaming source bridge to PR region ready port.
source_bridge_to_pr_valid	1	Input	Optional Avalon streaming source bridge to PR region valid port.
source_bridge_to_pr_endofpacket	1	Input	Optional Avalon streaming source bridge to PR region endofpacket port.
source_bridge_to_pr_startofpacket	1	Input	Optional Avalon streaming source bridge to PR region startofpacket port.

2.8. Generating and Simulating Intel FPGA IP

Use the following information to generate and simulate an IP core variation.

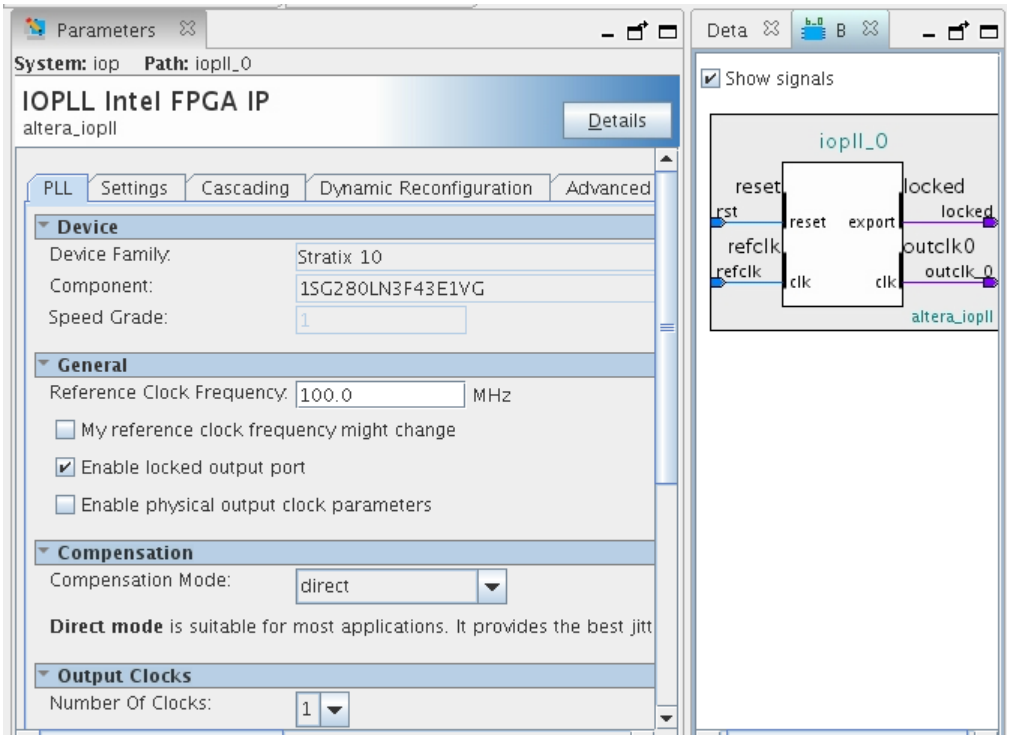
2.8.1. Specifying the IP Core Parameters and Options (Quartus Prime Pro Edition)

Quickly configure Intel FPGA IP cores in the Quartus Prime parameter editor. Double-click any component in the IP Catalog to launch the parameter editor. The parameter editor allows you to define a custom variation of the IP core. The parameter editor generates the IP variation synthesis and optional simulation files, and adds the `.ip` file representing the variation to your project automatically.

Follow these steps to locate, instantiate, and customize an IP core in the parameter editor:

1. Create or open an Quartus Prime project (`.qpf`) to contain the instantiated IP variation.
2. In the IP Catalog (**Tools ➤ IP Catalog**), locate and double-click the name of the IP core to customize. To locate a specific component, type some or all of the component's name in the IP Catalog search box. The New IP Variation window appears.
3. Specify a top-level name for your custom IP variation. Do not include spaces in IP variation names or paths. The parameter editor saves the IP variation settings in a file named <*your_ip*>.ip. Click **OK**. The parameter editor appears.

Figure 89. IP Parameter Editor (Quartus Prime Pro Edition)



4. Set the parameter values in the parameter editor and view the block diagram for the component. The **Parameterization Messages** tab at the bottom displays any errors in IP parameters:
   - Optionally, select preset parameter values if provided for your IP core. Presets specify initial parameter values for specific applications.
   - Specify parameters defining the IP core functionality, port configurations, and device-specific features.
   - Specify options for processing the IP core files in other EDA tools.

   Note: Refer to your IP core user guide for information about specific IP core parameters.
5. Click **Generate HDL**. The **Generation** dialog box appears.
6. Specify output file generation options, and then click **Generate**. The synthesis and simulation files generate according to your specifications.
7. To generate a simulation testbench, click **Generate ➤ Generate Testbench System**. Specify testbench generation options, and then click **Generate**.
8. To generate an HDL instantiation template that you can copy and paste into your text editor, click **Generate ➤ Show Instantiation Template**.
9. Click **Finish**. Click **Yes** if prompted to add files representing the IP variation to your project.
10. After generating and instantiating your IP variation, make appropriate pin assignments to connect ports.

Note: Some IP cores generate different HDL implementations according to the IP core parameters. The underlying RTL of these IP cores contains a unique hash code that prevents module name collisions between different variations of the IP core. This unique code remains consistent, given the same IP settings and software version during IP generation. This unique code can change if you edit the IP core's parameters or upgrade the IP core version. To avoid dependency on these unique codes in your simulation environment, refer to *Generating a Combined Simulator Setup Script*.

Introduction to Intel FPGA IP Cores

2.8.2. Running the Freeze Bridge Update script

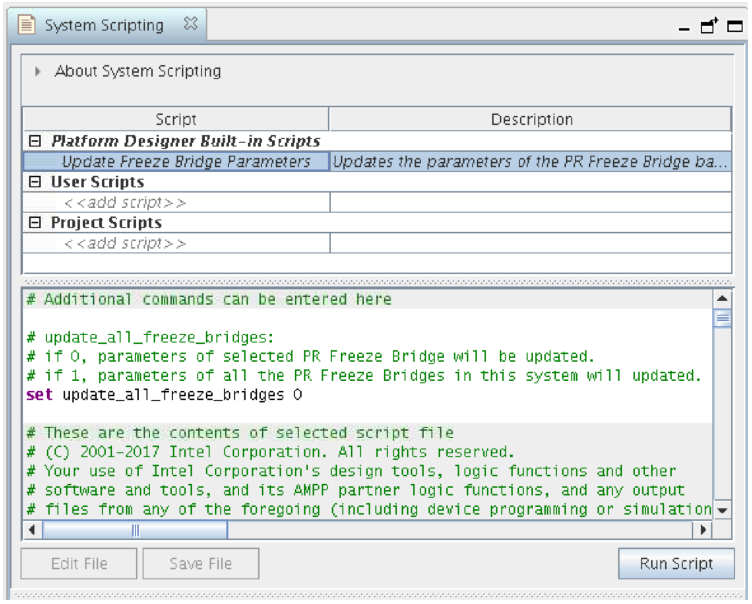
When instantiating the Freeze Bridge as a Platform Designer system component, the interface connections between the Freeze Bridge and the PR region must match, so that Platform Designer inserts no extra interconnect during system generation. Rather than manually matching the Avalon interface properties individually in the parameter editor, you can run the provided Update Freeze Bridge Parameters script to update Freeze Bridge Avalon interface properties automatically.

Running this script updates the host and agent interfaces or the sink and source interfaces of the Freeze Bridge, according to the Avalon property settings of the connecting PR region component.

To run the Update Freeze Bridge Parameters script:

1. Open a Platform Designer system containing one or more instances of the Freeze Bridge component.
2. In Platform Designer, click **View ➤ System Scripting**. The **System Scripting** tab displays **Platform Designer Built-in Scripts**.
3. To update all freeze bridges in your Platform Designer system, set `update_all_freeze_bridges` to 1 in the Additional Commands section of the script. To update only a single freeze bridge, click the freeze bridge instance.
4. Click **Run Script**. The script runs and updates the freeze bridge parameters.

Figure 90. Platform Designer System Scripting Tab



2.8.3. IP Core Generation Output (Quartus Prime Pro Edition)

The Quartus Prime software generates the following output file structure for individual IP cores that are not part of a Platform Designer system.

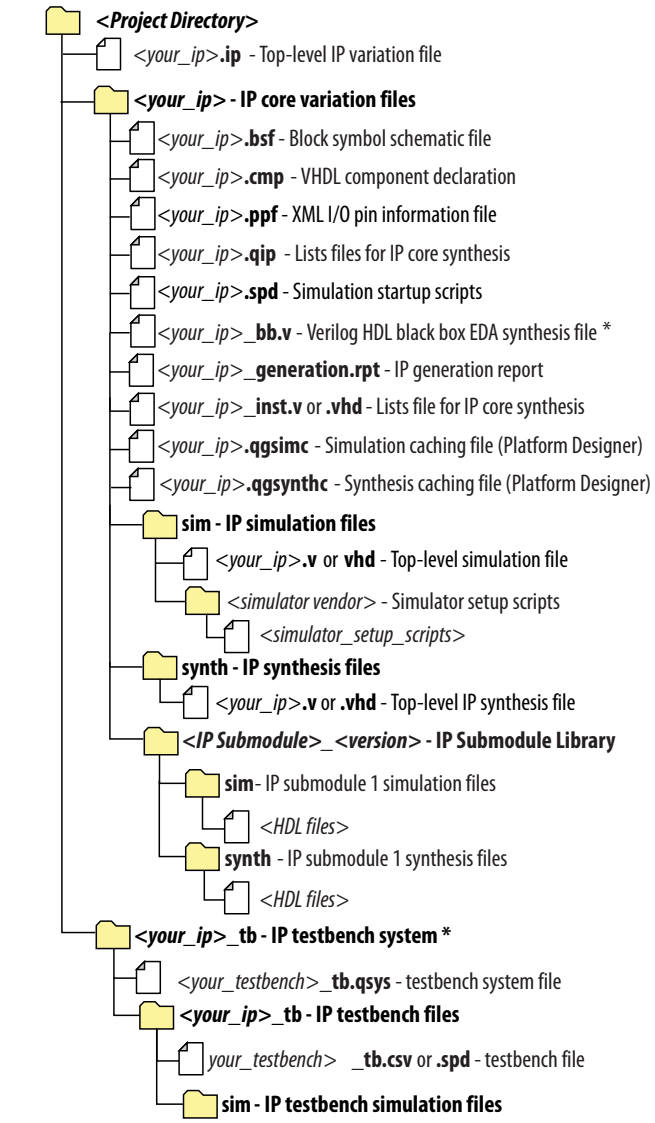
Table 64. Output Files of Intel FPGA IP Generation

File Name	Description
<*your_ip*>.ip	Top-level IP variation file that contains the parameterization of an IP core in your project. If the IP variation is part of a Platform Designer system, the parameter editor also generates a .qsys file.
<*your_ip*>.cmp	The VHDL Component Declaration (.cmp) file is a text file that contains local generic and port definitions that you use in VHDL design files.
<*your_ip*>_generation.rpt	IP or Platform Designer generation log file. Displays a summary of the messages during IP generation.
<*your_ip*>.qgsimc (Platform Designer systems only)	Simulation caching file that compares the .qsys and .ip files with the current parameterization of the Platform Designer system and IP core. This comparison determines if Platform Designer can skip regeneration of the HDL.
<*your_ip*>.qgsynth (Platform Designer systems only)	Synthesis caching file that compares the .qsys and .ip files with the current parameterization of the Platform Designer system and IP core. This comparison determines if Platform Designer can skip regeneration of the HDL.
<*your_ip*>.csv	Contains information about the upgrade status of the IP component.
<*your_ip*>.bsf	A symbol representation of the IP variation for use in Block Diagram Files (.bdf).
<*your_ip*>.spd	Input file that ip-make-simscript requires to generate simulation scripts. The .spd file contains a list of files you generate for simulation, along with information about memories that you initialize.
<*your_ip*>.ppf	The Pin Planner File (.ppf) stores the port and node assignments for IP components you create for use with the Pin Planner.

continued...

File Name	Description
<*your_ip*>_bb.v	Use the Verilog blackbox (_bb.v) file as an empty module declaration for use as a blackbox.
<*your_ip*>_inst.v or _inst.vhd	HDL example instantiation template. Copy and paste the contents of this file into your HDL file to instantiate the IP variation.
<*your_ip*>.regmap	If the IP contains register information, the Quartus Prime software generates the .regmap file. The .regmap file describes the register map information of host and agent interfaces. This file complements the .sopcinfo file by providing more detailed register information about the system. This file enables register display views and user customizable statistics in System Console.
<*your_ip*>.svd	Allows HPS System Debug tools to view the register maps of peripherals that connect to HPS within a Platform Designer system. During synthesis, the Quartus Prime software stores the .svd files for agent interface visible to the System Console hosts in the .sof file in the debug session. System Console reads this section, which Platform Designer queries for register map information. For system agents, Platform Designer accesses the registers by name.
<*your_ip*>.v <*your_ip*>.vhd	HDL files that instantiate each submodule or child IP core for synthesis or simulation.
mentor/	Contains a msim_setup.tcl script to set up and run a simulation with a supported Siemens EDA simulator, such as the QuestaSim simulator.
aldec/	Contains a Riviera-PRO* script rivierapro_setup.tcl to setup and run a simulation.
/synopsys/vcs /synopsys/vcsmx	Contains a shell script vcs_setup.sh to set up and run a VCS* simulation. Contains a shell script vcsmx_setup.sh and synopsys_sim.setup file to set up and run a VCS MX simulation.
/xcelium	Contains an Xcelium* Parallel simulator shell script xcelium_setup.sh and other setup files to set up and run a simulation.
/submodules	Contains HDL files for the IP core submodule.
<*IP submodule*>/	Platform Designer generates /synth and /sim sub-directories for each IP submodule directory that Platform Designer generates.

Figure 91. Individual IP Core Generation Output (Quartus Prime Pro Edition)



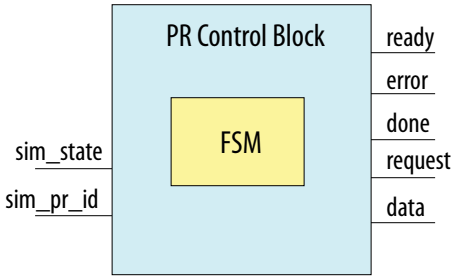
* If supported and enabled for your IP core variation.

2.8.4. Arria 10 and Cyclone 10 GX PR Control Block Simulation Model

The Quartus Prime Pro Edition software supports simulating the delivery of a partial reconfiguration bitstream to the PR control block. This simulation allows you to observe the resulting change and the intermediate effect in a reconfigurable partition.

The Arria 10 and Cyclone 10 GX PR control blocks support PR simulation. Sending a simulation RBF (PR bitstream) allows the PR control block to behave accordingly, to PR simulation success or PR simulation failure. To activate simulation of a specific PR persona in your PR region simulation wrapper, use a PR ID encoded in the simulation RBF, in conjunction with the PR control block. Simulate the PR control block either as standalone, or as part of the simulation file set for the Partial Reconfiguration Controller IP core.

Figure 92. PR Control Block Simulation Model



The PR control block simulation model contains two additional simulation-only ports—`sim_state` and `sim_pr_id`. Connect these simulation ports, and the other ports, to the `twentynm_prblock_if` SystemVerilog interface. This connection allows monitoring of the PR control block using your testbench's PR control block monitor. The Quartus Prime software automatically instantiates the `twentynm_prblock_if` interface when generating the simulation file set of the Partial Reconfiguration IP core. Obtain a reference to the `twentynm_prblock_if` that the IP instantiates by using the `alt_pr_test_pkg::twentynm_prblock_if_mgr` singleton, as shown in the following example:

```
virtual twentynm_prblock_if prblock_if;

alt_pr_test_pkg::twentynm_prblock_if_mgr cb_mgr;

// Get the PR control block from the prblock manager
cb_mgr = alt_pr_test_pkg::twentynm_prblock_if_mgr::get();
prblock_if = cb_mgr.if_ref;
```

The code for the `twentynm_prblock_if` interface is as follows:

```
interface twentynm_prblock_if(input logic pr_clk, input logic clk);

    logic prrequest;
    logic [31:0] data;
    wire error;
    wire ready;
    wire done;
    logic [31:0] sim_only_state;
    wire [31:0] sim_only_pr_id;

    // All signals are async except data
    clocking cb1 @(posedge pr_clk);
        output data;
    endclocking

endinterface : twentynm_prblock_if
```

For more information on the `twentynm_prblock_if` interface, refer to the *<installation directory>*`/eda/sim_lib/altera_lnsim.sv` file.

The simulation state of the PR control block simulation model represents the PR_EVENT_TYPE enumeration state of the control block. The `twentynm_prblock_test_pkg` SystemVerilog package defines these enumerations. These states represent the different allowed states for the control block. The defined control block enumerations are:

```
package twentynm_prblock_test_pkg;
    typedef enum logic [31:0] {
        NONE,
        IDLE,
```

```
        PR_REQUEST,
        PR_IN_PROGRESS,
        PR_COMPLETE_SUCCESS,
        PR_COMPLETE_ERROR,
        PR_INCOMPLETE_EARLY_WITHDRAWL,
        PR_INCOMPLETE_LATE_WITHDRAWL
    } PR_EVENT_TYPE;
```

When the simulation state is PR_IN_PROGRESS, the affected PR region must have its simulation output multiplexes driven to X, by asserting the pr_activate signal. This action simulates the unknown outputs of the PR region during partial reconfiguration. In addition, you must assert the pr_activate signal in the PR simulation model to load all registers in the PR model with the PR activation value.

Once the simulation state reaches PR_COMPLETE_SUCCESS, activate the appropriate PR persona using the appropriate PR region simulation wrapper mux sel signals. You can decode the region, as well as the specific select signal from the sim_only_pr_id signal of the PR control block. This ID corresponds to the encoded ID in the simulation RBF.

Table 65. Required Sequence of Words in Simulation RBF

Step 1 writes zero or more of the following words. All other steps write only 1 word.

1	zero padding blocks	0x00000000
2	PR_HEADER_WORD	0x0000A65C
3	PR_ID	32-bit user ID
4	PRDATA_COUNT_0	0x01234567
5	PRDATA_COUNT_1	0x89ABCDEF
6	PRDATA_COUNT_2	0x02468ACE
7	PRDATA_COUNT_3	0x13579BDF

Note: The PR_ID word is output on the sim_only_pr_id word, starting at PRDATA_COUNT_0. Using a different value for the header or data count results in PR simulation errors.

Related Information

Simulating PR Persona Replacement on page 53

2.8.5. Generating the PR Persona Simulation Model

Use the Quartus Prime EDA Netlist Writer to create the simulation model for a PR persona. The simulation model represents the post-synthesis, gate-level netlist for the persona.

When using the PR simulation model for the persona, the netlist includes a new altera_sim_pr_activate top-level signal for the model. You can asynchronously drive this signal to load all registers in the model with X. This feature allows you to verify the reset sequence of the new persona on PR event completion. Verify the reset sequence through inspection, using SystemVerilog assertions, or using other checkers.

By default, the PR simulation model asynchronously loads X into the register's storage element on `pr_activate` signal assertion. You can parameterize this behavior on a per register basis, or on a simulation-wide default basis. The simulation model supports four built-in modes:

- `load X`
- `load 1`
- `load 0`
- `load rand`

Specify these modes using the SystemVerilog classes:

- `dffeas_pr_load_x`
- `dffeas_load_1`
- `dffeas_load_0`
- `dffeas_load_rand`

Optionally, you can create your own PR activation class, where your class must define the `pr_load` variable to specify the PR activation value.

Follow these steps to generate the simulation model for a PR design:

1. Open the base revision of a PR project in Quartus Prime Pro Edition, and then click **Processing ➤ Start ➤ Start Analysis & Synthesis**. Alternatively, run this command-line equivalent:

```
quartus_syn <project name> -c <base revision name>
```

2. After synthesis is complete, click **Project ➤ Export Design Partition**, and then select the **root partition** for the **Partition name**, and select **synthesized** for the **Snapshot**. Click **OK**. Alternatively, run this command-line equivalent:

```
quartus_cdb <project name> -c <base revision name> \
     "--export_block root_partition --snapshot synthesized \
     --file <static qdb name>
```

3. Click **Project ➤ Revisions** and switch the current revision to that of the persona you want to export.
4. Click **Processing ➤ Start ➤ Start Analysis & Synthesis**. Alternatively, run this command-line equivalent:

```
quartus_syn <project name> -c <persona revision name>
```

5. After synthesis of the persona revision completes, execute the following at the command line to generate the PR simulation model:

```
quartus_eda <project name> –c <persona revision name> "--pr --simulation \
     --tool=modelsim --format=verilog --partition=<pr partition name> \
     --module=<partition name>=<persona module name>
```

6. Repeat steps 3 through 5 for all personas that you want to simulate.

Example 6. Complete PR Simulation Model Generation Script

```
quartus_syn <project name> -c <base revision name>
quartus_cdb <project name> -c <base revision name> \
     "--export_block root_partition --snapshot synthesized \
```

```
     --file <static qdb name>
quartus_syn <project name> -c <persona revision name>
quartus_eda <project name> –c <persona revision name> \
     "--pr --simulation --tool=modelsim --format=verilog \
     --partition=<pr partition name> --module=<partition name>=\
     <persona module name>
```

You can use the PR mode of the EDA netlist writer to generate the gate level netlist of a PR region. Refer to the "EDA Netlist Writer and Gate Level-Netlists" section of the *Quartus Prime Pro Edition User Guide: Third Party Simulation*.

Quartus Prime Pro Edition User Guide: Third Party Simulation

2.8.6. Secure Device Manager Partial Reconfiguration Simulation Model

The Quartus Prime Pro Edition software supports simulating the delivery of a partial reconfiguration bitstream to the Agilex 7, Agilex 5, and Stratix 10 FPGA's secure device manager (SDM).

The SDM is a self-contained system-on-chip that securely manages the boot and configuration process, provides secure key storage, enforces security policies, and provides security services during runtime for Agilex 7, Agilex 5, and Stratix 10 devices. Simulation with the SDM allows you to observe the resulting change and the intermediate effect in a reconfigurable partition.

When you send a simulation RBF (PR bitstream) to the SDM, the SDM can respond with a PR simulation success or PR simulation failure message.

To activate simulation of a specific PR persona in your PR region simulation wrapper, you use a PR ID encoded in the simulation RBF, in conjunction with the SDM.

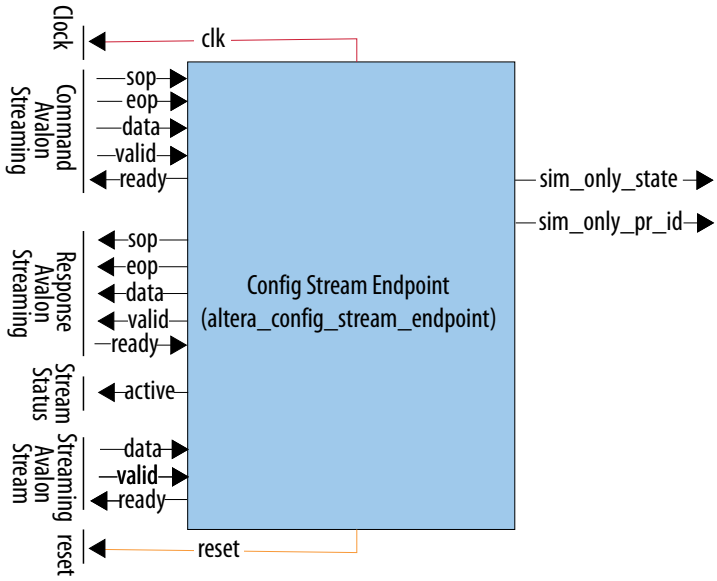
You simulate the SDM as part of the simulation file set for the Partial Reconfiguration Controller Intel FPGA IP and the Partial Reconfiguration External Configuration Controller IP that is available for Agilex 7, Agilex 5, and Stratix 10 devices.

2.8.6.1. Monitoring the SDM

The SDM simulation model exposes the following additional simulation-only ports through the `altera_config_stream_endpoint` module:

- `sim_only_state`
- `sim_only_pr_id`

Figure 93. SDM Partial Reconfiguration Simulation Model - altera_config_stream_endpoint Module



You connect these simulation ports to the `config_stream_endpoint_pr_if` SystemVerilog interface. This connection allows monitoring of the SDM using your testbench's SDM monitor.

The Quartus Prime software automatically instantiates the `config_stream_endpoint_pr_if` interface when generating the simulation file set of the Partial Reconfiguration Controller and the Partial Reconfiguration External Configuration Controller IP.

You can obtain a reference to the `config_stream_endpoint_pr_if` that the IP instantiates by using the following singleton:

```
intel_pr_mailbox_test_pkg::config_stream_endpoint_pr_if_mgr
```

The following example shows this reference:

```
virtual config_stream_endpoint_pr_if pr_mailbox_if

intel_pr_mailbox_test_pkg::config_stream_endpoint_pr_if_mgr pr_mbox_mgr;

// Get the PR Config Stream Endpoint from the pr_mbox manager
pr_mbox_mgr = intel_pr_mailbox_test_pkg::config_stream_endpoint_pr_if_mgr\
   ::get();
pr_mailbox_if = pr_mbox_mgr.if_ref;
```

The following is the code for the `config_stream_endpoint_pr_if` interface:

```
interface config_stream_endpoint_pr_if (input logic clk);
    wire [31:0] sim_only_state;
    wire [31:0] sim_only_pr_id;
endinterface : config_stream_endpoint_pr_if
```

Refer to the following file for more information on the `config_stream_endpoint_pr_if` interface:

```
<installation directory>/eda/sim_lib/altera_lnsim.sv
```

The simulation state of the SDM simulation model represents the PR_EVENT_TYPE enumeration state of the SDM. The `config_stream_endpoint_pr_test_pkg` SystemVerilog package defines these enumerations. These states represent the different allowed states for the SDM. The following are SDM enumeration definitions:

```
package config_stream_endpoint_pr_test_pkg;
    typedef enum logic [31:0] {
        NONE,
        IDLE,
        PR_REQUEST,
        PR_IN_PROGRESS,
        PR_COMPLETE_SUCCESS,
        PR_COMPLETE_ERROR,
        PR_INCOMPLETE_SYS_BUSY,
        PR_INCOMPLETE_BAD_DATA
    } PR_EVENT_TYPE;
```

2.8.6.2. Simulating Unknown Outputs and Persona Activation

To simulate the unknown outputs and persona activation that occurs during the partial reconfiguration process, follow these steps:

1. Ensure that the affected PR region has the simulation output multiplexes driven to X by asserting the `pr_activate` signal when the simulation state is `PR_IN_PROGRESS`.
2. In addition, you must assert the `pr_activate` signal in the PR simulation model to load all registers in the PR model with the PR activation value.
3. Once the simulation state reaches `PR_COMPLETE_SUCCESS`, activate the appropriate PR persona using the appropriate PR region simulation wrapper mux sel signals.
4. Decode the region, as well as the specific select signal from the `sim_only_pr_id` signal of the SDM. This PR ID corresponds to the encoded ID in the simulation RBF.

The SDM simulation model checks encoded instructions in the following simulation RBF locations:

- 1st (`0x97566593`)
- 2nd (`0x4422XXXX`)
- 3rd (`0x5056XXXX`)

If any encoded instructions do not stream into the model in the specified location, the simulation model triggers a PR error, and the error state is reflected in the Partial Reconfiguration Controller Intel FPGA IP or in the Partial Reconfiguration External Configuration Controller Intel FPGA IP.

If the exact number of dummy data that `NNNN` specifies does not stream into the simulation model, the model outputs an info message (`PR warning: Exceed expected length of data!`) to indicate the mismatch number of data sent. No PR error triggers in this case.

2.8.6.3. Simulation RBF Required Word Sequence

The simulation RBF requires the following sequence of words:

RBF Location	RBF Instruction	OpCode	Description
1st	Start of RBF	`97566593`	Identifier word indicates the start of the RBF.
2nd	Expected length (*N*) of data in RBF	`4422NNNN`	Specifies the length of dummy data `NNNN`.
3th	PR region ID (*R*) to activate	`5056RRRR`	Specifies the PR region ID RRRR, which reflects in the `sim_only_pr_id` signal. The PR region ID must be unique, design wide, across all PR partitions.
4th till 4th + `NNNN`	Dummy data	`XXXXXXXX`	Streams `NNNN` number of dummy data into the simulation model. `NNNN` is specified in the 2nd location of the RBF.
4th + `NNNN` + 1	End of RBF	`00001011`	Identifier word that indicates the end of the RBF.

Note: The PR region ID word outputs on the `sim_only_pr_id` word, starting after the first data word. Using a different value for the header or data count results in PR simulation errors.

2.9. Quartus Prime Pro Edition User Guide: Partial Reconfiguration Archive

For the latest and previous versions of this user guide, refer to Quartus Prime Pro Edition User Guide: Partial Reconfiguration. If an IP or software version is not listed, the user guide for the previous IP or software version applies.

2.10. Partial Reconfiguration Solutions IP User Guide Revision History

Document Version	Quartus Prime Version	Changes
2023.04.01	24.1	• Applied initial Altera rebranding throughout. • Updated throughout to reflect support for Agilex 5 devices.
2023.04.03	23.1	• Updated product family name to "Intel Agilex 7." • Added note to *PR Error Recovery* topic about device family support.
2022.01.11	21.4	• Revised *Partial Reconfiguration Controller Intel FPGA IP* section to reflect the new error recovery mechanism that flushes out any remaining corrupted PR bitstream that might be left in user logic pipeline after sending a corrupted bitstream. • Revised Partial Reconfiguration Controller Intel FPGA IP *Parameters* topic for new Enable Protocol Checker and Enable SDM FW Error Reporting parameters that report additional error handshake status and response for detailed error analysis in PR Controller FPGA IP for internal host and debug SDM JTAG command for external host. • Added new *PR Error Recovery* topic. • Added new *PR Error Recovery Timing Specifications* topic. • Added new *Secure Device Manager Firmware Error Reporting* topic. • Added new *SDM Firmware Error Reporting Timing Specifications* topic. • Added new *Partial Reconfiguration External Controller Intel FPGA IP Timing Specifications* topic. • Added new *Secure Device Manager Partial Reconfiguration Simulation Model* section. • Corrected typo in *Agent Interface* topic.
2021.10.04	21.3	• Updated Partial Reconfiguration External Configuration Controller Intel FPGA IP *Ports* topic status bit information. • Updated Partial Reconfiguration Controller Intel FPGA IP *Ports* topic status bit information. • Updated non-inclusive terms with "host" and "agent" for Avalon Memory Mapped interface references throughout.
2021.08.02	21.2	• Updated *Partial Reconfiguration Controller Intel FPGA IP* topic SEU note. • Revised *Register States and Programming Model* figure to correct sequence.
2020.09.28	20.3	• Replaced references to Avalon-MM and Avalon-ST with Avalon memory-mapped and Avalon streaming for legal compliance.
2020.08.07	20.2	• Corrected signal name typos in "Interface Ports" topic for Avalon-MM Partial Reconfiguration Freeze Bridge Intel FPGA IP.
2019.12.16	19.4.0	• Added "Error Detection CRC Requirements" topic.

continued...

Document Version	Quartus Prime Version	Changes
2019.09.30	19.3.0	• Updated the name of "Intel Stratix 10 Partial Reconfiguration Controller FPGA IP" to "Partial Reconfiguration Controller Intel FPGA IP" to encompass support for Agilex 7 devices. • Added note about connection of dummy_clk in "PR Control Block and CRC Block VHDL Module." • Added note to "PR Bitstream Compression and Encryption" topic about support for enhanced decompression.
2019.06.07	19.1.0	• Added note and reference to *Stratix 10 Configuration User Guide*.
2019.04.22	19.1.0	• Indicated support for POF generation support for Intel Cyclone GX devices.
2019.01.04	18.1.0	• Clarified statement about configuration width in "Control Block Signals" topic.
2018.12.07	18.1.0	• Corrected typographical error in "Partial Reconfiguration IP Cores" table. • Corrected typographical error in "Avalon-MM Slave to PR Region Master Interface Ports" table.
2018.09.24	18.1.0	• Updated specification for Partial Reconfiguration Controller Stratix 10 FPGA IP from 250 MHz to 200 MHz. • Stated PR compilation flow support for Cyclone 10 GX devices. • Updated Partial Reconfiguration Controller Arria 10 FPGA IP name to Partial Reconfiguration Controller Arria 10/Cyclone 10 FPGA IP.
2018.06.27	18.0.0	Updated `freeze_status` signal description in *Registers: Partial Reconfiguration Region Controller*.
2018.06.18	18.0.0	• Corrected syntax error in *Generating the PR Persona Simulation Model*.
2018.05.07	18.0.0	• Added description of new Partial Reconfiguration External Configuration Controller Stratix 10 FPGA IP. • Updated names of Partial Reconfiguration Controller Arria 10 FPGA IP and Partial Reconfiguration Controller Stratix 10 FPGA IP. • Enhanced explanation of **Auto-instantiate CRC block** Partial Reconfiguration Controller Arria 10 parameter. • Added as chapter in new *Partial Reconfiguration User Guide*. • Added note about recovery after PR error when using SEU detection in Stratix 10 designs.
2017.11.06	17.1.0	• Added support for Stratix 10 Partial Reconfiguration Controller IP core. • Updated for latest Intel product naming conventions.
2017.05.08	17.0.0	Initial public release.

A. Quartus Prime Pro Edition User Guides

Refer to the following user guides for comprehensive information on all phases of the Quartus Prime Pro Edition FPGA design flow.

Related Information

- Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Quartus Prime Pro Edition software, including managing Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys* that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys*. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

Answers to Top FAQs:

Contents

1. FPGA Simulation Basics

This chapter is a high-level explanation of FPGA simulation basic concepts and workflows for all simulators that the Quartus® Prime software supports. An understanding of these basic concepts provides a foundation for performing simulation using your supported simulator of choice.

While the details of using a particular simulator vary, the basic foundational concepts and tasks of FPGA design simulation are common to all supported simulators.

Related Information

Supported Simulators on page 19

1.1. FPGA Simulation Essential Elements

The following describes the essential elements required for FPGA design simulation.

Design

An Quartus Prime design typically consists of a top-level design module containing a hierarchy of module instances, defined in one or more HDL files. The design that you intend to simulate is known as the Design Under Test (DUT).

Testbench

To simulate the DUT (that is, a design), you must also provide a separate HDL module (referred to as the testbench module) that instantiates the DUT and additional logic to stimulate the DUT and to capture the output from the DUT. The testbench module can include a hierarchy of module instances related to the testbench, but that are not part of the design. You define the testbench modules in one or more HDL files.

Top-Level Testbench

A top level testbench module is the testbench module that instantiates all other design and testbench related modules. This is the module you simulate.

HDL Design and Testbench Files

Simulating a design requires HDL design files, and one or more HDL testbench files. Quartus Prime designs typically consist of several modules that you define in multiple HDL files. These files can include HDL files generated by Quartus Prime tool, such as Quartus Prime Platform Designer.

Some of the modules instantiated in the design may be common to many designs. Examples of some common modules are low-level primitives, like AND and OR gates, and more complex blocks, such as multipliers and FIFOs.

The low level modules common to many designs are known as *simulation library modules*, and the files defining those modules are known as *simulation library files*. The Quartus Prime software installation provides various simulation library files, as The Quartus Prime Simulation Library describes.

The combination of design and testbench files includes all the modules that are instantiated in the top-level testbench module hierarchy, including all of the modules for the design, because the design is instantiated within the testbench hierarchy.

Executable Simulation Model

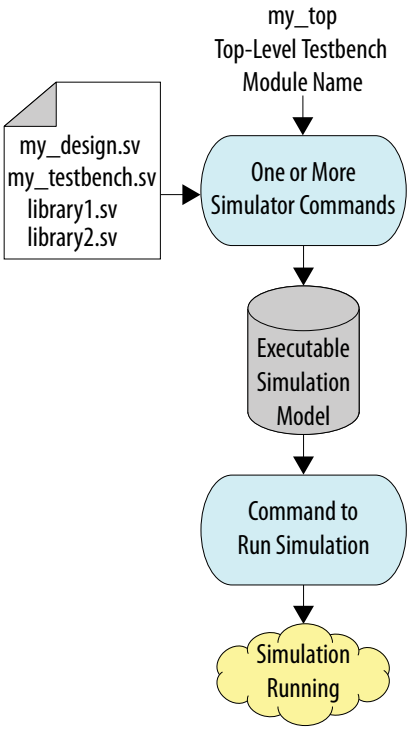
In order to simulate a design you must first generate an executable simulation model of the top-level testbench by running a set of simulator specific commands. You must then run the executable model to perform simulation. Running the executable model may require simulator specific commands. The executable model is typically a set of binary files specific to a simulator.

Simulator Commands

You must run one or more simulator commands to generate the executable simulation model and then to run the executable simulation model. The commands require the following inputs to generate an executable model of the top-level testbench module that you can simulate, as the Inputs and Commands to Generate and Run the Executable Model figure shows:

- The name of the top-level testbench module.
- The HDL design files, including files generated by tools such as Platform Designer, simulation library files, and testbench files.

Figure 1. Inputs and Commands to Generate and Run the Executable Simulation Model



Since you must run several commands to create and run the executable model to perform simulation, you can place the calls to the commands into one or more simulation scripts for convenience. These scripts can be Linux shell scripts, Tcl scripts, Perl, or Python scripts.

1.2. Overview of Simulation Tool Flow

The various simulator commands that you use to generate and run the executable model are all part of the simulation tool flow. A simulation tool flow consists of executing the following three stages of the simulation, in that order:

1. Compilation
2. Elaboration
3. Simulation

You run simulator specific commands at each stage in the flow.

1.2.1. Compilation Stage

In the first stage of simulation you run compilation commands.

Inputs to a Compilation Command

The compilation command takes as input one or more design files, testbench files, and simulation library files.

What Does a Compilation Command Do?

A compilation command does the following:

1. Reads the files that you specify as arguments to the command.
2. Analyzes the content of the files, which includes checking for syntax errors and other issues.
3. Stores the analyzed content (such as the module definitions) in a directory in a simulator specific proprietary format. The directory is known as a library directory. You can also specify the directory as an input argument.

   This step of storing the analyzed content of HDL files in a library directory is known as *compiling the files into a library directory*, or simply *compiling a file*.

Compiling a file is similar to running Quartus Prime Analysis & Synthesis, in that the analyzed file content is stored in design database directory. The compilation is also loosely analogous to compiling a C/C++ file into an object file, where the object file is stored in a separate directory.

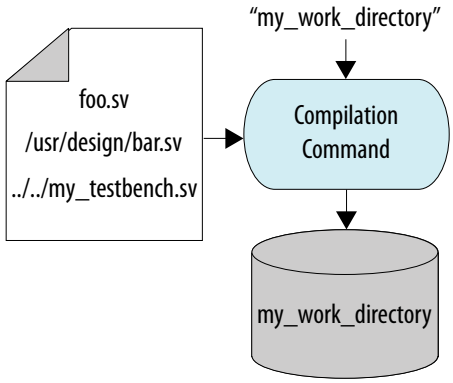
The library directory contains the definitions of all modules that are defined in the files that you compiled into the library. You use these module definitions in the elaboration stage. You may need to run multiple compilation commands to compile all the files into library directories.

Compilation Command Example

Consider a design example that has two design files, `foo.sv` and `bar.sv`, and one testbench file, `my_testbench.sv`.

To compile these files, you first create a new directory, for example `my_work`. Next, you run the simulator specific compilation command that takes in the file names and directory name as inputs, as the File and Directory Name Input to Simulator Specific Compilation Command figure shows. Once the command runs successfully, one or more files appear in the `my_work` library directory. The directory contains the definitions of all modules the three HDL files define, in a proprietary format that only the simulator understands.

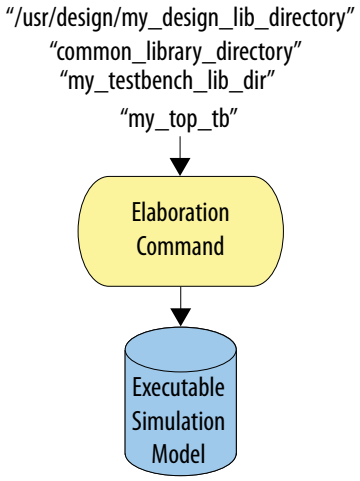
Figure 2. File and Directory Name Input to Simulator Specific Compilation Command



1.2.2. Elaboration Stage

The elaboration stage follows the compilation stage. In the elaboration stage you typically run just one elaboration command. This elaboration command can take several inputs. At the minimum, elaboration requires as input the top-level testbench module name, and the list of library directories that the compilation stage creates.

Figure 3. Elaboration Stage Inputs and Output



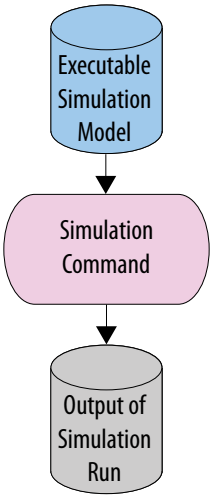
The output of the elaboration command is the executable simulation model for the top-level testbench. The executable simulation model comprises one or more simulator-specific files and directories. For more details about the elaboration stage, refer to Understanding Elaboration.

1.2.3. Simulation Stage

The commands that apply to the simulation stage actually run the simulation. The input to simulation stage commands is the executable simulation model that you generate during the elaboration stage, along with other inputs, such as how long to simulate, and which signals to capture for waveform viewing and dumping.

As the Files and Directories for Executable Model of my_top_tb figure shows, the output of the simulation stage is simply the output from a simulation run, which can include messages issued by HDL modules, files written out by the simulator such as waveform dumps, and any GUI display of simulation in progress.

Figure 4. Files and Directories for Executable Model of my_top_tb



1.3. Simulation Tool Flow

The simulation tool flow begins with the compilation stage that compiles files into logical libraries using simulator specific compilation commands.

The next stage is elaboration, where you run the elaboration command to generate an executable simulation model. In the final stage, you run the executable simulation model to run the simulation.

The following topics describe these simulation tool flow concepts in more detail:

1. Specifying Logical Libraries
2. Compiling Files into Library Directories
3. Understanding Elaboration
4. Commands to Configure and Run Simulation

1.3.1. Specifying Logical Libraries

Some simulator commands for compilation and elaboration require you to specify a *logical library* name as input.

A *Logical library* is simply a name (typically short and readable) that represents a physical library directory. For example, logical library name `foo` can represent physical directory `/users/jsmith/design1/bar`. The simulator commands translate the logical library name to a physical directory name by reading in a library mapping file. The simulator commands require only the physical directory names.

The mapping of logical library names to physical directory names is known as *library mapping*, which you must define. You typically store the library mapping in a separate text file in a proprietary text format, with each line containing a single logical library name and the corresponding library directory path. You can either update the file manually, or by using a simulator specific command (if available). This library mapping file often has a fixed simulator specific name and a fixed location. Therefore, you do not generally specify the library mapping file as an argument to simulator commands, even though the file is read by the commands.

A logical library name is an optional argument to many simulator commands. If you do not specify a logical library name for such commands, the default value is `work`. Therefore, you must map the logical library name `work` to a physical directory name. Some simulators add a default library mapping for the `work` library if you do not specify a mapping in a library mapping file. It is legal to map multiple logical library names to a single library directory.

Example library mapping file with logical library names `foo_lib` and `common_sim_lib`:

```
foo_lib  :   /users/john/designs/foo_dir
common_sim_lib  : /usr/sim/common/libraries
```

Note: syntax of library mapping file varies with simulator

1.3.1.1. Why Do We Need Logical Library Names?

Using logical library names instead of physical directory names in command invocations and in HDL files (especially VHDL files) simplifies some aspects of simulation. Use of logical library names makes it easier to port simulation scripts when moving the scripts across machines and disks because you only need to update the library mapping to reflect any new library directory paths in the new environment.

For example, Intel recommends compiling Quartus Prime simulation library files into fixed logical library names. You can then map the logical library names to appropriate library directory paths.

1.3.2. Compiling Files Into Library Directories

Many simulators include commands to compile one or more files, specified in some order, into a single library directory. You specify the library directory by specifying its logical library name. Some simulators have one command for compiling Verilog HDL or SystemVerilog files, and a different command for compiling VHDL files.

The following section describes the various commands for compiling files into library directories.

1.3.2.1. Inputs to Compilation Commands

Compilation commands accept the following inputs:

- An ordered list of one or more HDL file names, usually file names separated by spaces.

  Note: The file order is important in some cases, as Order of Files for Compilation Commands explains.
- (Optional) Command line options to configure the compilation behavior, as Compilation Command-Line Options describes.
- (Optional) The name of the logical library or a library directory name. When not specified, the logical library default value is the `work` library, as Specifying Logical Libraries describes.

Note:

1. You can compile two or more files using a single compilation command if you can compile them into the same library, and they require the same compilation options. The compilation command can take a list of HDL files as input.
2. You can compile files defining modules that are not part of the design or testbench. The elaboration stage ignores such modules. In fact, in practice, you typically compile many more modules than are required to simulate the top-level testbench module.

The compilation command generates outputs, as Compilation Stage describes.

1.3.2.2. Order of Files for Compilation Commands

The order of files that you specify to compilation commands is irrelevant for Verilog and SystemVerilog files in many instances. The main exception is when there are files defining SystemVerilog packages, or other files that import or otherwise refer to those SystemVerilog packages.

Important: You must compile the files defining the SystemVerilog packages before compiling the files that import or refer to those packages. Otherwise, the compilation command errors out when compiling files that import or refer to those SystemVerilog packages.

For example, suppose file `multp_pkg.sv` defines the SystemVerilog package `multp`, and the file `my_design.sv` imports package `multp`:

- If you compile both `multp_pkg.sv` and `my_design.sv` with a single compilation command, you must ensure that `multp_pkg.sv` occurs before `my_design.sv`.
- If you compile `multp_pkg.sv` and `my_design.sv` using separate compilation commands, you must ensure that you run the command that is compiling `multp_pkg.sv` first.

VHDL has stricter requirements for ordering the files. For example, when a VHDL file `foo.vhd` refers to a logical library name `lib1`, you must compile the files into `lib1` first, before compiling `foo.vhd` into another library.

1.3.2.3. Compilation Command Line Options

Some of the optional command-line arguments for the compilation command (not including HDL file names and library names) include:

- The type of file for compilation (Verilog HDL, SystemVerilog, or VHDL).
- The values of the Verilog macros to pass in.
- The directories containing Verilog "include" files. These are files included in a Verilog HDL file using the `` `include `` construct.
- Simulator-specific optimization switches.

1.3.2.4. Module Definitions in Library Directories

A library directory can contain one or more module definitions, as well as other elements, such as SystemVerilog package definitions.

A library directory can store only one module definition per module. For example, if the `adder.sv` and `adder_fast.sv` files define the same module `adder`, but have different implementations (perhaps `adder_fast.sv` implements a fast adder), then compiling both files into the same library directory with a single compilation command results in a compilation error. However, you can compile the `adder.sv` and `adder_fast.sv` files into different library directories.

You can also replace an existing module definition in a library with another module definition with the same module name. For example, if a library directory already includes a module definition for `adder` (from compiling file `adder.sv`), and you compile the `adder_fast.sv` file into that library directory, the existing module definition in the library directory is replaced with the module definition from `adder_fast.sv`.

1.3.3. The Quartus Prime Simulation Library

The Quartus Prime software includes the Quartus Prime simulation library. This library is comprised of Verilog HDL and VHDL files in the following directory:

```
<quartus_installation>/quartus/eda/sim_lib
```

This library includes simulation models for all low-level blocks that you instantiate in your design. The library includes the following different types of low level blocks:

Table 1. Low Level Blocks in Simulation Library

Low-Level Blocks	Description
Gate-Level Primitives	Gate-level primitives include simple, non-parameterized modules, such as AND gates and flip-flops. `altera_primitives.v` and `altera_primitives.vhd` define the gate-level primitives. These primitives are only used in RTL designs. Post-synthesis and post-fit netlists do not include these primitives. Rather, these netlists include ATOMs.
Basic IP Function Blocks	Previously known as "megafuctions," these are basic parameterized blocks for functions such as FIFOs and multipliers. Only RTL designs use these blocks. Post-synthesis and post-fit netlists do not include these blocks.
ATOMs	Also known as WYSIWYGs, ATOMs are the lowest level primitives in an Quartus Prime design. There are different ATOM primitives, all of them parameterized modules with varying complexity. They represent the hardware blocks on the FPGA. For example there are ATOM modules that represent the I/O pins and buffers, FPGA lookup tables, DSP blocks, RAM blocks, and periphery

continued...

Low-Level Blocks	Description
	blocks, such as high speed transceivers and hardened Ethernet and PCIe blocks. You are not expected to instantiate ATOMs directly in your RTL. Rather, the ATOMs are instantiated in the RTL files that the Quartus Prime software generates. Since the Quartus Prime synthesis maps the design to ATOMs, the post-synthesis and post-fit netlists are netlists of ATOMs, known as ATOM netlists. The Fitter places and routes the ATOM netlist.
HDL Library Files	You compile the HDL library files into fixed logical locations, as Compiling Files into Library Directories describes. You must not compile the libraries for Questa* Intel® FPGA Edition. Instead use the included precompiled libraries.

1.3.3.1. The Quartus Prime Simulation Library Compiler

The Quartus Prime Simulation Library Compiler is an Quartus Prime software GUI and command-line tool that generates simulation scripts. You can use these scripts to automatically compile the Quartus Prime software simulation libraries for a given simulator, device family, and hardware description language (Verilog HDL or VHDL).

Note: For Questa Intel FPGA Edition, do not use the Simulation Library Compiler to compile the libraries in Questa Intel FPGA Edition. Instead, you must use the Questa Intel FPGA Edition precompiled libraries included with this simulator.

Related Information

Questa Intel FPGA Edition Simulation User Guide

1.3.3.2. Running the Simulation Library Compiler in a Terminal

You can run the Quartus Prime Simulation Library Compiler in a terminal without launching the Quartus Prime software GUI.

The following example command generates the Questasim `compile.do` simulation script that compiles all Verilog HDL simulation files for the specified Agilex™ 7 device family.

```
quartus_sh –simlib_comp -family agilex7 -tool questasim \
     -language verilog -gen_only -cmd_file compile.do
```

To view all available command-line options, you can run the following command:

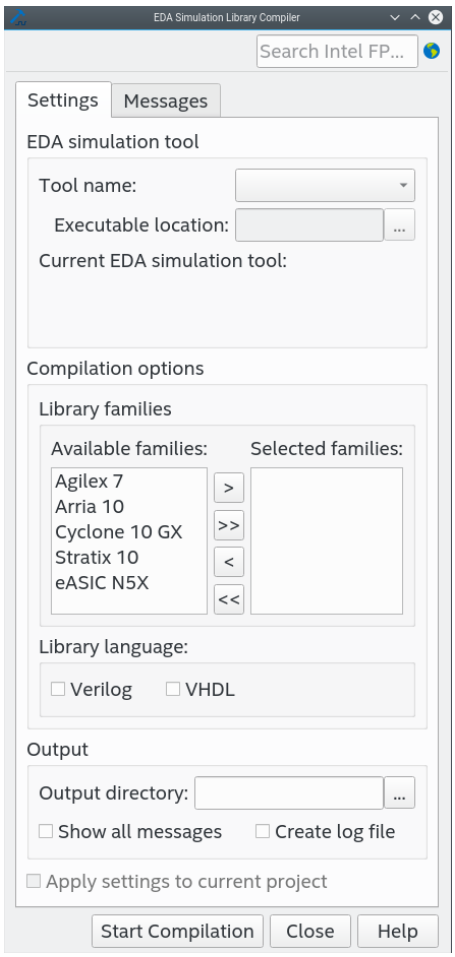
```
quartus_sh --help=simlib_comp
```

1.3.3.3. Running the Simulation Library Compiler in the GUI

To automatically compile all required simulation model libraries for your design in your supported simulator using the Simulation Library Compiler GUI, follow these steps:

1. In the Quartus Prime software, click **Tools ➤ Launch Simulation Library Compiler**.
2. Specify options for your simulation tool, language, target device family, and output location, and then click **OK**. Simulation model compilation may require up to an hour, depending on your system. Although the compilation messages may appear paused or incomplete, compilation is still running correctly.
3. Use the compiled simulation model libraries to simulate your design. For information about running simulation, refer to your supported EDA simulator's documentation.

Figure 5. Simulation Library Compiler GUI



1.3.3.4. Finding Logical Library Names in Simulation Library Compiler Output

After you generate the simulation script using the Simulation Library Compiler, you may need to inspect the script to identify the logical library names for use with your elaboration command (`vsim`).

To identify the logical library names for Quartus Prime simulation libraries in the generated script, search for all of the lines that begin with `vmap`, such as the following line:

```
vmap altera_ver "./verilog_libs/altera_ver"
```

The first argument to `vmap` is the logical library name (`altera_ver`). The second argument is the physical directory where the library content is stored. This second argument is irrelevant for Questa Intel FPGA Edition because you do not run the command.

1.3.4. Understanding Elaboration

Simulator elaboration is analogous to the linking step in C/C++ programming that produces an executable binary file.

You can run elaboration with a single command that accepts the following inputs and generates an executable model for the top-level testbench module name:

- An ordered list of logical library names. You can specify the ordered list of logical library names either explicitly on the elaboration command line, or by ordering them in the library mapping file. If reading from the library mapping file, the simulator uses the order of logical libraries in the library mapping file.
- (Optional) Elaboration options.
- Top-level testbench module name.
- (Optional) The name of the logical library containing the top-level testbench module definition. If omitted, the top-level testbench module defaults to the `work` library.

The elaboration command does not read any HDL files. The elaboration command only reads the library directories containing the module definitions.

An important part of elaboration is to find the module definitions for all the module instances in the top-level testbench module hierarchy. This identification is described as binding the module instances to their module definitions, or linking the module instances to their module definitions. Understanding the binding process during elaboration is important when debugging common elaboration errors, as Elaboration Binding Phase describes.

1.3.4.1. Elaboration Binding Phase

Elaboration works in a top-down manner to bind module instances in the following order:

1. Elaboration finds the top-level testbench module definition, given the module name and the library that contains the module definition as input. Typically, you compile the top-level testbench module into the `work` library. For example, specifying the top-level testbench module as `foo` with no library name, is equivalent to specifying the top-level testbench module as `work.foo`.
2. Elaboration reads the module definition, and identifies all the module instances in the top-level testbench module.
3. Elaboration attempts to find the module definitions for all instances in the top-level testbench, one instance at a time.

   For example, for an instance `inst1` of module `foo` in the top-level testbench module `tb`, elaboration attempts to find the definition of module `foo` by searching for `foo` in the first library in the ordered list of library directories. If elaboration cannot find the module definition in the first library directory, it searches in the second library directory, and so on.

   Once elaboration finds the definition of `foo` in a library directory, it stops searching for the definition. Therefore, if `foo` is defined in multiple library directories, elaboration uses only the first instance, and ignores any other instances. In this way, elaboration binds `inst1` to `foo`.

4. Elaboration attempts to find all of the module instances within `foo`, and then to find the module definitions for those instances using the same process that elaboration followed for binding `foo`.
5. Elaboration recursively attempts to bind all the module instances within the `foo` module's hierarchy before processing other instances in the top-level testbench `tb`.
6. The elaboration stage ends in one of the following ways:
   - All instances in the top-level testbench hierarchy are bound to modules, and elaboration succeeds.
   - An error is generated because elaboration cannot bind one or more instances in the top-level testbench module hierarchy to modules.

1.3.4.2. Elaboration Checks

The elaboration command performs several checks. For example, elaboration verifies that the module definitions are consistent with their instantiations. This check confirms that a module's ports and parameter definitions match the corresponding module instances.

1.3.4.3. Elaboration Options

There are many simulator specific elaboration options that you can specify. One common elaboration option preserves specific signal names so that their waveforms (a record of how the signals change with time) can be recorded during simulation. The rationale behind this option is explained below.

The elaboration stage generally includes an optimization step. The optimization step attempts to build an optimized executable simulation model that can run faster or consume less memory during simulation.

There are many signals (defined as wire, reg, or logic variables) in a typical design and testbench hierarchy. At the end of a simulation, any signal can produce a simulation waveform.

The optimization step may be unable to fully optimize the executable simulation model if most of the signals in the testbench hierarchy are preserved. Therefore, it is best to limit the signals that you preserve to those that require waveforms during simulation. You can specify the signals to preserve at varying level of granularity. For example, you can specify specific signal names, or all signals within a module instance.

1.3.5. Commands To Configure and Run Simulation

Once you generate the executable simulation model during elaboration, you can run the executable simulation model to simulate the top-level testbench module.

There are several different methods to configure and run simulation. The following are some of the typical simulator commands and options that you can use for simulation:

- You can specify which signals that you want the simulator to record during simulation. You must ensure that those signals are preserved during the elaboration stage, as Elaboration Options explains.

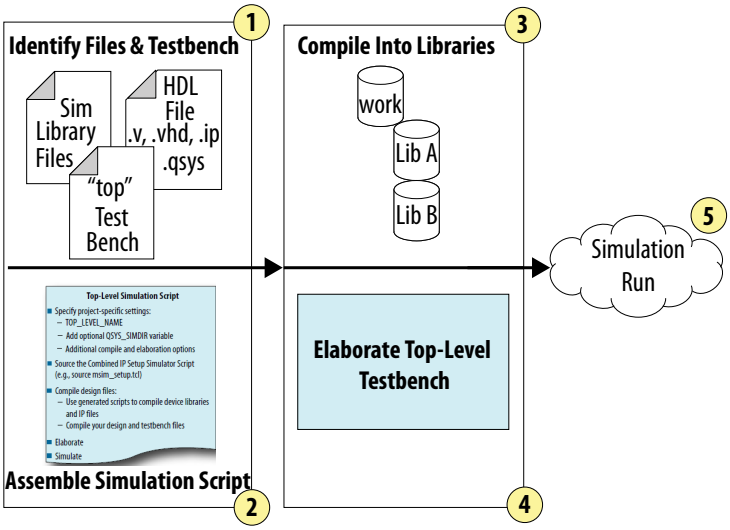
  The simulator writes the waveforms of these signals to a simulator proprietary database during simulation. You can view the waveforms in a GUI after simulation.

  Note: You cannot record or display signals in encrypted HDL files with the simulator.
- You can specify the amount of simulation time to simulate the top-level testbench module. For example, you can specify a simulation time of 1 milliseconds.
- You can specify an option to wait for simulation licenses. This option is applicable when using floating simulation licenses. Some simulators exit immediately if there are no available floating licenses for simulation.

1.3.6. FPGA Simulation Generic Workflow

The following describes the high level workflow for simulation of any Quartus Prime design using any supported simulator:

Figure 6. Generic FPGA Simulation Workflow



1. Identify all of the HDL simulation files, including design files, simulation library files, and HDL testbench files.
2. Identify the top-level test bench module for simulation.
3. For each HDL simulation file, determine the logical library for compilation, and any compilation options for compiling the file.(1)
4. Determine any simulator-specific elaboration options required for elaborating the top- level testbench module, as Understanding Elaboration describes.
5. Use the information gathered in previous steps to assemble a simulation script to compile, elaborate, and simulate the design. This script must include commands to perform the following:

- Compile the simulation files into libraries, as Compiling Files into Library Directories describes.
- Elaborate the Top-Level testbench, as Understanding Elaboration describes.
- Run the executable simulation model to simulate the testbench and the design, using the appropriate commands for your simulator to configure and run simulation.

The Quartus Prime software can generate simulator-specific simulation scripts to automate some of the simulation processing in your preferred simulation environment.

The Quartus Prime software can generate a simulator specific simulation script for an IP core, or a Platform Designer system, for use in RTL simulation. The script includes commands to compile all the IP RTL files, as well as an elaboration command with any simulator specific options.

The Quartus Prime software can generate a simulation library compilation script for a given simulator, device family, and language. This script includes commands to compile the simulation library files for the specified simulator, device family, and language. You can use this script for RTL simulation and gate-level simulation.

1.4. Supported Simulation Flows

The Quartus Prime software supports scripted and specialized simulation flows.

Table 2. Simulation Flows

Simulation Flow	Description
Scripted Simulation Flows	Scripted simulation supports custom control of all aspects of simulation, such as custom compilation commands, or multipass simulation flows. Use a version-independent top-level simulation script that sources Quartus Prime-generated IP simulation setup scripts. The Quartus Prime software can generate a combined simulator setup script for all IP cores, for each supported simulator.
Run Simulation	You can use the Run Simulation feature in the Quartus Prime Pro Edition software to integrate your supported third-party EDA simulator and automate generation of simulator-specific files and setup scripts, compilation of simulation libraries, and launch of your simulation.
Qrun Flow	The Qrun flow optionally creates simulation files, including the functional simulation model, and any testbench (or example design) for the QuestaSim* and Questa Intel FPGA Edition simulators only. The Qrun flow can automatically combine the compile, optimize, and simulate functions into a single step.
Specialized Simulation Flows	Specialized simulation flows support various design scenarios: • For simulation of example designs, refer to the example design pr IP documentation. • For simulation of Platform Designer designs, refer to *Simulating Platform Designer Systems* in *Quartus Prime Standard Edition User Guide: Platform Designer*. • For simulation of the Nios® V processor, refer to the *Nios V Embedded Processor Design Handbook*.

1.5. Supported Hardware Description Languages

The Quartus Prime software provides the following hardware description language (HDL) support for EDA simulators.

(1) In general, you can compile most HDL simulation files into the default work library.

Table 3. HDL Support

Language	Support Description
VHDL	• For VHDL simulation, you compile design files, testbench files, and Platform designer generated RTL files using simulator commands. • For all supported simulators other than Questa Intel FPGA Edition, you must also compile simulation models from the Quartus Prime simulation libraries. • Many of the Quartus Prime simulation models and IP RTL files are implemented in Verilog or SystemVerilog only. Therefore, you may require a simulator that is capable of VHDL and Verilog HDL mixed language simulation.
Verilog / SystemVerilog	• For Verilog or SystemVerilog simulation, you compile design files, testbench files, and Platform Designer generated RTL files using simulator commands. • For all supported simulators other than Questa Intel FPGA Edition, you must also compile simulation models from the Quartus Prime simulation libraries. • There are some IP RTL files that are implemented in VHDL only. Therefore, you may require a simulator that is capable of VHDL and Verilog HDL mixed language simulation.
Mixed HDL	• If your design is a mix of VHDL, Verilog HDL, and SystemVerilog files, you must use a mixed language simulator. • The Questa Intel FPGA Edition software supports native, mixed-language (VHDL/Verilog HDL/SystemVerilog) simulation. If you have a VHDL-only simulator and need to simulate Verilog HDL modules and IP cores, you can either acquire a mixed-language simulator license from the simulator vendor, or use the Questa Intel FPGA Edition simulator.
Schematic	• You cannot simulate a schematic in any of the simulators that the Quartus Prime software supports. • To perform RTL simulation of the schematic, you must convert the schematic to HDL format and run RTL simulation on the HDL. The Quartus Prime Pro Edition software cannot perform schematic conversion. • To perform post-synthesis or post-fit simulation, you must first compile the schematic based design in the Quartus Prime software, generate a gate-level Verilog HDL or VHDL simulation netlist, and perform simulation on the gate-level netlist.

1.6. Supported Simulation Types

You can run different types of simulation, depending on the stage of the Quartus Prime design flow:

Table 4. Supported Simulation Types

Simulation Type	Description	Occurs
RTL	Simulation of an RTL design consisting of one or more RTL files that you provide as input to the Quartus Prime software. These RTL files typically also include the files that the Quartus Prime Platform Designer generates for Intel FPGA IP and systems. You can only simulate HDL RTL files.(2). The RTL files can instantiate low level blocks, such as primitives, basic IP functions, and ATOMs, as Intel Quartus Prime Simulation Library describes.	Can perform before Quartus Prime Synthesis
Post-Synthesis Simulation (Gate-Level)	The Quartus Prime software can generate a Verilog HDL or VHDL gate-level netlist after the synthesis stage completes, but before the Fitter stage runs. The resulting netlist is the post-synthesis netlist. The	Must perform after Quartus Prime synthesis

continued...

(2) You must first convert the non-HDL files to HDL files prior to simulation

Simulation Type	Description	Occurs
	Quartus Prime EDA Netlist Writer tool generates the post-synthesis netlist. The post-synthesis netlist is a netlist of low level blocks called ATOMs. The post-synthesis netlist is a purely functional netlist.	
Post-Fit Simulation (Gate-Level)	The Quartus Prime EDA Netlist Writer can generate a Verilog HDL or VHDL gate-level netlist after the Fitter stage completes. The resulting netlist is the post-fit netlist. The post-fit netlist is a netlist of ATOMs that the Fitter placed and routed on the FPGA device. The post-fit netlist is a purely functional netlist. *Note:* The post-fit netlist includes chip locations of ATOM instances in commented lines. The post-synthesis netlist does not include this data.	Must perform after Quartus Prime Fitter

Note: the Quartus Prime software supports post-fit functional simulation, but does not support post-fit timing simulation.

1.7. Supported Simulators

The Quartus Prime software supports the following EDA simulator versions for RTL and gate-level simulation.

Table 5. Quartus Prime Pro Edition Supported Simulators

Vendor	Simulator	Version	Platform	Supports Siemens EDA Verification IP
Aldec	Active-HDL*	14.0	Windows* 64-bit	No
Aldec	Riviera-PRO*	2023.10	Windows, Linux, 64-bit	No
Cadence	Xcelium* Parallel Simulator	23.09.004	Linux 64-bit	Yes
Altera	Questa Intel FPGA Edition	2023.4	Windows, Linux, 64-bit	Yes
Siemens EDA	QuestaSim Simulator(3)	2023.4	Windows, Linux, 64-bit	Yes
Synopsys*	VCS*, VCS MX	U-2023.03-SP2-1	Linux 64-bit	Yes

Table 6. Quartus Prime Standard Edition Supported Simulators

Vendor	Simulator	Version	Platform
Aldec	Active-HDL	14.0	Windows
Aldec	Riviera-PRO	2023.04	Windows, Linux
Cadence	Xcelium	23.03.003	Linux
Altera	Questa Intel FPGA Edition	2023.3	Windows, Linux
Siemens EDA	QuestaSim	2023.2	Windows, Linux
Synopsys	VCS VCS MX	U/2023.03-1	Linux

(3) QuestaSim is the generic name for Questa Core and Questa Prime simulators from Siemens EDA.

Related Information

- Questa Intel FPGA Edition Simulation User Guide
- IBIS Models for Intel FPGA Devices

1.8. Post-Fit Simulation Support by FPGA Family

The current version of the Quartus Prime Pro Edition software provides the following post-fit functional simulation support per FPGA family. In the table, Core fabric is the main FPGA die that includes lookup tables, M20K memories, and DSP blocks. Basic I/Os do not include complex interfaces, such as transceivers or external memory interfaces.

Table 7. Post-Fit Simulation Support by FPGA Family

FPGA Family	Post-Fit Simulation Support Level
Agilex 7 F-Series FPGAs	Limited support for designs that contain only core fabric logic and basic I/Os.
Agilex 7 M-Series FPGAs	Limited support for designs that contain only core fabric logic and basic I/Os.
Agilex 7 I-Series FPGAs	Limited support for designs that contain only core fabric logic and basic I/Os.
Stratix® 10 FPGAs	Limited support for designs that contain only core fabric logic and basic I/Os.
Cyclone® 10 GX FPGAs	Limited support for designs that contain only core fabric logic and basic I/Os.
Arria® 10 FPGAs	Limited support for designs that contain only core fabric logic and basic I/Os.

Note: For more information, refer to the specific FPGA device user guide.

1.9. Automating Simulation with the Run Simulation Feature

You can use the Run Simulation feature in the Quartus Prime Pro Edition software to integrate your supported third-party EDA simulator and automate the following steps of the simulation flow:

- Automatic generation of simulator-specific files and setup scripts.
- Automatic compilation of simulation libraries.
- Automatic launch of your simulator after running Quartus Prime Analysis & Elaboration.

You can use the simulation scripts that Run Simulation generates as a starting point to create more custom simulation scripts that may be required for large or complex FPGA designs.

Note: The current version of the Quartus Prime Pro Edition software supports the Run Simulation feature for only RTL simulation, not gate-level simulation.

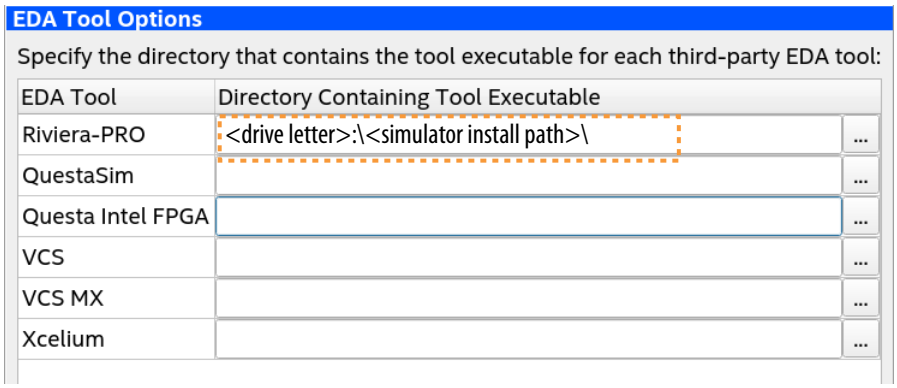
1.9.1. Setting Up the Run Simulation Feature

You must first setup the Run Simulation feature before using it to automate portions of the simulation flow.

To setup the Run Simulation feature by specifying the settings that identify your simulator, output path, and other options, follow these steps:

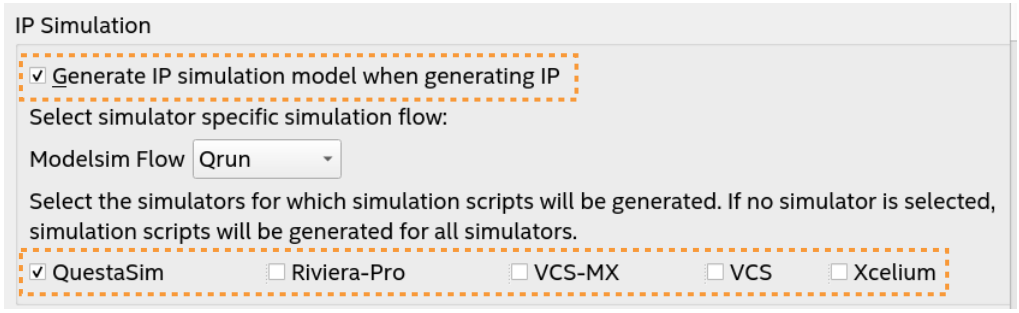
1. Open a project in the Quartus Prime software.
2. Click **Tools ➤ Options ➤ EDA Tool Options** and specify the location of your simulator executable file, as Execution Paths for Supported EDA Simulators describes in detail.

Figure 7. Specifying Simulator Install Path



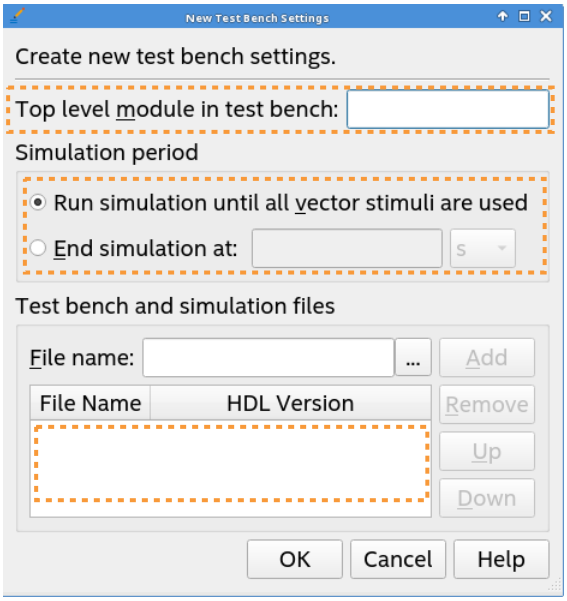
3. To enable automated generation of the IP simulation models whenever you generate HDL for IP in Platform Designer, click **Tools ➤ Options ➤ Board and IP Settings ➤ IP Simulation**. Make sure **Generate IP simulation model when generating IP** option is turned on, as Simulation Options describes in detail.

Figure 8. Specifying Automated IP Simulation Model Generation



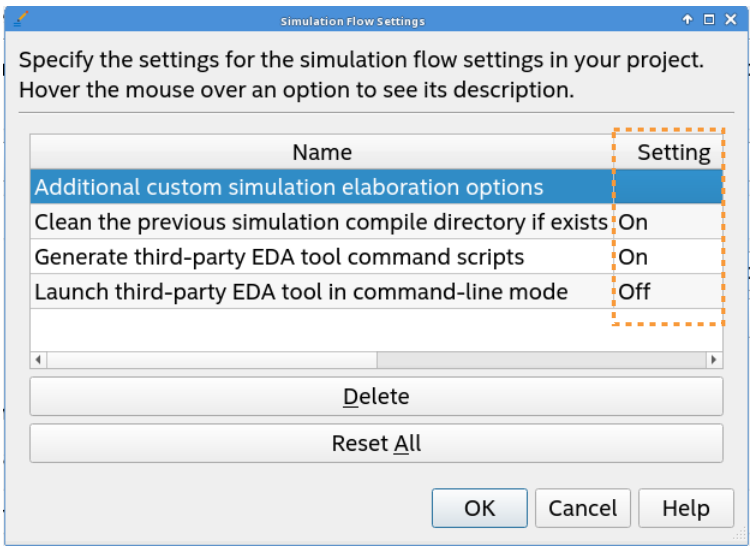
4. Click **Assignments ➤ Settings ➤ EDA Tool Settings ➤ Simulation** and specify the following simulation settings:
   a. For **Testbench Specification**, click the **New** button and enter the testbench information, including the **Top level module in testbench**, **Simulation period**, and **Testbench and simulation files** options.

Figure 9. Defining Testbench Specification



b. Click the **Simulation Flow Settings** button to specify additional options for the automated simulation flow, as Simulation Flow Settings describes in detail.

Figure 10. Simulation Flow Settings



1.9.1.1. Installation Paths for Supported EDA Simulators (EDA Tool Options Page)

The following are execution paths for supported EDA simulators. Click **Tools ➤ Options ➤ EDA Tool Options** to specify the execution path to automatically launch your simulator.

Table 8. Installation Directory Paths for Supported EDA Simulators

Simulator	Path
Questa Intel FPGA Edition	Windows: *<drive letter>*:*<simulator install path>*\ Linux: *<simulator install path>*/
Siemens EDA QuestaSim	Windows: *<drive letter>*:*<simulator install path>*\ Linux: *<simulator install path>*/
Synopsys VCS/VCS MX(4)	Linux: *<simulator install path>*/bin
Aldec Active-HDL	Windows: *<drive letter>*:*<simulator install path>*\bin
Aldec Riviera-PRO	Windows: *<drive letter>*:*<simulator install path>*\bin Linux: *<simulator install path>*/bin
Cadence Xcelium(4)	Linux: *<simulator install path>*/tools/bin/64bit

1.9.1.2. Simulation Options (Board and IP Settings Page)

The following options impact automated IP simulation model generation. Click **Tools ➤ Options ➤ Board and IP Settings ➤ IP Simulation** to specify the whether to always generate IP simulation models when generating IP for one or more simulator..

Table 9. Simulation Options (Board and IP Settings Page) Options Dialog Box

Option	Allowed Values	Description
Tool name	<None>(5) Active-HDL(6) Riviera-PRO QuestaSim Questa Intel FPGA Edition VCS/VCS MX(4) Custom(6) Xcelium(4)	Specifies the supported simulator to automatically run.
Format for output netlist	Verilog HDL VHDL	Specifies Verilog or VHDL as the format for the output netlist. The setting does not apply to RTL simulation.
Output directory	Any valid path	Specifies the directory to store all output files for simulation. Default is `simulation/<simulator>`.
Map illegal HDL characters	Disabled (Default) Enabled	When enabled, directs the EDA Netlist Writer to map illegal characters for VHDL or Verilog HDL. The setting does not apply to RTL simulation. If you select **VHDL** for **Format for output netlist**, the EDA Netlist writer maps non-alphanumeric characters, including brackets ([]), parentheses, (( )), angle brackets (<>), and braces ({}) to (_a) in VHDL Output Files. This option generates VHDL 1987 compatible names.

continued...

(4) Only supported for Linux OS.

(5) Not supported by Run Simulation

(6) Only supported for Windows OS.

Option	Allowed Values	Description
		If you select **Verilog HDL** for **Format for output netlist**, the EDA Netlist writer maps the vertical bar (|), tilde (~), and colon (:) characters in hierarchical node names to the legal Verilog HDL characters z, x, and underscore (_) in Verilog Output Files. This option also maps other illegal non-alphanumeric characters, including brackets ([]), parentheses, (( )), angle brackets (<>), and braces ({}) to underscore (_).

1.9.1.3. Simulation Flow Settings (EDA Tool Settings Page)

The simulation flow settings allow you to specify additional options for the automated simulation flow. Click **Assignments ➤ Settings ➤ EDA Tool Settings ➤ Simulation ➤ Simulation Flow Settings** to specify any of the following additional options.

Table 10. Simulation Flow Settings (EDA Tool Settings Page) Settings Dialog Box

Name	Setting	Description
Additional custom simulation elaboration options		Allows you to specify additional custom simulation elaboration options for one or more simulators. For example: `questa=-suppress 2732 -suppress 14408 -suppress 16154` `vcs=+define+IP7521SERDES_ UX_SIMSPEED`
Clean the previous simulation compile directory if exists	Off On (Default)	Allows you to clean (On) or retain (Off) the simulation directory created by the previous simulation run.
Generate third-party EDA tool command scripts	Off On (Default)	Allows you to generate only the command scripts for the third-party EDA tool without launching the simulator itself. Select Off to launch the simulator using the Run Simulation feature.
Launch third-party EDA-tool in command-line mode	Off (Default) On	Allows you to launch a third-party EDA tool in command-line mode (On) rather than opening the GUI (Off).

1.9.1.4. More EDA Netlist Writer Settings (EDA Tool Settings Page)

The **More EDA Netlist Writer Settings** dialog box allows you to specify settings that control how the Compiler generates and formats the gate-level netlist for gate-level simulation. These setting do not apply to RTL simulation.

Click **Assignments ➤ Settings ➤ EDA Tool Settings ➤ Simulation ➤ More EDA Netlist Writer Settings** to specify any of the following additional options.

Table 11. More EDA Netlist Writer Settings (EDA Tool Settings Page)

Name	Setting	Description
Architecture name in VHDL output netlist	structure	Specify the name of the architecture in the generated VHDL simulation netlist.
Bring out device-wide set/reset signals as ports	Off (Default) On	Add the `devpor`, `devclrn`, and `devoe` signals in the design as input ports in the top-level design hierarchy in the Verilog or VHDL simulation netlist for the project.
Do not write top level VHDL entity	Off (Default) On	Do not write top-level entity in VHDL Output File (`.vho`).

continued...

Name	Setting	Description
Flatten busses into individual nodes	Off (Default) On	Flattens all busses when creating the VHDL Output File (`.vho`). Turn on this option if your third-party EDA environment does not support buses.
Force Gate Level Simulation Registers to initialize to X (don't care) and propagate X	Off (Default) On	Modifies output gate level simulation netlist to force all registers to initialize to X (don't care) and propagate X.
Generate Power Estimate Scripts	Off (Default) On	Write scripts for simulation tool to generate `.vcd` file for outputs for power estimation.
Truncate long hierarchy paths	Off (Default) On	Truncate hierarchical node names to 80 characters.

1.9.2. Run RTL Simulation using Run Simulation in Batch Mode (Command-Line)

You can run RTL simulation using the Run Simulation feature in batch mode by using any of the following methods:

- By entering Tcl commands in the Quartus Prime Tcl Console.
- By entering global settings directly in the Quartus Prime Settings File (`.qsf`) (for simulation environment setup only).
- By entering commands in the Quartus Prime command-line shell:

```
quartus_sh -t <script file> \
[<script args>]
```

Note: Cadence Xcelium only supports Run Simulation in batch mode. Aldec Active-HDL only supports Run Simulation in the GUI mode.

1.9.2.1. Specifying Required Simulation Settings for Run Simulation (Batch Mode)

There are both required and optional setting for use of Run Simulation in batch mode.

The following steps describe specifying the required simulation settings for use of Run Simulation in batch mode:

1. Set the compatible EDA Simulator executable path. For example:

```
set_user_option -name EDA_TOOL_PATH_ QUESTA_INTEL /<simulator install
 path>/questa_fe_tag/24.1/92/linux64/linux_x86_64

set_user_option -name EDA_TOOL_PATH_ QUESTASIM /<simulator install
 path>/eda/mentor/questasim/2023.4/linux64/linux_x86_64

set_user_option -name EDA_TOOL_PATH_ VCS /<simulator install
 path>/eda/synopsys/vcsmx/U-2023.03-1/linux64/suse/bin

set_user_option -name EDA_TOOL_PATH_ VCS_MX /<simulator install
 path>/eda/synopsys/vcsmx/U-2023.03-1/linux64/suse/bin

set_user_option -name EDA_TOOL_PATH_ACTIVEHDL <drive letter>:\<simulator
install
 path>\eda\aldec\activehdl\13.0\windows64\bin

set_user_option -name EDA_TOOL_PATH_RIVIERAPRO /<simulator install
path>/eda/aldec/riviera/2023.04.082/linux64/bin
```

```
set_user_option -name EDA_TOOL_PATH_ XCELIUM /<simulator install
  path>/eda/cadence/xcelium/23.03.003/linux64/suse/tools.lnx86/bin
```

2. Specify your supported EDA Simulator and HDL:

```
set_global_assignment -name EDA_SIMULATION_TOOL
"<simulator> (HDL)"
```

If not set, the following is the default setting:

```
set_global_assignment -name EDA_SIMULATION_TOOL
"Questa Intel FPGA (Verilog)"
```

Table 12. Settings for EDA Simulator and HDL

Simulator	Verilog	VHDL
Questa Intel FPGA Edition	`Questa Intel FPGA (Verilog)`	`Questa Intel FPGA (VHDL)`
QuestaSim	`QuestaSim (Verilog)`	`QuestaSim (VHDL)`
VCS	`VCS`	N/A
VCS MX	`VCS MX (Verilog)`	`VCS MX (VHDL)`
Active-HDL	`Active-HDL (Verilog)`	`Active-HDL (VHDL)`
Riviera-PRO	`Riviera-PRO (Verilog)`	`Riviera-PRO (VHDL)`
Xcelium	`Xcelium (Verilog)`	`Xcelium (VHDL)`

3. Set the testbench and simulation file (if any) names, as well as the section ID (arbitrary). This is a multi-value assignment. The following shows an example with the testbench `file 1` as the top-level testbench file:

```
set_global_assignment -name EDA_TEST_BENCH_FILE <testbench file 1>
-section_id testbenchSet
set_global_assignment -name EDA_TEST_BENCH_FILE <testbench file 2>
-section_id testbenchSet
set_global_assignment -name EDA_TEST_BENCH_FILE <testbench file 3>
-section_id testbenchSet
```

4. Set the top-level module name in the top testbench file.

```
set_global_assignment -name EDA_TEST_BENCH_TOP_MODULE <testbench top module
name>
 -section_id testbenchSet
```

1.9.2.2. Optional Simulation Settings for Run Simulation (Batch Mode)

There are both required and optional setting for use of Run Simulation in batch mode.

The following examples show how to specify optional simulation settings for use of Run Simulation in batch mode:

Optional Setting To Run Simulation for Specific Time Interval

```
set_global_assignment -name EDA_TEST_BENCH_RUN_SIM_FOR “1 ns” \
-section_id testbenchSet
```

Optional Setting for Custom Wave File

```
set_global_assignment -name EDA_SIMULATION_WAVE_FILE_QUESTA_INTEL wave.do \
-section_id testbenchSet
```

Optional Setting for Elaboration Options

For Questa Intel FPGA Edition or QuestaSim:

```
set_global_assignment -name EDA_EXTRA_ELAB_OPTION
"questa=-suppress 2732 -suppress 14408 -suppress 16154" -section_id
eda_simulation
```

For VCS (Linux-only):

```
set_global_assignment -name EDA_EXTRA_ELAB_OPTION
"vcs=+define+IP7521SERDES_UX_SIMSPEED\ " -section_id eda_simulation
```

For VCS MX (Linux-only):

```
set_global_assignment -name EDA_EXTRA_ELAB_OPTION
"vcsmx=+define+IP7521SERDES_UX_SIMSPEED\ " -section_id eda_simulation
```

For Active-HDL (Windows* only):

```
set_global_assignment -name EDA_EXTRA_ELAB_OPTION
"activehdl=<third-party elab options>" -section_id eda_simulation
```

For Riviera-PRO:

```
set_global_assignment -name EDA_EXTRA_ELAB_OPTION
"rivierapro=<third-party elab option(s)>" -section_id eda_simulation
```

For Xcelium (Linux-only):

```
set_global_assignment -name EDA_EXTRA_ELAB_OPTION
"xcelium=<third-party elab option(s)>" -section_id eda_simulation
```

Simulator GUI or Batch Mode Operation Optional Setting

The default mode of this option is GUI mode. For simulator batch mode:

```
set_global_assignment -name EDA_LAUNCH_CMD_LINE_TOOL ON
-section_id eda_simulation
```

1.9.2.3. Launching Simulation with the Run Simulation Feature

After providing all the required and optional simulation settings, you can launch simulation with the Run Simulation feature in the GUI (simulator window launched) or batch (simulator window not launched) mode.

- To run RTL simulation in GUI mode (simulator window launched):

```
set_global_assignment -name EDA_LAUNCH_CMD_LINE_TOOL OFF -section_id
eda_simulation
execute_flow -simulation
```

- To run RTL simulation in batch mode (simulator window not launched):

```
set_global_assignment -name EDA_LAUNCH_CMD_LINE_TOOL ON -section_id
eda_simulation
execute_flow -simulation
```

- To generate top-level simulation and `.do` scripts only and *not* run simulation:

```
set_global_assignment -name EDA_SIMULATION_GENERATE_SCRIPT_ONLY ON -
section_id eda_simulation
execute_flow -simulation
```

1.9.2.4. Running RTL Simulation using Run Simulation

To run RTL Simulation using the Run Simulation feature, follow these steps:

1. Set up the Run Simulation feature, as Setting Up the Run Simulation Feature describes.
2. If your design includes Intel FPGA IP, you generate the simulation model and setup scripts for IP components and Platform Designer systems when generating HDL for these IP. Click the **Generate HDL** button and specify **Simulation** options for model generation. For system and IP generation details, refer to *Quartus Prime Pro Edition User Guide: Platform Designer*.
3. Click **Processing ➤ Start ➤ Start Analysis & Elaboration**. The Compilation Dashboard indicates when Analysis & Elaboration completes successfully.
4. In Quartus Prime Tcl Console, type the following command:

   ```
   execute_flow -simulation
   ```

   The Run Simulation feature compiles the simulation libraries and runs your simulator automatically, according to your settings when Setting Up the Run Simulation Feature. While the simulator is open, you are unable to make changes in the Quartus Prime software. This prevents changes to the simulation settings during simulation. The Quartus Prime software displays simulation output messages from the EDA simulator in the Messages window.
5. Analyze the simulation results in your simulator. Correct any functional errors in your design, testbench, or simulation script files. If necessary, re-simulate your design to verify correct behavior.

Related Information

Quartus Prime Pro Edition User Guide: Platform Designer

1.9.2.5. Output Directories and Files for Run Simulation

Run Simulation generates subdirectories and files inside the following output directories, according to your specifications in the Simulation Options.

```
./simulation/<simulator/arbitrary>/rtlsim/
   <project>_run_msim_rtl_<hdl>.do
      A .do file containing the simulator settings
   run_sim_command.sh (or .bat for Windows)
      A .sh/.bat file to rerun the simulation only (standalone, i.e., without
      rerunning Quartus Prime compilation and elaboration)
   <simulator/arbitrary>_transcript.log
      A simulator transcript file
```

```
./simulation/<simulator or arbitrary>/rtlsim/<project>_iputf_input
   ./aldec
      rivierapro_setup.tcl
   ./common
      modelsim_files.tcl
      riviera_files.tcl
      vcs_files.tcl
      vcsmx_files.tcl
      xcelium_files.tcl
   ./mentor
      msim_setup.tcl
   ./synopsys
      ./vcs
         vcs_setup.sh
      ./vcsmx
         synopsys_sim.setup
         vcsmx_setup.sh
   ./xcelium
      cds.lib
      hdl.var
      xcelium_setup.sh
      ./cds_libs
         Project library files
```

1.10. Intel FPGA Simulation Basics Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Updated simulator versions supported in *Supported Simulators* topic. • Revised *Supported Simulation Flows* topic to include the Run Simulation feature. • Added new *Automating Simulation with the Run Simulation Feature* section. • Applied phase I rebranding throughout.
2023.12.07	23.4	• Added new *Post-Fit Simulation by Intel FPGA Family* topic. • Updated simulator versions supported in *Supported Simulators* topic.
2022.12.21	22.4	• Replaced all content in chapter with newly developed content more suitable for basic understanding of FPGA design simulation. • Updated chapter to reflect end of support for ModelSim and relocation of Questa Intel FPGA Edition information to new *Questa Intel FPGA Edition Simulation User Guide*.
2022.04.13	22.1	• Updated simulator versions supported in *Simulator Support* topic. • Added note about longer compilation times to *Compiling Simulation Module Libraries* topic.

continued...

Document Version	Quartus Prime Version	Changes
2021.10.05	21.3	• Updated simulator versions supported in *Simulator Support* topic. • Revised name of Questa Intel FPGA Edition and QuestaSim for latest guidelines throughout. • Updated default output directory name to questa in *Using the EDA Netlist Writer* topic.
2021.10.04	21.3	• Revised *Generating IP Simulation Files* steps to include generation of all IP in the design at once.
2021.06.21	21.2	• Changed chapter title to *FPGA Simulation Basics* from *Simulating Intel FPGA Designs*. • Added support for Questa Intel FPGA Edition simulator throughout. • Removed support for ModelSim - Intel FPGA Edition simulator throughout. • Updated simulator versions supported in *Simulator Support* topic. • Added precompiled libraries footnote to *Supported Hardware Description Languages* and *Compiling Simulation Model Libraries* topics. • Revised *Running a Simulation (Custom Flow)* topic to add missing EDA Netlist Writer step and related links. • Replaced "Mentor Graphics" with "Siemens EDA" to reflect current company name. • Updated *Supported Hardware Description Languages* for note on schematic conversion. • Revised *Scripting IP Simulation* to correct typo in step 1. • Added links to *Incorporating Simulator Setup Scripts from the Generated Template* topic.
2021.03.29	21.1	• Added note about X propagation limit of the Quartus Prime-provided clock divider simulation model to the *Compiling Simulation Model Libraries* topic.
2020.10.10	20.1	• Revised *Generating IP Simulation Files* topic for new simulation file output options. • Updated supported simulator versions and removed support for Cadence Incisive Enterprise* in *Simulator Support* topic.

2. Siemens EDA QuestaSim Simulator Support

This chapter provides guidelines for simulation of Quartus Prime designs with the supported Siemens EDA QuestaSim simulators.

Note: Intel also provides the Questa Intel FPGA Edition simulator, a version of the Questa Advanced simulator targeted for Intel FPGA devices. The Questa Intel FPGA Edition simulator supports the Intel FPGA gate-level simulation libraries, and includes behavioral simulation, HDL test benches, and Tcl scripting support. Refer to the *Questa Intel FPGA Edition Simulation User Guide* for complete information.

Related Information

Questa Intel FPGA Edition Simulation User Guide

2.1. Quick Start Example (QuestaSim with Verilog)

You can adapt the following RTL simulation example to get started quickly with QuestaSim:

1. To specify your EDA simulator and executable path, type the following Tcl package command in the Quartus Prime tcl shell window:

   `set_user_option -name EDA_TOOL_PATH_QUESTASIM <questasim executable path>`

   `set_global_assignment -name EDA_SIMULATION_TOOL "QuestaSim (Verilog)"`

2. Compile simulation model libraries using one of the following methods:
   - To automatically compile all required simulation model libraries for your design in your supported simulator, click **Tools ➤ Launch Simulation Library Compiler**. Specify options for your simulation tool, language, target device family, and output location, and then click **OK**.
   - Type the following commands to create and map Intel FPGA simulation libraries manually, and then compile the models manually:

     ```
     vlib <lib1>_ver
     vmap <lib1>_ver <lib1>_ver
     vlog -work <lib1> <lib1>
     ```

   Use the compiled simulation model libraries during simulation of your design. Refer to your EDA simulator's documentation for information about running simulation.

3. Compile your design and testbench files:

   ```
   vlog -work work <design or testbench name>.v
   ```

4. Load the design:

```
vsim -L work -L <lib1>_ver -L <lib2>_ver work.<testbench name>
```

2.2. QuestaSim Simulator Guidelines

The following guidelines apply to simulation of Quartus Prime designs with QuestaSim.

2.2.1. Passing Parameter Information from Verilog HDL to VHDL

You must use in-line parameters to pass values from Verilog HDL to VHDL.

By default, the **x_on_violation_option** logic option is enabled for all design registers, resulting in an output of "X" at timing violation. To disable "X" propagation at timing violations on a specific register, disable the **x_on_violation_option** logic option for the specific register, as shown in the following example from the Quartus Prime Settings File (`.qsf`).

```
set_instance_assignment -name X_ON_VIOLATION_OPTION OFF -to \
<register_name>
```

Example 1. In-line Parameter Passing Example

```
lpm_add_sub#(.lpm_width(12), .lpm_direction("Add"),
.lpm_type("LPM_ADD_SUB"),
.lpm_hint("ONE_INPUT_IS_CONSTANT=NO,CIN_USED=NO" ))

lpm_add_sub_component (
        .dataa (dataa),
        .datab (datab),
        .result (sub_wire0)
);
```

Note: The sequence of the parameters depends on the sequence of the GENERIC in the VHDL component declaration.

2.2.2. Viewing Simulation Messages

QuestaSim simulator error and warning messages are tagged with a `vsim` or `vcom` code. To determine the cause and resolution for a `vsim` or `vcom` error or warning, use the `verror` command.

For example, QuestaSim may return the following error:

```
# ** Error: C:/altera_trn/DUALPORT_TRY/simulation/questa/DUALPORT_TRY.vho(31):
 (vcom-1136) Unknown identifier "stratixiv"
```

In this case, type the following command:

`verror 1136`
The following description appears:

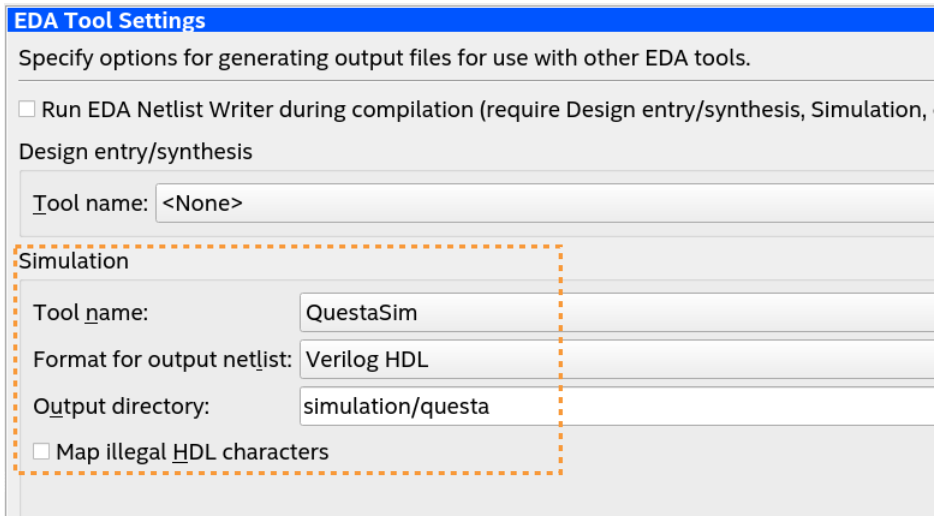
```
# vcom Message # 1136:
# The specified name was referenced but was not found. This indicates
# that either the name specified does not exist or is not visible at
# this point in the code.
```

2.2.3. Generating Signal Activity Data for Power Analysis

To generate and use simulation signal activity data for power analysis:

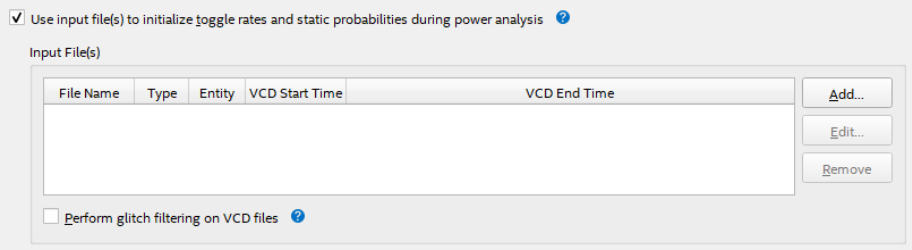
1. To run full compilation on your design, click **Processing ➤ Start Compilation**.
2. To specify settings for simulation output, click **Assignments ➤ Settings ➤ EDA Tool Settings ➤ Simulation**. Select your simulator in **Tool name** and the **Format for output netlist** and **Output directory**.

Figure 11. EDA Tool Settings for Simulation



3. Turn on **Map illegal HDL characters**. This setting directs the EDA Netlist Writer to map illegal characters for VHDL or Verilog HDL, and results in more accurate data for power analysis.
4. Click the **Power Analyzer Settings** page.
5. Under **Input file**, turn on **Use input files to initialize toggle rates and static probabilities during power analysis**.

Figure 12. Specifying Power Analysis Input Files



6. To specify a `.vcd` for power analysis, click **Add** and specify the **File name**, **Entity**, and **Simulation period** for the `.vcd`, and click **OK**.
7. To enable glitch filtering during power analysis with the `.vcd` you generate, turn on **Perform glitch filtering on VCD files**.
8. To run the power analysis, click **Start** on the **Power Analysis** step in the Compilation Dashboard. View the toggle rates in the power analysis results.

2.2.4. Viewing Simulation Waveforms

QuestaSim automatically generates a Wave Log Format File (`.wlf`) following simulation. You can use the `.wlf` to generate a waveform view.

To view a waveform from a `.wlf` through QuestaSim, perform the following steps:

1. Type `vsim` at the command line. The **QuestaSim** dialog box appears.
2. Click **File ➤ Datasets**. The **Datasets Browser** dialog box appears.
3. Click **Open** and select your `.wlf`.
4. Click **Done**.
5. In the Object browser, select the signals that you want to observe.
6. Click **Add ➤ Wave**, and then click **Selected Signals**.
   You must first convert the `.vcd` to a `.wlf` before you can view a waveform in QuestaSim.
7. To convert the `.vcd` to a `.wlf`, type the following at the command-line:

   ```
   vcd2wlf <example>.vcd <example>.wlf
   ```

8. After conversion, view the `.wlf` waveform in QuestaSim.

2.3. Using the Qrun Flow

The Quartus Prime Pro Edition software now supports a new Qrun flow for IP generation. The Qrun flow optionally creates simulation files, including the functional simulation model, and any testbench (or example design).

The Qrun flow, for use with only the QuestaSim and Questa Intel FPGA Edition simulators, is an enhancement over the traditional flow that can automatically combine the compile, optimize, and simulate functions into a single step.

This section describes how to specify the Qrun settings, generate the system or component simulation model and simulator setup scripts, and generate the testbench and example design.

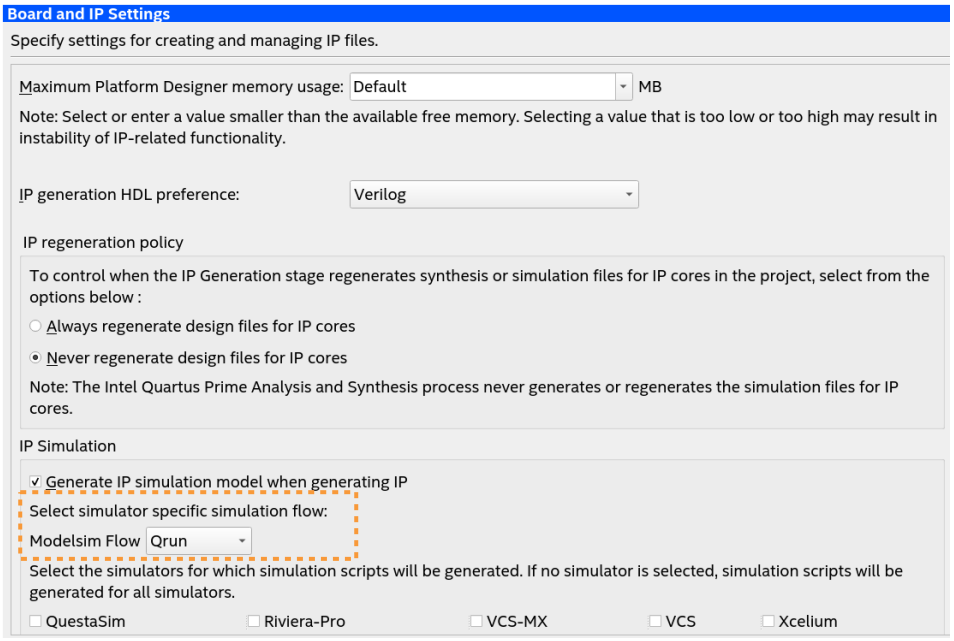
2.3.1. Specifying Simulation File Generation Settings

Before generating simulation files using the Qrun flow, you specify your supported simulator and other options for simulation file generation. These setting impact the generation of simulation files when generating HDL for IP in your project.

To specify simulation file generation settings, follow these steps:

1. In the Quartus Prime Pro Edition software, click **Assignments ➤ Settings ➤ Board and IP Settings**. The **Board and IP Settings** dialog box appears.
2. Under **IP Simulation**, turn on **Generate IP simulation model when generating IP**. Turning on this option enables the remaining settings.
3. For **Select simulator specific simulation flow**, make sure **Qrun** is selected to enable the Qrun flow. The alternative setting runs the **Traditional** flow.

Figure 13. Board and IP Settings Page of Settings Dialog Box



4. To specify one or more specific simulators for which to generate simulation files, enable the checkbox for those simulators. To enable generation for all supported simulators, leave all checkboxes disabled (default setting).

To generate the simulation model and simulator setup scripts for your Platform Designer system or IP component in batch mode, use this command:

```
ip-make-simscript [args] --modelsim_flow=QRUN
```

Type `ip-make-simscript -help` for all available arguments (`[args]`).

2.3.2. Generating the Simulation Model and Setup Scripts

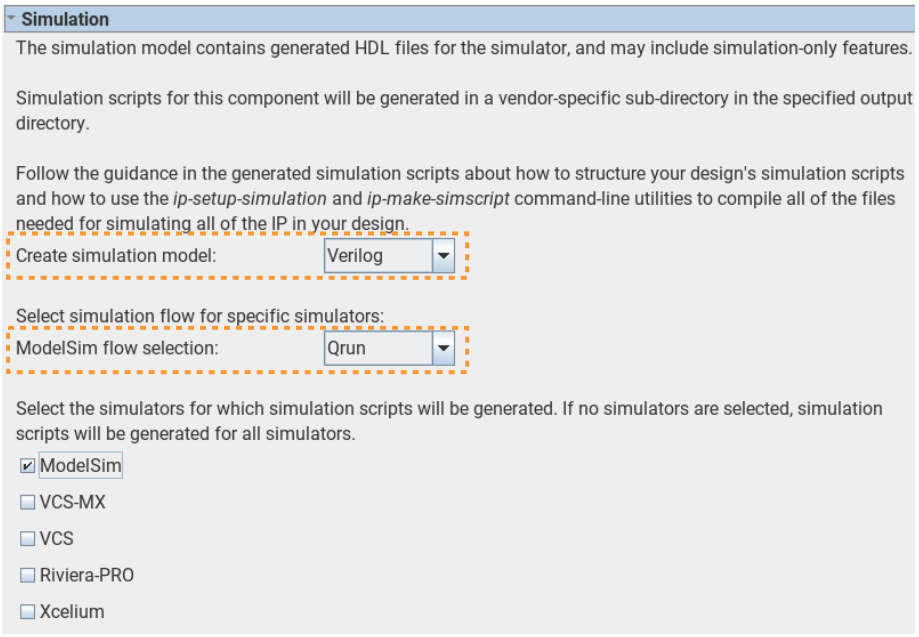
You generate the simulation model and setup scripts for IP components and Platform Designer systems when generating HDL for these IP in your project.

Platform Designer generates the simulation model and setup scripts according to your specifications in Specifying Simulation File Generation Settings.

To generate the simulation model and simulator setup scripts for your Platform Designer system or IP component, follow these steps:

1. In the Quartus Prime Pro Edition software, click **Tools ➤ Platform Designer** and open or create an IP variant or Platform Designer system.
2. After specifying any IP component or system parameters in the parameter editor, click the **Generate HDL** button. The **Generation** dialog box appears.
3. Under **Simulation**, select either **Verilog** or **VHDL** for **Create Simulation Model**. Selecting one of these options makes the **Modelsim flow selection** setting editable.
4. For **Modelsim flow selection**, make sure **Qrun** is selected to enable the Qrun flow. The alternative setting runs the **Traditional** flow.

Figure 14. Generation Dialog Box Settings



5. To specify one or more specific simulators for which to generate simulation files, enable the checkbox for those simulators. To enable generation for all supported simulators, leave all checkboxes disabled (default setting).
6. Click **Generate**. Platform Designer generates the simulation models and setup scripts for your system or IP component in the *<project>/<IP name>*/sim/<vendor> directory.

To generate the simulation model and simulator setup scripts for your Platform Designer system or IP component in batch mode, use this command:

```
qsys-generate <file> [args] --modelsim_flow=QRUN
```

2.3.3. Generating the Testbench System

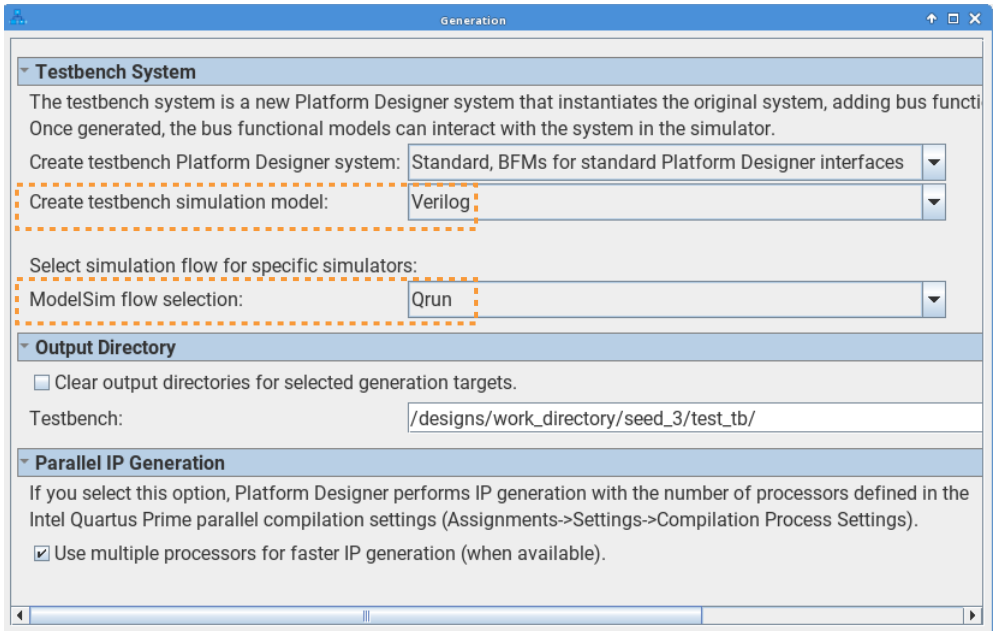
You can optionally generate a testbench system that instantiates the original system, adding bus functional models to drive the top-level interfaces. Once generated, the bus functional models can interact with the system or IP in the simulator.

Platform Designer generates the simulation model and setup scripts according to your specifications in Specifying Simulation File Generation Settings.

To generate the testbench system for a Platform Designer system or IP component, follow these steps:

1. In the Quartus Prime Pro Edition software, click **Tools ➤ Platform Designer** and open or create an IP variant or Platform Designer system.
2. After specifying any IP component or system parameters in the parameter editor, click the **Generate ➤ Generate Testbench System** button. The **Generation** dialog box appears.
3. Under **Testbench System**, select either **Verilog** or **VHDL** for **Create testbench simulation model**. Selecting one of these options makes the **Modelsim flow selection** setting editable.
4. For **Modelsim flow selection**, make sure **Qrun** is selected to enable the Qrun flow. The alternative setting runs the **Traditional** flow.

Figure 15. Generation Dialog Box Settings



5. Click **Generate**. Platform Designer generates the simulation models and setup scripts for your system or IP component under the specified **Output Directory**.

2.3.4. Generating Example Design Simulation Files

When you run **Generate ➤ Generate Example Design**, Platform Designer automatically generates the simulator setup script `msim_setup.tcl` containing `qrun` commands.

2.3.5. Recommendations for Using Qrun

- Mixing of traditional and Qrun generated simulation scripts is not supported.
- Although mixing of vlog and vcom and qrun commands is allowed, you can write testbench scripts using vlog and vcom and generated scripts with qrun or vice versa.

2.4. QuestaSim Simulation Setup Script Example

The Quartus Prime software can generate a `msim_setup.tcl` simulation setup script for IP cores in your design. The script compiles the required device library models, compiles the design files, and elaborates the design with or without simulator optimization. To run the script, type source `msim_setup.tcl` in the simulator Transcript window.

Alternatively, if you are using the simulator at the command line, you can type the following command:

```
vsim -c -do msim_setup.tcl
```

In this example the `top-level-simulate.do` custom top-level simulation script sets the hierarchy variable `TOP_LEVEL_NAME` to `top_testbench` for the design, and sets the variable `QSYS_SIMDIR` to the location of the generated simulation files.

```
# Set hierarchy variables used in the IP-generated files
set TOP_LEVEL_NAME "top_testbench"
set QSYS_SIMDIR "./ip_top_sim"
# Source generated simulation script which defines aliases used below
source $QSYS_SIMDIR/mentor/msim_setup.tcl
# dev_com alias compiles simulation libraries for device library files
dev_com
# com alias compiles IP simulation or Platform Designer model files and/or
Platform Designer model files in the correct order
com
# Compile top level testbench that instantiates your IP
vlog -sv ./top_testbench.sv
# elab alias elaborates the top-level design and testbench
elab
# Run the full simulation
run - all
```

In this example, the top-level simulation files are stored in the same directory as the original IP core, so this variable is set to the IP-generated directory structure. The `QSYS_SIMDIR` variable provides the relative hierarchy path for the generated IP simulation files. The script calls the generated `msim_setup.tcl` script and uses the alias commands from the script to compile and elaborate the IP files required for simulation along with the top-level simulation testbench. You can specify additional simulator elaboration command options when you run the `elab` command, for example, `elab +nowarnTFMPC`. The last command run in the example starts the simulation.

2.5. Sourcing QuestaSim Simulator Setup Scripts

Follow these steps to incorporate the generated or QuestaSim IP simulation scripts into a top-level project simulation script.

1. The generated simulation script contains the following template lines. Cut and paste these lines into a new file. For example, `sim_top.do`.

```
# # Start of template
# # If the copied and modified template file is "mentor.do", run it
# # as: vsim -c -do mentor.do
# #
# # Source the generated sim script
# source msim_setup.tcl
# # Compile eda/sim_lib contents first
# dev_com
```

```
# # Override the top-level name (so that elab is useful)
# set TOP_LEVEL_NAME top
# # Compile the standalone IP.
# com
# # Compile the top-level
# vlog -sv ../../top.sv
# # Elaborate the design.
# elab
# # Run the simulation
# run -a
# # Report success to the shell
# exit -code 0
# # End of template
```

2. Delete the first two characters of each line (comment and space):

```
# Start of template
# If the copied and modified template file is "mentor.do", run it
# as: vsim -c -do mentor.do
#
# Source the generated sim script
source msim_setup.tcl
# Compile eda/sim_lib contents first
dev_com
# Override the top-level name (so that elab is useful)
set TOP_LEVEL_NAME top
# Compile the standalone IP.
com
# Compile the top-level
vlog -sv ../../top.sv
# Elaborate the design.
elab
# Run the simulation
run -a
# Report success to the shell
exit -code 0
# End of template
```

3. Modify the TOP_LEVEL_NAME and compilation step appropriately, depending on the location of the simulation's top-level file. For example:

```
set TOP_LEVEL_NAME sim_top vlog -sv ../../sim_top.sv
```

4. If necessary, add the QSYS_SIMDIR variable to point to the location of the generated IP simulation files. Specify any other changes required to match your design simulation requirements. The scripts offer variables to set compilation or simulation options. Refer to the generated script for details.
5. Run the resulting top-level script from the generated simulation directory:

```
vsim –c –do <path to sim_top>.tcl
```

2.6. Unsupported Features

The Quartus Prime software does not support the following simulation features:

- Some versions of QuestaSim support SystemVerilog, PSL assertions, SystemC, and more. For more information about specific feature support, refer to Siemens EDA software documentation.

2.7. Siemens EDA QuestaSim Simulator Support Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Added new *Using the Qrun Flow in Platform Designer* section.
2023.10.02	23.3	• Updated chapter to reflect end of support for ModelSim. • Referenced new Questa Intel FPGA Edition information to new *Questa Intel FPGA Edition Simulation User Guide*. • Removed obsolete *Generating Standard Delay Output for Power Analysis* topic. Generation of SDO files is no longer supported in the Quartus Prime Pro Edition software.
2022.04.13	22.1	• Revised name of Questa Intel FPGA Edition and QuestaSim for latest guidelines throughout.
2021.10.04	21.3	• Added support for Questa Intel FPGA Edition simulator. • Removed support for ModelSim - Intel FPGA Edition simulator. • Updated directory names in *Using Questa Intel FPGA Edition Precompiled Libraries* topic. • Removed note about Maintain Hierarchy limit in *Viewing Simulation Messages* topic. • Replaced "Mentor Graphics" with "Siemens EDA" to reflect current company name.
2021.03.29	21.1	Updated *Generating Signal Activity Data for Power Analysis* topic for latest behavior.
2019.06.19	19.1.0	• Added footnote about ModelSim Remote Desktop limits to "Unsupported Features" topic.
2019.04.01	19.1.0	• Described new support for generation of SDO for use in power analysis.
2017.11.06	17.1.0	• Changed title to ModelSim - Intel FPGA Edition, ModelSim*, and QuestaSim Support* • Removed Simulating Transport Delays and Disabling Timing Violations on Registers topics. Quartus Prime Pro Edition does not support timing simulation. • Added Simulation Library Compiler details and another step to Quick Start Example

3. Synopsys VCS and VCS MX Support

You can include your supported EDA simulator in the Quartus Prime design flow. This document provides guidelines for simulation of Quartus Prime designs with the Synopsys VCS or VCS MX software.

3.1. Quick Start Example (VCS with Verilog)

You can adapt the following RTL simulation example to get started quickly with VCS:

1. To specify your EDA simulator and executable path, type the following Tcl package command in the Quartus Prime tcl shell window:

   `set_user_option -name EDA_TOOL_PATH_VCS <`*VCS executable path*`>`

   `set_global_assignment -name EDA_SIMULATION_TOOL "VCS"`

2. Compile simulation model libraries using the following method:
   - To automatically compile all required simulation model libraries for your design in your supported simulator, click **Tools ➤ Launch Simulation Library Compiler**. Specify options for your simulation tool, language, target device family, and output location, and then click **OK**.

   Use the compiled simulation model libraries during simulation of your design. Refer to your EDA simulator's documentation for information about running simulation.
3. Modify the `simlib_comp.vcs` file to specify your design and testbench files.
4. Type the following to run the VCS simulator:

```
vcs -R -file simlib_comp.vcs
```

3.2. VCS and VCS MX Guidelines

The following guidelines apply to simulation of Intel FPGA designs in the VCS or VCS MX software:

- Do not specify the -v option for `altera_lnsim.sv` because it defines a systemverilog package.
- Add `-verilog` and `+verilog2001ext+.v` options to make sure all **.v** files are compiled as verilog 2001 files, and all other files are compiled as systemverilog files.
- Add the `-lca` option for Stratix V and later families because they include IEEE-encrypted simulation files for VCS and VCS MX.
- Add `-timescale=1ps/1ps` to ensure picosecond resolution.

3.3. VCS Simulation Setup Script Example

The Quartus Prime software can generate a simulation setup script for IP cores in your design. The scripts contain shell commands that compile the required simulation models in the correct order, elaborate the top-level design, and run the simulation for 100 time units by default. You can run these scripts from a Linux command shell.

The scripts for VCS and VCS MX are `vcs_setup.sh` (for Verilog HDL or SystemVerilog) and `vcsmx_setup.sh` (combined Verilog HDL and SystemVerilog with VHDL). Read the generated `.sh` script to see the variables that are available for override when sourcing the script or redefining directly if you edit the script. To set up the simulation for a design, use the command-line to pass variable values to the shell script.

Example 2. Using Command-line to Pass Simulation Variables

```
sh vcsmx_setup.sh\
USER_DEFINED_ELAB_OPTIONS=+rad\
USER_DEFINED_SIM_OPTIONS=+vcs+lic+wait
```

Example 3. Example Top-Level Simulation Shell Script for VCS-MX

```
# Run generated script to compile libraries and IP simulation files
# Skip elaboration and simulation of the IP variation
sh ./ip_top_sim/synopsys/vcsmx/vcsmx_setup.sh SKIP_ELAB=1 SKIP_SIM=1
QSYS_SIMDIR="./ip_top_sim"
#Compile top-level testbench that instantiates IP
vlogan -sverilog ./top_testbench.sv
#Elaborate and simulate the top-level design
vcs –lca –t ps <elaboration control options> top_testbench
simv <simulation control options>
```

Example 4. Example Top-Level Simulation Shell Script for VCS

```
# Run script to compile libraries and IP simulation files
sh ./ip_top_sim/synopsys/vcs/vcs_setup.sh TOP_LEVEL_NAME=”top_testbench”\
# Pass VCS elaboration options to compile files and elaborate top-level
 passed to the script as the TOP_LEVEL_NAME
USER_DEFINED_ELAB_OPTIONS="top_testbench.sv"\
# Pass in simulation options and run the simulation for specified amount of time.
USER_DEFINED_SIM_OPTIONS=”<simulation control options>
```

3.4. Sourcing Synopsys VCS MX Simulator Setup Scripts

Follow these steps to incorporate the generated Synopsys VCS MX simulation scripts for use in top-level project simulation scripts.

1. The generated simulation script contains these template lines. Cut and paste the lines preceding the “helper file” into a new executable file. For example, `vcsmx.sh`.

```
# # Start of template
# # If the copied and modified template file is "vcsmx_sim.sh", run
# # it as: ./vcsmx_sim.sh
# #
# # Do the file copy, dev_com and com steps
# source vcsmx_setup.sh
# SKIP_ELAB=1

# SKIP_SIM=1
#
# # Compile the top level module
```

```
# vlogan +v2k
     +systemverilogext+.sv "$QSYS_SIMDIR/../top.sv"

# # Do the elaboration and sim steps
# # Override the top-level name
# # Override the sim options, so the simulation runs
# # forever (until $finish()).
# source vcsmx_setup.sh
# SKIP_FILE_COPY=1
# SKIP_DEV_COM=1
# SKIP_COM=1
# TOP_LEVEL_NAME="'-top top'"
# USER_DEFINED_SIM_OPTIONS=""
# # End of template
```

2. Delete the first two characters of each line (comment and space), as shown below:

```
# Start of template
# If the copied and modified template file is "vcsmx_sim.sh", run
# it as: ./vcsmx_sim.sh
#
# Do the file copy, dev_com and com steps
source vcsmx_setup.sh
SKIP_ELAB=1
SKIP_SIM=1

# Compile the top level module
vlogan +v2k +systemverilogext+.sv "$QSYS_SIMDIR/../top.sv"

# Do the elaboration and sim steps
# Override the top-level name
# Override the sim options, so the simulation runs
# forever (until $finish()).
source vcsmx_setup.sh
SKIP_FILE_COPY=1
SKIP_DEV_COM=1
SKIP_COM=1
TOP_LEVEL_NAME="'-top top'"
USER_DEFINED_SIM_OPTIONS=""
# End of template
```

3. Modify the TOP_LEVEL_NAME and compilation step appropriately, depending on the simulation's top-level file. For example:

```
TOP_LEVEL_NAME="'-top sim_top'"
```

4. Make the appropriate changes to the compilation of your top-level file, for example:

```
vlogan +v2k +systemverilogext+.sv "$QSYS_SIMDIR/../sim_top.sv"
```

5. If necessary, add the QSYS_SIMDIR variable to point to the location of the generated IP simulation files. Specify any other changes required to match your design simulation requirements. The scripts offer variables to set compilation or simulation options. Refer to the generated script for details.
6. Run the resulting top-level script from the generated simulation directory by specifying the path to `vcsmx_sim.sh`.

3.5. Sourcing Synopsys VCS Simulator Setup Scripts

Follow these steps to incorporate the generated Synopsys VCS simulation scripts into a top-level project simulation script.

1. The generated simulation script contains these template lines. Cut and paste the lines preceding the "helper file" into a new executable file. For example, `synopsys_vcs.f`.

```
# # Start of template
# # If the copied and modified template file is "vcs_sim.sh", run it
# # as: ./vcs_sim.sh
# #
# # Override the top-level name
# # specify a command file containing elaboration options
# # (system verilog extension, and compile the top-level).
# # Override the sim options, so the simulation
# # runs forever (until $finish()).
# source vcs_setup.sh
# TOP_LEVEL_NAME=top
# USER_DEFINED_ELAB_OPTIONS="'-f ../../../synopsys_vcs.f'"
# USER_DEFINED_SIM_OPTIONS=""
#
# # helper file: synopsys_vcs.f
# +systemverilogext+.sv
# ../../../top.sv
# # End of template
```

2. Delete the first two characters of each line (comment and space) for the `vcs.sh` file, as shown below:

```
# Start of template
# If the copied and modified template file is "vcs_sim.sh", run it
# as: ./vcs_sim.sh
#
# Override the top-level name
# specify a command file containing elaboration options
# (system verilog extension, and compile the top-level).
# Override the sim options, so the simulation
# runs forever (until $finish()).
source vcs_setup.sh
TOP_LEVEL_NAME=top
USER_DEFINED_ELAB_OPTIONS="'-f ../../../synopsys_vcs.f'"
USER_DEFINED_SIM_OPTIONS=""
```

3. Delete the first two characters of each line (comment and space) for the `synopsys_vcs.f` file, as shown below:

```
# helper file: synopsys_vcs.f
 +systemverilogext+.sv
 ../../../top.sv
# End of template
```

4. Modify the `TOP_LEVEL_NAME` and compilation step appropriately, depending on the simulation's top-level file. For example:

```
TOP_LEVEL_NAME=sim_top
```

5. If necessary, add the `QSYS_SIMDIR` variable to point to the location of the generated IP simulation files. Specify any other changes required to match your design simulation requirements. The scripts offer variables to set compilation or simulation options. Refer to the generated script for details.
6. Run the resulting top-level script from the generated simulation directory by specifying the path to `vcs_sim.sh`.

3.6. Synopsys VCS and VCS MX Support Revision History

Document Version	Quartus Prime Version	Changes
2022.04.13	22.1	• Revised name of Questa Intel FPGA Edition and QuestaSim for latest guidelines throughout.
2017.11.06	17.1	• Removed Simulating Transport Delays and Disabling Timing Violations on Registers topics. Quartus Prime Pro Edition does not support timing simulation. • Added Simulation Library Compiler details and another step to Quick Start Example

4. Aldec Active-HDL and Riviera-PRO Support

You can include your supported EDA simulator in the Quartus Prime design flow. This chapter provides specific guidelines for simulation of Quartus Prime designs with the Aldec Active-HDL or Riviera-PRO software.

4.1. Quick Start Example (Active-HDL VHDL)

You can adapt the following RTL simulation example to get started quickly with Active-HDL:

1. To specify your EDA simulator and executable path, type the following Tcl package command in the Quartus Prime Tcl shell window:

   `set_user_option -name EDA_TOOL_PATH_ACTIVEHDL <Active HDL executable path>`

   `set_global_assignment -name EDA_SIMULATION_TOOL "Active-HDL (VHDL)"`

2. Compile simulation model libraries using one of the following methods:
   - To automatically compile all required simulation model libraries for your design in your supported simulator, click **Tools ➤ Launch Simulation Library Compiler**. Specify options for your simulation tool, language, target device family, and output location, and then click **OK**.
   - Compile Intel FPGA simulation models manually:

     ```
     vlib <library1> <altera_library1>
     vcom -strict93 -dbg -work <library1> <lib1_component/pack.vhd> \
        <lib1.vhd>
     ```

   Use the compiled simulation model libraries during simulation of your design. Refer to your EDA simulator's documentation for information about running simulation.
3. Open the Active-HDL simulator.
4. Create and open the workspace:

   ```
   createdesign <workspace name> <workspace path>
   opendesign -a <workspace name>.adf
   ```

5. Create the work library and compile the netlist and testbench files:

   ```
   vlib work
   vcom  -strict93  -dbg -work work <output netlist> <testbench file>
   ```

6. Load the design:

   ```
   vsim +access+r -t 1ps +transport_int_delays +transport_path_delays \
   -L work -L <lib1> -L <lib2> work.<testbench module name>
   ```

7. Run the simulation in the Active-HDL simulator.

4.2. Aldec Active-HDL and Riviera-PRO Guidelines

The following guidelines apply to simulating Intel FPGA designs in the Active-HDL or Riviera-PRO software.

Compiling SystemVerilog Files

If your design includes multiple SystemVerilog files, you must compile the SystemVerilog files together with a single `alog` command.

If you have Verilog files and SystemVerilog files in your design, you must first compile the Verilog files, and then compile only the SystemVerilog files in the single `alog` command.

4.3. Using Simulation Setup Scripts

The Quartus Prime software can generate the `rivierapro_setup.tcl` simulation setup script for Intel FPGA IP cores in your design. The use and content of the script file is similar to the `msim_setup.tcl` file that the Quartus Prime software generates for use with the QuestaSim simulator.

4.4. Sourcing Aldec ActiveHDL* or Riviera Pro* Simulator Setup Scripts

Follow these steps to incorporate the generated ActiveHDL* or Riviera Pro* simulation scripts into a top-level project simulation script.

1. The generated simulation script contains the following template lines. Cut and paste these lines into a new file. For example, `sim_top.tcl`.

```
# # TOP-LEVEL TEMPLATE - BEGIN
# #
# # QSYS_SIMDIR is used in the Quartus-generated IP simulation script to
# # construct paths to the files required to simulate the IP in your Quartus
# # project. By default, the IP script assumes that you are launching the
# # simulator from the IP script location. If launching from another
# # location, set QSYS_SIMDIR to the output directory you specified when you
# # generated the IP script, relative to the directory from which you launch
# # the simulator.
# #
# set QSYS_SIMDIR <script generation output directory>
# #
# # Source the generated IP simulation script.
# source $QSYS_SIMDIR/aldec/rivierapro_setup.tcl
# #
# # Set any compilation options you require (this is unusual).
# set USER_DEFINED_COMPILE_OPTIONS <compilation options>
# set USER_DEFINED_VHDL_COMPILE_OPTIONS <compilation options for VHDL>
# set USER_DEFINED_VERILOG_COMPILE_OPTIONS <compilation options for Verilog>
# #
# # Call command to compile the Quartus EDA simulation library.
# dev_com
# #
# # Call command to compile the Quartus-generated IP simulation files.
# com
# #
# # Add commands to compile all design files and testbench files, including
# # the top level. (These are all the files required for simulation other
```

```
# # than the files compiled by the Quartus-generated IP simulation script)
# #
# vlog -sv2k5 <your compilation options> <design and testbench files>
# #
# # Set the top-level simulation or testbench module/entity name, which is
# # used by the elab command to elaborate the top level.
# #
# set TOP_LEVEL_NAME <simulation top>
# #
# # Set any elaboration options you require.
# set USER_DEFINED_ELAB_OPTIONS <elaboration options>
# #
# # Call command to elaborate your design and testbench.
# elab
# #
# # Run the simulation.
# run
# #
# # Report success to the shell.
# exit -code 0
# #
# # TOP-LEVEL TEMPLATE - END
```

2. Delete the first two characters of each line (comment and space):

```
# TOP-LEVEL TEMPLATE - BEGIN
#
# QSYS_SIMDIR is used in the Quartus-generated IP simulation script to
# construct paths to the files required to simulate the IP in your Quartus
# project. By default, the IP script assumes that you are launching the
# simulator from the IP script location. If launching from another
# location, set QSYS_SIMDIR to the output directory you specified when you
# generated the IP script, relative to the directory from which you launch
# the simulator.
#
set QSYS_SIMDIR <script generation output directory>
#
# Source the generated IP simulation script.
source $QSYS_SIMDIR/aldec/rivierapro_setup.tcl
#
# Set any compilation options you require (this is unusual).
set USER_DEFINED_COMPILE_OPTIONS <compilation options>
set USER_DEFINED_VHDL_COMPILE_OPTIONS <compilation options for VHDL>
set USER_DEFINED_VERILOG_COMPILE_OPTIONS <compilation options for Verilog>
#
# Call command to compile the Quartus EDA simulation library.

 #
 # Run the simulation.
run -all
 #
 # Report success to the shell.
 exit -code 0
 #
 # TOP-LEVEL TEMPLATE - END
```

5. To view all available options, invoke the Active-HDL or Riviera-PRO license and launch the simulator by typing `vsim` in command-line mode. After the simulator launches, type `help` in the simulator Console panel. To view options related to a specific command, for example the `vsim` simulation command, type `help vsim` in the simulator Console panel.
6. Run the new top-level script from the generated simulation directory in command-line mode. To run the simulation in GUI mode, type the following:

```
vsim -gui -l log.txt +access +r -lib dsn tb -do sim_top.tcl
```

To run the simulation in command-line mode, type the following:

```
vsim –c –do sim_top.tcl
```

4.5. Aldec Active-HDL and Riviera-PRO * Support Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Updated script content in *Sourcing Aldec ActiveHDL or Riviera Pro* Simulator Setup Scripts* topic.
2023.10.02	23.3	• Updated chapter to reflect end of support for generation of ModelSim files in favor of QuestaSim.
2022.04.13	22.1	• Revised name of Questa Intel FPGA Edition and QuestaSim for latest guidelines throughout.
2017.11.06	17.1	• Removed Simulating Transport Delays and Disabling Timing Violations on Registers topics. Quartus Prime Pro Edition does not support timing simulation. • Added Simulation Library Compiler details and another step to Quick Start Example

5. Cadence Xcelium Parallel Simulator Support

You can include your supported EDA simulator in the Quartus Prime Pro Edition design flow. This chapter provides specific guidelines for simulation of Quartus Prime Pro Edition designs with the Cadence Xcelium Parallel Simulator software.

5.1. Using the Command-Line Interface

The Quartus Prime Pro Edition software provides command-line support for the Xcelium Parallel Simulator.

The following Xcelium simulation executables are available:

Table 13. Xcelium Simulation Executables

Program	Function
`xrun`	`xrun` compiles and runs your design based on the compilation and run options you define.
`xmvlog`	`xmvlog` compiles your Verilog HDL code and performs syntax and static semantics checks.
`xmvhdl`	`xmvhdl` compiles your VHDL code and performs syntax and static semantics checks.
`xmelab`	Elaborates the design hierarchy and determines signal connectivity.
`xmsim`	Runs mixed-language simulation. This program is the simulation kernel that performs event scheduling and executes the simulation code.

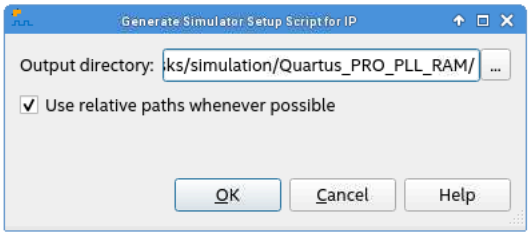
5.2. Generating Simulator Setup Script Templates

You can use simulator setup scripts to help you readily simulate IP cores in your design.

Follow these steps to generate the vendor-specific simulator setup script templates for the IP modules in your design. You can then customize these templates for your specific simulation goals.

1. To compile your design, click **Processing ➤ Start Compilation**. The Messages window indicates when compilation is complete.
2. Click **Tools ➤ Generate Simulator Setup Script for IP**.
3. Retain the default settings for the **Output directory** and also the **Use relative paths whenever possible** option.
4. To generate the setup script templates and vendor-specific sub-folders, including `xcelium/` and `common/` in the specified output directory, click **OK**.

Figure 16. Generate Simulator Setup Script for IP Dialog Box



5.3. Sourcing Cadence Xcelium Simulator Setup Scripts

1. The generated `xcelium/xmsim_setup.sh` simulation script contains the following template lines. Cut and paste these lines into a new top-level script, for example `xmsim.sh`. This new top-level script calls the generated simulation script, `xmsim_setup.sh`.

```
# # TOP-LEVEL TEMPLATE - BEGIN
# #
# # QSYS_SIMDIR is used in the Quartus-generated IP simulation script to
# # construct paths to the files required to simulate the IP in your Quartus
# # project. By default, the IP script assumes that you are launching the
# # simulator from the IP script location. If launching from another
# # location, set QSYS_SIMDIR to the output directory you specified when you
# # generated the IP script, relative to the directory from which you launch
# # the simulator. In this case, you must also copy the generated files
# # "cds.lib" and "hdl.var" - plus the directory "cds_libs" if generated -
# # into the location from which you launch the simulator, or incorporate
# # into any existing library setup.
# #
# # Run Quartus-generated IP simulation script once to compile Quartus EDA
# # simulation libraries and Quartus-generated IP simulation files, and copy
# # any ROM/RAM initialization files to the simulation directory.
# # - If necessary, specify any compilation options:
# #   USER_DEFINED_COMPILE_OPTIONS
# #   USER_DEFINED_VHDL_COMPILE_OPTIONS applied to vhdl compiler
# #   USER_DEFINED_VERILOG_COMPILE_OPTIONS applied to verilog compiler
# #
# source <script generation output directory>/xcelium/xcelium_setup.sh \
# SKIP_ELAB=1 \
# SKIP_SIM=1 \
# USER_DEFINED_COMPILE_OPTIONS=<compilation options for your design> \
# USER_DEFINED_VHDL_COMPILE_OPTIONS=<VHDL compilation options for your
design> \
# USER_DEFINED_VERILOG_COMPILE_OPTIONS=<Verilog compilation options for your
design> \
# QSYS_SIMDIR=<script generation output directory>
# #
# # Compile all design files and testbench files, including the top level.
# # (These are all the files required for simulation other than the files
# # compiled by the IP script)
# #
# xmvlog <compilation options> <design and testbench files>
# #
# # TOP_LEVEL_NAME is used in this script to set the top-level simulation or
# # testbench module/entity name.
# #
# # Run the IP script again to elaborate and simulate the top level:
# # - Specify TOP_LEVEL_NAME and USER_DEFINED_ELAB_OPTIONS.
# # - Override the default USER_DEFINED_SIM_OPTIONS. For example, to run
# #   until $finish(), set to an empty string: USER_DEFINED_SIM_OPTIONS="".
# #
```

```
# source <script generation output directory>/xcelium/xcelium_setup.sh \
# SKIP_FILE_COPY=1 \
# SKIP_DEV_COM=1 \
# SKIP_COM=1 \
# TOP_LEVEL_NAME=<simulation top> \
# USER_DEFINED_ELAB_OPTIONS=<elaboration options for your design> \
# USER_DEFINED_SIM_OPTIONS=<simulation options for your design>
# #
# # TOP-LEVEL TEMPLATE - END
```

2. Delete the first two characters of each line (comment and space):

```
 # TOP-LEVEL TEMPLATE - BEGIN
 #
 # QSYS_SIMDIR is used in the Quartus-generated IP simulation script to
 # construct paths to the files required to simulate the IP in your Quartus
 # project. By default, the IP script assumes that you are launching the
 # simulator from the IP script location. If launching from another
 # location, set QSYS_SIMDIR to the output directory you specified when you
 # generated the IP script, relative to the directory from which you launch
 # the simulator. In this case, you must also copy the generated files
 # "cds.lib" and "hdl.var" - plus the directory "cds_libs" if generated -
 # into the location from which you launch the simulator, or incorporate
 # into any existing library setup.
 #
 # Run Quartus-generated IP simulation script once to compile Quartus EDA
 # simulation libraries and Quartus-generated IP simulation files, and copy

 #   until $finish(), set to an empty string: USER_DEFINED_SIM_OPTIONS="".
 #
 source <script generation output directory>/xcelium/xcelium_setup.sh \
 SKIP_FILE_COPY=1 \
 SKIP_DEV_COM=1 \
 SKIP_COM=1 \
 TOP_LEVEL_NAME=<simulation top> \
 USER_DEFINED_ELAB_OPTIONS=<elaboration options for your design> \
 USER_DEFINED_SIM_OPTIONS=<simulation options for your design>
 #
 # TOP-LEVEL TEMPLATE - END
```

3. If necessary, add the QSYS_SIMDIR variable to point to the location of the generated IP simulation files. Specify any other changes that you require to match your design simulation requirements. The scripts offer variables to set compilation or simulation options. Refer to the generated script for details.
4. Refer to the following xmsim.sh example content, where this file is in the same /xcelium sub-folder as the xmsim_setup.sh file.

```
# TOP-LEVEL TEMPLATE - BEGIN
#
# QSYS_SIMDIR is used in the Quartus-generated IP simulation script to
# construct paths to the files required to simulate the IP in your Quartus
# project. By default, the IP script assumes that you are launching the
# simulator from the IP script location. If launching from another
# location, set QSYS_SIMDIR to the output directory you specified when you
# generated the IP script, relative to the directory from which you launch
# the simulator. In this case, you must also copy the generated files
# "cds.lib" and "hdl.var" - plus the directory "cds_libs" if generated -
# into the location from which you launch the simulator, or incorporate
# into any existing library setup.
#
# Run Quartus-generated IP simulation script once to compile Quartus EDA
# simulation libraries and Quartus-generated IP simulation files, and copy
# any ROM/RAM initialization files to the simulation directory.
# - If necessary, specify any compilation options:
#   USER_DEFINED_COMPILE_OPTIONS
#   USER_DEFINED_VHDL_COMPILE_OPTIONS applied to vhdl compiler
#   USER_DEFINED_VERILOG_COMPILE_OPTIONS applied to verilog compiler
#
source ./xcelium_setup.sh \
SKIP_ELAB=1 \
SKIP_SIM=1 \
USER_DEFINED_COMPILE_OPTIONS="" \
USER_DEFINED_VHDL_COMPILE_OPTIONS="" \
USER_DEFINED_VERILOG_COMPILE_OPTIONS="" \
QSYS_SIMDIR=./../
#
# Compile all design files and testbench files, including the top level.
# (These are all the files required for simulation other than the files
# compiled by the IP script)
#
xmvlog $QSYS_SIMDIR/PLL_RAM.v
xmvlog $QSYS_SIMDIR/UP_COUNTER_IP/UP_COUNTER_IP.v
xmvlog $QSYS_SIMDIR/DOWN_COUNTER_IP/DOWN_COUNTER_IP.v
xmvlog $QSYS_SIMDIR/ClockPLL/ClockPLL.v
xmvlog $QSYS_SIMDIR/RAMhub/RAMhub.v
xmvlog $QSYS_SIMDIR/testbench_1.v
#
# TOP_LEVEL_NAME is used in this script to set the top-level simulation or
# testbench module/entity name.
#
# Run the IP script again to elaborate and simulate the top level:
# - Specify TOP_LEVEL_NAME and USER_DEFINED_ELAB_OPTIONS.
# - Override the default USER_DEFINED_SIM_OPTIONS. For example, to run
#   until $finish(), set to an empty string: USER_DEFINED_SIM_OPTIONS="".
#
 source ./xcelium_setup.sh \
SKIP_FILE_COPY=1 \
SKIP_DEV_COM=1 \
SKIP_COM=1 \
TOP_LEVEL_NAME="tb" \
USER_DEFINED_ELAB_OPTIONS="-timescale\ 1ns/1ps\ -NOWARN\ CSINFI" \
USER_DEFINED_SIM_OPTIONS="-GUI"
#
# TOP-LEVEL TEMPLATE - END
```

5. Run the resulting top-level script by typing the following at the command-line:

```
sh xmsim.sh
```

Specify the path to this file if you run it from a different directory.

5.4. Cadence Xcelium Parallel Simulator Support Revision History

Document Version	Quartus Prime Version	Changes
2023.12.07	23.4	• Updated *Using the Command-Line Interface* topic to include `xrun` executable. • Added *Generating Simulator Setup Script Templates* topic. • Updated script content and steps in *Sourcing Cadence Xcelium Simulator Setup Scripts* topic. • Removed obsolete *Sourcing Cadence Incisive Simulator Setup Scripts* topic.
2022.04.13	22.1	• Revised name of Questa Intel FPGA Edition and QuestaSim for latest guidelines throughout.
2021.03.29	21.1	• Removed support for Cadence Incisive Enterprise* and removed document section.
2018.05.07	18.0	• Renamed chapter for Xcelium Parallel Simulator support. • Added Xcelium command-line support. • Updated commands in the Quick Start Example.

6. Quartus Prime Pro Edition User Guide Third-party Simulation Archive

For the latest and previous versions of this user guide, refer to Quartus Prime Pro Edition User Guide: Third-party Simulation. If an IP or software version is not listed, the user guide for the previous IP or software version applies.

A. Quartus Prime Pro Edition User Guides

Refer to the following user guides for comprehensive information on all phases of the Quartus Prime Pro Edition FPGA design flow.

Related Information

- Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Quartus Prime Pro Edition software, including managing Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

1. Siemens EDA Precision* RTL Synthesis Support

1.1. About Precision RTL Synthesis Support

This section describes Intel® Quartus® Prime software support for integration with the Siemens EDA Precision RTL Synthesis and Precision RTL Plus Synthesis software. This description includes the key design flows, methodologies, and techniques for improving your results for Intel devices by integrating Precision RTL Synthesis. This document assumes that you have appropriate installation and licensing of the Precision RTL software and the Intel Quartus Prime Pro Edition software.

To obtain and license the Precision Synthesis software and documentation, refer to the Siemens EDA website.

Related Information

Siemens EDA Precision RTL website

1.2. Precision RTL Integration Flow

The following steps describe a basic Intel Quartus Prime design flow integrating the Precision RTL synthesis software:

1. Create Verilog HDL or VHDL design files.
2. Create a project in the Precision RTL software that contains the HDL files for your design, select your target device, and set global constraints.
3. Compile the project in the Precision RTL software.
4. Add specific timing constraints, optimization attributes, and compiler directives to optimize the design during synthesis. With the design analysis and cross-probing capabilities of the Precision RTL software, you can identify and improve circuit area and performance issues using prelayout timing estimates.

   Note: For best results, Siemens EDA recommends specifying constraints that are as close as possible to actual operating requirements. Properly setting clock and I/O constraints, assigning clock domains, and indicating false and multicycle paths guide the synthesis algorithms more accurately toward a suitable solution in the shortest synthesis time.
5. Synthesize the project in the Precision RTL software.
6. Create an Intel Quartus Prime project and import the following files generated by the Precision RTL software into the Intel Quartus Prime project:

- The Verilog Quartus Mapping File (`.vqm`) netlist
- Synopsys Design Constraints File (`.sdc`) for Timing Analyzer constraints
- Tcl Script Files (`.tcl`) to set up your Intel Quartus Prime project and pass constraints

7. After obtaining place-and-route results that meet your requirements, configure or program the Intel device.

1.2.1. Timing Optimization

If your area or timing requirements are not met, you can change the constraints and resynthesize the design in the Precision RTL software, or you can change the constraints to optimize the design during place-and-route in the Intel Quartus Prime software. Repeat the process until the area and timing requirements are met.

You can use other options and techniques in the Intel Quartus Prime software to meet area and timing requirements. For example, the **WYSIWYG Primitive Resynthesis** option can perform optimizations on your EDIF netlist in the Intel Quartus Prime software.

While simulation and analysis can be performed at various points in the design process, final timing analysis should be performed after placement and routing is complete.

Related Information

- Netlist Optimizations and Physical Synthesis
- Timing Closure and Optimization

1.3. Intel Device Family Support

The Precision RTL software supports all FPGA device families available in the current version of the Intel Quartus Prime Pro Edition software. Support for newly released device families may require an overlay.

1.4. Precision RTL Generated Files

During synthesis, the Precision RTL software produces several intermediate and output files.

Table 1. Precision RTL Software Intermediate and Output Files

File Extension	File Description
`.psp`	Precision RTL Project File.
`.xdb`	Design Database File.
`.rep`(1)	Synthesis Area and Timing Report File.
	continued...

File Extension	File Description
`.vqm`[2]	Technology-specific netlist in `.vqm` file format.
`.tcl`	Forward-annotated Tcl assignments and constraints file. The *<project name>*`.tcl` file is generated for all devices. The `.tcl` file acts as the Intel Quartus Prime Project Configuration file and is used to make basic project and placement assignments, and to create and compile a Intel Quartus Prime project.
`.sdc`	Intel Quartus Prime timing constraints file in Synopsys Design Constraints format. This file is generated automatically if the device uses the Timing Analyzer by default in the Intel Quartus Prime software, and has the naming convention *<project name>*`_pnr_constraints .sdc`.

Related Information

Synthesizing the Design and Evaluating the Results on page 9

1.5. Creating and Compiling a Project in the Precision Synthesis Software

After creating your design files, create a project in the Precision RTL software that contains the basic settings for compiling the design.

1.6. Mapping the Design with Precision RTL

In the next steps, you set constraints and map the design to technology-specific cells. The Precision RTL software maps the design by default to the fastest possible implementation that meets your timing constraints. To accomplish this, you must specify timing requirements for the automatically determined clock sources. With this information, the Precision RTL software performs static timing analysis to determine the location of the critical timing paths. The Precision RTL software achieves the best results for your design when you set as many realistic constraints as possible. Be sure to set constraints for timing, mapping, false paths, multicycle paths, and other factors that control the structure of the implemented design.

Siemens EDA recommends creating an `.sdc` file and adding this file to the **Constraint Files** section of the **Project Files** list. You can create this file with a text editor, by issuing command-line constraint parameters, or by directing the Precision RTL software to generate the file automatically the first time you synthesize your design. By default, the Precision RTL software saves all timing constraints and attributes in two files: `precision_rtl.sdc` and `precision_tech.sdc`. The

(1) The timing report file includes performance estimates that are based on pre-place-and-route information. Use the f_{MAX} reported by the Intel Quartus Prime software after place-and-route for accurate post-place-and-route timing information. The area report file includes post-synthesis device resource utilization statistics that can differ from the resource usage after place-and-route due to black boxes or further optimizations performed during placement and routing. Use the device utilization reported by the Intel Quartus Prime software after place-and-route for final resource utilization results.

(2) The Precision RTL software-generated VQM file is supported by the Intel Quartus Prime software version 10.1 and later.

`precision_rtl.sdc` file contains constraints set on the RTL-level database (post-compilation) and the `precision_tech.sdc` file contains constraints set on the gate-level database (post- synthesis) located in the current implementation directory.

You can also enter constraints at the command line. After adding constraints at the command line, update the `.sdc` file with the `update constraint file` command. You can add constraints that change infrequently directly to the HDL source files with HDL attributes or pragmas.

Note: The Precision RTL `.sdc` file contains all the constraints for the Precision RTL project. For the Intel Quartus Prime software, placement constraints are written in a `.tcl` file and timing constraints for the Timing Analyzer are written in the Intel Quartus Prime `.sdc` file.

1.6.1. Setting Timing Constraints

The Precision RTL software uses timing constraints, based on the industry-standard `.sdc` file format, to deliver optimal results. Missing timing constraints can result in incomplete timing analysis and might prevent timing errors from being detected. The Precision RTL software provides constraint analysis prior to synthesis to ensure that designs are fully and accurately constrained. The *<project name>*`_pnr_constraints.sdc` file, which contains timing constraints in `.sdc` format, is generated by the Intel Quartus Prime software.

Note: Because the `.sdc` file format requires that timing constraints be set relative to defined clocks, you must specify your clock constraints before applying any other timing constraints.

You also can use multicycle path and false path assignments to relax requirements or exclude nodes from timing requirements, which can improve area utilization and allow the software optimizations to focus on the most critical parts of the design.

For details about the syntax of Synopsys Design Constraint commands, refer to the *Precision RTL Synthesis User's Manual* and the *Precision Synthesis Reference Manual*.

1.6.2. Setting Mapping Constraints

Mapping constraints affect how your design is mapped into the target Intel device. You can set mapping constraints in the user interface, in HDL code, or with the `set_attribute` command in the constraint file.

1.6.3. Assigning Pin Numbers and I/O Settings

The Precision RTL software supports assigning device pin numbers, I/O standards, drive strengths, and slew rate settings to top-level ports of the design. You can set these timing constraints with the `set_attribute` command, with the GUI, or by specifying synthesis attributes in your HDL code. These constraints are forward-annotated in the *<project name>*`.tcl` file that is read by the Intel Quartus Prime software during place-and-route and do not affect synthesis.

You can use the `set_attribute` command in the Precision RTL software `.sdc` file to specify pin number constraints, I/O standards, drive strengths, and slow slew-rate settings. The table below describes the format to use for entries in the Precision RTL software constraint file.

Table 2. Constraint File Settings

Constraint	Entry Format for Precision Constraint File
Pin number	`set_attribute -name PIN_NUMBER -value "<pin number>" -port <port name>`
I/O standard	`set_attribute -name IOSTANDARD -value "<I/O Standard>" -port <port name>`
Drive strength	`set_attribute -name DRIVE -value "<drive strength in mA>" -port <port name>`
Slew rate	`set_attribute -name SLEW -value "TRUE | FALSE" -port <port name>`

You also can use synthesis attributes or pragmas in your HDL code to make these assignments.

Example 1. Verilog HDL Pin Assignment

```
//pragma attribute clk pin_number P10;
```

Example 2. VHDL Pin Assignment

```
attribute pin_number : string
attribute pin_number of clk : signal is "P10";
```

You can use the same syntax to assign the I/O standard using the IOSTANDARD attribute, drive strength using the attribute DRIVE, and slew rate using the SLEW attribute.

For more details about attributes and how to set these attributes in your HDL code, refer to the *Precision RTL Reference Manual.*

1.6.4. Assigning I/O Registers

The Precision RTL software performs timing-driven I/O register mapping by default. You can force a register to the device IO element (IOE) using the Complex I/O constraint. This option does not apply if you turn off **I/O pad insertion.**

Note: You also can make the assignment by right-clicking on the pin in the Schematic Viewer.

1.6.5. Disabling I/O Pad Insertion

The Precision RTL software assigns I/O pad atoms (device primitives used to represent the I/O pins and I/O registers) to all ports in the top-level of a design by default. In certain situations, you might not want Precision RTL to add I/O pads to all I/O pins in the design. The Intel Quartus Prime software can compile a design without I/O pads; however, including I/O pads provides the Precision RTL software with more information about the top-level pins in the design.

1.6.5.1. Preventing the Precision RTL Software from Adding I/O Pads

If you are compiling a subdesign as a separate project, I/O pins cannot be primary inputs or outputs of the device; therefore, the I/O pins should not have an I/O pad associated with them.

To prevent the Precision RTL software from adding I/O pads:

- You can use the Precision RTL GUI or add the following command to the project file:

```
setup_design -addio=false
```

1.6.5.2. Preventing the Precision RTL Software from Adding an I/O Pad on an Individual Pin

To prevent I/O pad insertion on an individual pin when you are using a black box, such as DDR or a phase-locked loop (PLL), at the external ports of the design, perform the following steps:

1. Compile your design.
2. Use the Precision RTL GUI to select the individual pin and turn off I/O pad insertion.

Note: You also can make this assignment by attaching the `nopad` attribute to the port in the HDL source code.

1.6.6. Controlling Fan-Out on Data Nets

Fan-out is defined as the number of nodes driven by an instance or top-level port. High fan-out nets can cause significant delays that result in an unroutable net. On a critical path, high fan-out nets can cause longer delays in a single net segment that result in the timing constraints not being met. To prevent this behavior, each device family has a global fan-out value set in the Precision RTL software library. In addition, the Intel Quartus Prime software automatically routes high fan-out signals on global routing lines in the Intel device whenever possible.

To eliminate routability and timing issues associated with high fan-out nets, the Precision RTL software also allows you to override the library default value on a global or individual net basis. You can override the library value by setting a `max_fanout` attribute on the net.

1.7. Synthesizing the Design and Evaluating the Results

During synthesis, the Precision RTL software optimizes the compiled design, and then writes out netlists and reports to the implementation subdirectory of your working directory after the implementation is saved, using the following naming convention:

`<project name>_impl_<number>`

After synthesis is complete, you can evaluate the results for area and timing. The *Precision RTL Synthesis User's Manual* describes different results that can be evaluated in the software.

There are several schematic viewers available in the Precision RTL software: RTL schematic, Technology-mapped schematic, and Critical Path schematic. These analysis tools allow you to quickly and easily isolate the source of timing or area issues, and to make additional constraint or code changes to optimize the design.

1.7.1. Obtaining Accurate Logic Utilization and Timing Analysis Reports

Historically, designers have relied on post-synthesis logic utilization and timing reports to determine the amount of logic their design requires, the size of the device required, and how fast the design runs. However, today's FPGA devices provide a wide variety of advanced features in addition to basic registers and look-up tables (LUTs). The Intel Quartus Prime software has advanced algorithms to take advantage of these features, as well as optimization techniques to increase performance and reduce the amount of logic required for a given design. In addition, designs can contain black boxes and functions that take advantage of specific device features. Because of these advances, synthesis tool reports provide post-synthesis area and timing estimates, but you should use the place-and-route software to obtain final logic utilization and timing reports.

1.8. Guidelines for Intel FPGA IP Cores and Architecture-Specific Features

Intel provides parameterizable IP cores, including the LPMs, and device-specific Intel FPGA IP, and IP available through third-party partners. You can use IP cores by instantiating them in your HDL code or by inferring certain functions from generic HDL code.

If you want to instantiate an IP core such as a PLL in your HDL code, you can instantiate and parameterize the function using the port and parameter definitions, or you can customize a function with the parameter editor. Intel recommends using the IP Catalog and parameter editor, which provides a graphical interface within the Intel Quartus Prime software for customizing and parameterizing any available IP core for the design.

The Precision RTL software automatically recognizes certain types of HDL code and infers the appropriate IP core.

Related Information

- Inferring Intel FPGA IP Cores from HDL Code on page 13
- Recommended HDL Coding Styles, Design Recommendations User Guide

1.8.1. Instantiating IP Cores With IP Catalog-Generated Verilog HDL Files

The IP Catalog generates a Verilog HDL instantiation template file <*output file*>_inst.v and a hollow-body black box module declaration <*output file*>_bb.v for use in your Precision RTL design. Incorporate the instantiation template file, <*output file*>_inst.v, into your top-level design to instantiate the IP core wrapper file, <*output file*>.v.

Include the hollow-body black box module declaration <*output file*>_bb.v in your Precision RTL project to describe the port connections of the black box. Adding the IP core wrapper file <*output file*>.v in your Precision RTL project is optional, but you must add it to your Intel Quartus Prime project along with the Precision RTL generated EDIF or VQM netlist.

Alternatively, you can include the IP core wrapper file <*output file*>.v in your Precision RTL project and turn on the **Exclude file from Compile Phase** option in the Precision RTL software to exclude the file from compilation and to copy the file to the appropriate directory for use by the Intel Quartus Prime software during place-and-route.

1.8.2. Instantiating IP Cores With IP Catalog-Generated VHDL Files

The IP Catalog generates a VHDL component declaration file <*output file*>.cmp and a VHDL instantiation template file <*output file*>_inst.vhd for use in your Precision RTL design. Incorporate the component declaration and instantiation template into your top-level design to instantiate the IP core wrapper file, <*output file*>.vhd.

Adding the IP core wrapper file <*output file*>.vhd in your Precision RTL project is optional, but you must add the file to your Intel Quartus Prime project along with the Precision RTL-generated EDIF or VQM netlist.

Alternatively, you can include the IP core wrapper file <*output file*>.v in your Precision RTL project and turn on the **Exclude file from Compile Phase** option in the Precision RTL software to exclude the file from compilation and to copy the file to the appropriate directory for use by the Intel Quartus Prime software during place-and-route.

1.8.3. Instantiating Intellectual Property With the IP Catalog and Parameter Editor

Many Intel FPGA IP functions include a resource and timing estimation netlist that the Precision RTL software can use to synthesize and optimize logic around the IP efficiently. As a result, the Precision RTL software provides better timing correlation, area estimates, and Quality of Results (QoR) than a black box approach.

To create this netlist file, perform the following steps:

1. Select the IP function in the IP Catalog.
2. Click **Next** to open the Parameter Editor.
3. Click **Set Up Simulation**, which sets up all the EDA options.
4. Turn on the **Generate netlist** option to generate a netlist for resource and timing estimation and click **OK**.
5. Click **Generate** to generate the netlist file.

The Intel Quartus Prime software generates a file <*output file*>_syn.v. This netlist contains the "gray box" information for resource and timing estimation, but does not contain the actual implementation. Include this netlist file into your Precision RTL project as an input file. Then include the IP core wrapper file <*output file*>.v|vhd in the Intel Quartus Prime project along with your EDIF or VQM output netlist.

The generated "gray box" netlist file, <*output file*>_syn.v , is always in Verilog HDL format, even if you select VHDL as the output file format.

1.8.4. Instantiating Black Box IP Functions With Generated Verilog HDL Files

You can use the `syn_black_box` or `black_box` compiler directives to declare a module as a black box. The top-level design files must contain the IP port mapping and a hollow-body module declaration. You can apply the directive to the module declaration in the top-level file or a separate file included in the project so that the Precision RTL software recognizes the module is a black box.

Note: The `syn_black_box` and `black_box` directives are supported only on module or entity definitions.

The example below shows a sample top-level file that instantiates `my_verilogIP.v`, which is a simplified customized variation generated by the IP Catalog and Parameter Editor.

Example 3. Top-Level Verilog HDL Code with Black Box Instantiation of IP

```
module top (clk, count);
   input clk;
   output[7:0] count;

   my_verilogIP verilogIP_inst (.clock (clk), .q (count));
endmodule

// Module declaration
// The following attribute is added to create a
// black box for this module.
module my_verilogIP (clock, q) /* synthesis syn_black_box */;
   input clock;
   output[7:0] q;
endmodule
```

1.8.5. Instantiating Black Box IP Functions With Generated VHDL Files

You can use the `syn_black_box` or `black_box` compiler directives to declare a component as a black box. The top-level design files must contain the IP core variation component declaration and port mapping. Apply the directive to the component declaration in the top-level file.

Note: The `syn_black_box` and `black_box` directives are supported only on module or entity definitions.

The example below shows a sample top-level file that instantiates `my_vhdlIP.vhd`, which is a simplified customized variation generated by the IP Catalog and Parameter Editor.

Example 4. Top-Level VHDL Code with Black Box Instantiation of IP

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
ENTITY top IS
  PORT (
    clk: IN STD_LOGIC ;
    count: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
  );
END top;

ARCHITECTURE rtl OF top IS
  COMPONENT my_vhdlIP
```

```
  PORT (
    clock: IN STD_LOGIC ;
    q: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
  );
  end COMPONENT;
  attribute syn_black_box : boolean;
  attribute syn_black_box of my_vhdlIP: component is true;
  BEGIN
    vhdlIP_inst : my_vhdlIP PORT MAP (
       clock => clk,
       q => count
    );
END rtl;
```

1.8.6. Inferring Intel FPGA IP Cores from HDL Code

The Precision RTL software automatically recognizes certain types of HDL code and maps arithmetical operators, relational operators, and memory (RAM and ROM), to technology-specific implementations. This functionality allows technology-specific resources to implement these structures by inferring the appropriate Intel function to provide optimal results. In some cases, the Precision RTL software has options that you can use to disable or control inference.

For coding style recommendations and examples for inferring technology-specific architecture in Intel devices, refer to the *Precision RTL Synthesis Style Guide*.

Related Information

Recommended HDL Coding Styles, Design Recommendations User Guide

1.8.6.1. Multipliers

The Precision RTL software detects multipliers in HDL code and maps them directly to device atoms to implement the multiplier in the appropriate type of logic. The Precision RTL software also allows you to control the device resources that are used to implement individual multipliers.

1.8.6.1.1. Controlling DSP Block Inference for Multipliers

By default, the Precision RTL software uses DSP blocks available in devices to implement multipliers. The default setting is **AUTO**, which allows the Precision RTL software to map to logic look-up tables (LUTs) or DSP blocks, depending on the size of the multiplier. You can use the Precision RTL GUI or HDL attributes for direct mapping to only logic elements or to only DSP blocks.

Table 3. Options for dedicated_mult Parameter to Control Multiplier Implementation in Precision RTL

Value	Description
ON	Use only DSP blocks to implement multipliers, regardless of the size of the multiplier.
OFF	Use only logic (LUTs) to implement multipliers, regardless of the size of the multiplier.
AUTO	Use logic (LUTs) or DSP blocks to implement multipliers, depending on the size of the multipliers.

1.8.6.2. Setting the Use Dedicated Multiplier Option

To set the `Use Dedicated Multiplier` option in the Precision RTL GUI, compile the design, and then in the Design Hierarchy browser, right-click the operator for the desired multiplier and click **Use Dedicated Multiplier**.

1.8.6.3. Setting the dedicated_mult Attribute

To control the implementation of a multiplier in your HDL code, use the `dedicated_mult` attribute with the appropriate value as shown in the examples below.

Example 5. Setting the dedicated_mult Attribute in Verilog HDL

```
//synthesis attribute <signal name> dedicated_mult <value>
```

Example 6. Setting the dedicated_mult Attribute in VHDL

```
ATTRIBUTE dedicated_mult: STRING;
ATTRIBUTE dedicated_mult OF <signal name>: SIGNAL IS <value>;
```

The `dedicated_mult` attribute can be applied to signals and wires; it does not work when applied to a register. This attribute can be applied only to simple multiplier code, such as `a = b * c`.

Some signals for which the `dedicated_mult` attribute is set can be removed during synthesis by the Precision RTL software for design optimization. In such cases, if you want to force the implementation, you should preserve the signal by setting the `preserve_signal` attribute to TRUE.

Example 7. Setting the preserve_signal Attribute in Verilog HDL

```
//synthesis attribute <signal name> preserve_signal TRUE
```

Example 8. Setting the preserve_signal Attribute in VHDL

```
ATTRIBUTE preserve_signal: BOOLEAN;
ATTRIBUTE preserve_signal OF <signal name>: SIGNAL IS TRUE;
```

Example 9. Verilog HDL Multiplier Implemented in Logic

```
module unsigned_mult (result, a, b);
   output [15:0] result;
   input [7:0] a;
   input [7:0} b;
   assign result = a * b;
   //synthesis attribute result dedicated_mult OFF
endmodule
```

Example 10. VHDL Multiplier Implemented in Logic

```
LIBRARY ieee;
USE ieee.std_logic_1164.ALL;
USE ieee.std_logic_arith.ALL;
USE ieee.std_logic_unsigned.ALL;

ENTITY unsigned_mult IS
   PORT(
      a: IN std_logic_vector (7 DOWNTO 0);
      b: IN std_logic_vector (7 DOWNTO 0);
      result: OUT std_logic_vector (15 DOWNTO 0));
ATTRIBUTE dedicated_mult: STRING;
END unsigned_mult;

ARCHITECTURE rtl OF unsigned_mult IS
   SIGNAL a_int, b_int: UNSIGNED (7 downto 0);
   SIGNAL pdt_int: UNSIGNED (15 downto 0);
ATTRIBUTE dedicated_mult OF pdt_int: SIGNAL IS "OFF;
```

```
BEGIN
   a_int <= UNSIGNED (a);
   b_int <= UNSIGNED (b);
   pdt_int <= a_int * b_int;
   result <= std_logic_vector(pdt_int);
END rtl;
```

1.8.6.4. Inferring Multiplier-Accumulators and Multiplier-Adders

The Precision RTL software also allows you to control the device resources used to implement multiply-accumulators or multiply-adders in your project or in a particular module.

The Precision RTL software detects multiply-accumulators or multiply-adders in HDL code and infers an ALTMULT_ACCUM or ALTMULT_ADD IP cores so that the logic can be placed in DSP blocks, or the software maps these functions directly to device atoms to implement the multiplier in the appropriate type of logic.

Note: The Precision RTL software supports inference for these functions only if the target device family has dedicated DSP blocks.

For more information about DSP blocks in Intel devices, refer to the appropriate Intel FPGA device family documentation.

For more information about inferring multiply-accumulator and multiply-adder IP cores in HDL code, refer to the Intel *Recommended HDL Coding Styles* and the Siemens EDA *Precision RTL Synthesis Style Guide*.

Related Information

Intel Quartus Prime Pro Edition User Guide: Design Recommendations

1.8.6.5. Controlling DSP Block Inference

By default, the Precision RTL software infers the ALTMULT_ADD or ALTMULT_ACCUM IP cores appropriately in your design. These IP cores allow the Intel Quartus Prime software to select either logic or DSP blocks, depending on the device utilization and the size of the function.

You can use the `extract_mac` attribute to prevent inference of an ALTMULT_ADD or ALTMULT_ACCUM IP cores in a certain module or entity.

Table 4. Options for extract_mac Attribute Controlling DSP Implementation

Value	Description
TRUE	The ALTMULT_ADD or ALTMULT_ACCUM IP core is inferred.
FALSE	The ALTMULT_ADD or ALTMULT_ACCUM IP core is not inferred.

To control inference, use the `extract_mac` attribute with the appropriate value from the examples below in your HDL code.

Example 11. Setting the extract_mac Attribute in Verilog HDL

```
//synthesis attribute <module name> extract_mac <value>
```

Example 12. Setting the extract_mac Attribute in VHDL

```
ATTRIBUTE extract_mac: BOOLEAN;
ATTRIBUTE extract_mac OF <entity name>: ENTITY IS <value>;
```

To control the implementation of the multiplier portion of a multiply-accumulator or multiply-adder, you must use the `dedicated_mult` attribute.

You can use the `extract_mac`, `dedicated_mult`, and `preserve_signal` attributes (in Verilog HDL and VHDL) to implement the given DSP function in logic in the Intel Quartus Prime software.

Example 13. Using extract_mac, dedicated_mult, and preserve_signal in Verilog HDL

```
module unsig_altmult_accuml (dataout, dataa, datab, clk, aclr, clken);
   input [7:0} dataa, datab;
   input clk, aclr, clken;
   output [31:0] dataout;

   reg    [31:0] dataout;
   wire   [15:0] multa;
   wire   [31:0] adder_out;

   assign multa = dataa * datab;

   //synthesis attribute multa preserve_signal TRUE
   //synthesis attribute multa dedicated_mult OFF
   assign adder_out = multa + dataout;

   always @ (posedge clk or posedge aclr)
   begin
      if (aclr)
      dataout <= 0;
      else if (clken)
      dataout <= adder_out;
   end

   //synthesis attribute unsig_altmult_accuml extract_mac FALSE
endmodule
```

Example 14. Using extract_mac, dedicated_mult, and preserve_signal in VHDL

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_arith.all;
USE ieee.std_logic_signed.all;
ENTITY signedmult_add IS
   PORT(
      a, b, c, d: IN STD_LOGIC_VECTOR (7 DOWNTO 0);
      result: OUT STD_LOGIC_VECTOR (15 DOWNTO 0));
   ATTRIBUTE preserve_signal: BOOLEANS;
   ATTRIBUTE dedicated_mult: STRING;
   ATTRIBUTE extract_mac: BOOLEAN;
   ATTRIBUTE extract_mac OF signedmult_add: ENTITY IS FALSE;
END signedmult_add;
ARCHITECTURE rtl OF signedmult_add IS
   SIGNAL a_int, b_int, c_int, d_int : signed (7 DOWNTO 0);
   SIGNAL pdt_int, pdt2_int : signed (15 DOWNTO 0);
   SIGNAL result_int: signed (15 DOWNTO 0);
   ATTRIBUTE preserve_signal OF pdt_int: SIGNAL IS TRUE;
   ATTRIBUTE dedicated_mult OF pdt_int: SIGNAL IS "OFF";
   ATTRIBUTE preserve_signal OF pdt2_int: SIGNAL IS TRUE;
   ATTRIBUTE dedicated_mult OF pdt2_int: SIGNAL IS "OFF";
BEGIN
   a_int <= signed (a);
   b_int <= signed (b);
```

```
   c_int <= signed (c);
   d_int <= signed (d);
   pdt_int <= a_int * b_int;
   pdt2_int <= c_int * d_int;
   result_int <= pdt_int + pdt2_int;
   result <= STD_LOGIC_VECTOR(result_int);
END rtl;
```

1.8.6.6. Inferring RAM and ROM

The Precision RTL software detects memory structures in HDL code and converts them to an operator that infers an ALTSYNCRAM or LPM_RAM_DP IP cores, depending on the device family. The Intel Quartus Prime software then places these functions in memory blocks.

The Precision RTL software supports inference for these functions only if the target Intel FPGA device family has dedicated memory blocks.

For more information about inferring RAM and ROM IP cores in HDL code, refer to the *Precision RTL Synthesis Style Guide*.

1.9. Siemens EDA Precision* RTL Synthesis Support Revision History

Document Version	Intel Quartus Prime Version	Changes
2023.12.12	23.4	• Added Top FAQs navigation to document cover. • Updated vendor and software product names throughout. • Removed obsolete Intel Quartus Prime Standard Edition and Altera references.
2022.03.28	18.1	Revised linking to documentation archives.
2018.09.24	18.1	Removed reference to obsolete .edf file from "Design Flow" diagram.
2018.05.07	18.0	Corrected trademark symbols on tool names.
2016.10.31	16.1	• Implemented Intel rebranding.

2. Synopsys Synplify* Support

2.1. About Synplify Support

the Intel Quartus Prime software supports use of the Synopsys Synplify software design flows, methodologies, and techniques for achieving optimal results in Intel devices. Synplify support applies to Synplify, Synplify Pro, and Synplify Premier software. This document assumes proper set up, licensing, and basic familiarity with the Synplify software.

This document covers the following information:

- General design flow with the Synplify and Intel Quartus Prime software.
- Synplify software optimization strategies, including timing-driven compilation settings, optimization options, and other attributes.
- Guidelines for use of Quartus Prime IP cores, including guidelines for HDL inference of IP cores.

Related Information

- Synplify Synthesis Techniques with the Intel Quartus Prime Software online training
- Synplify Pro Tips and Tricks online training

2.2. Synplify Software Integration Flow

The following steps describe a basic Intel Quartus Prime software flow integrating the Synplify software:

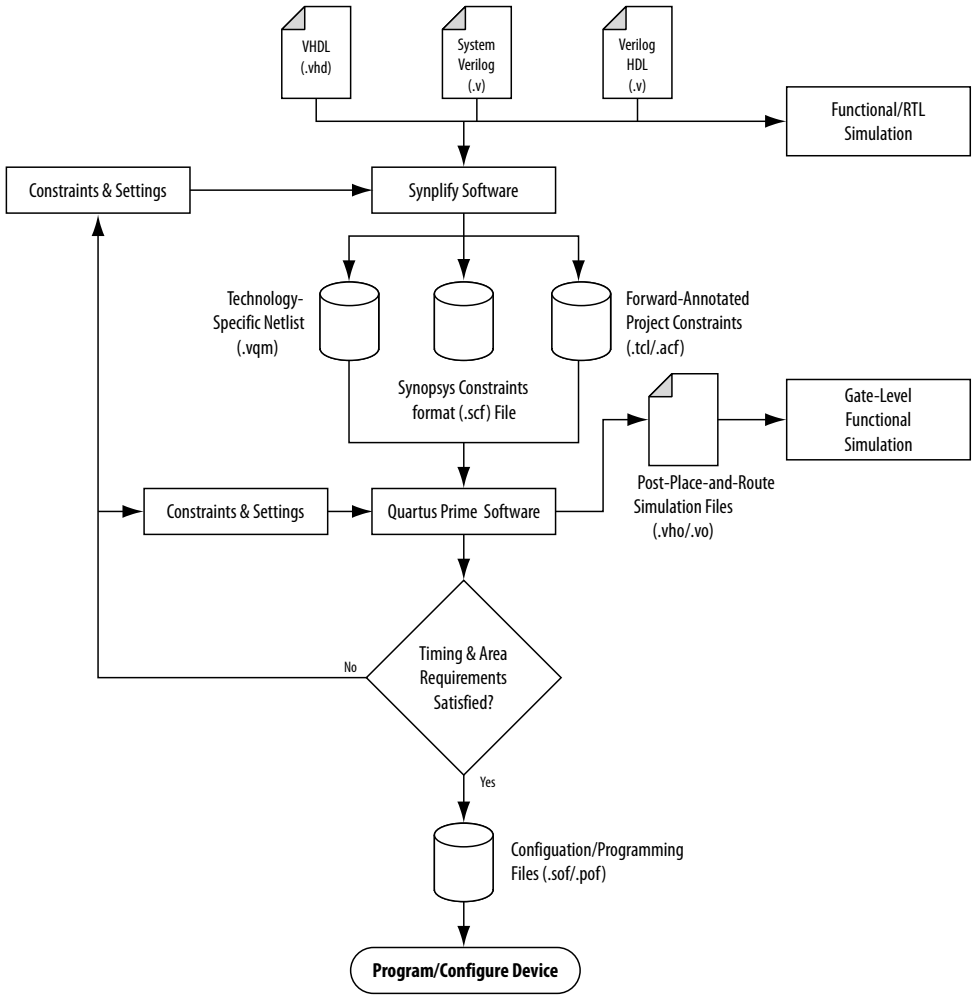
1. Create Verilog HDL (`.v`) or VHDL (`.vhd`) design files.
2. Set up a project in the Synplify software and add the HDL design files for synthesis.
3. Select a target device and add timing constraints and compiler directives in the Synplify software to help optimize the design during synthesis.
4. Synthesize the project in the Synplify software.
5. Create an Intel Quartus Prime project and import the following files generated by the Synplify software into the Intel Quartus Prime software. Use the following files for placement and routing, and for performance evaluation:

- Verilog Quartus Mapping File (`.vqm`) netlist.
- The Synopsys Constraints Format (`.scf`) file for Timing Analyzer constraints.
- The `.tcl` file to set up your Intel Quartus Prime project and pass constraints.

  Note: Alternatively, you can run the Intel Quartus Prime software from within the Synplify software.

6. After obtaining place-and-route results that meet your requirements, configure or program the Intel device.

Figure 1. Recommended Design Flow



Related Information

- Synplify Software Generated Files on page 20
- Design Constraints Support on page 21

2.3. Hardware Description Language Support

The Synplify software supports VHDL, Verilog HDL, and SystemVerilog source files. However, only the Synplify Pro and Premier software support mixed synthesis, allowing a combination of VHDL and Verilog HDL or SystemVerilog format source files.

The HDL Analyst that is included in the Synplify software is a graphical tool for generating schematic views of the technology-independent RTL view netlist (`.srs`) and technology-view netlist (`.srm`) files. You can use the Synplify HDL Analyst to analyze and debug your design visually. The HDL Analyst supports cross-probing between the RTL and Technology views, the HDL source code, the Finite State Machine (FSM) viewer, and between the technology view and the timing report file in the Intel Quartus Prime software. A separate license file is required to enable the HDL Analyst in the Synplify software. The Synplify Pro and Premier software include the HDL Analyst.

Related Information

Guidelines for Intel FPGA IP Cores and Architecture-Specific Features on page 30

2.4. Intel Device Family Support

Support for newly released device families may require an overlay. Contact Synopsys for more information.

Related Information

Synopsys Website

2.5. Tool Setup

2.5.1. Specifying the Intel Quartus Prime Software Version

You can specify your version of the Intel Quartus Prime software in **Implementation Options** in the Synplify software. This option ensures that the netlist is compatible with the software version and supports the newest features. Intel recommends using the latest version of the Intel Quartus Prime software whenever possible. If your Intel Quartus Prime software version is newer than the versions available in the **Quartus Version** list, check if there is a newer version of the Synplify software available that supports the current Intel Quartus Prime software version. Otherwise, select the latest version in the list for the best compatibility.

Note: The **Quartus Version** list is available only after selecting an Intel device.

Example 15. Specifying Intel Quartus Prime Software Version at the Command Line

```
set_option -quartus_version <version number>
```

2.6. Synplify Software Generated Files

During synthesis, the Synplify software produces several intermediate and output files.

Table 5. Synplify Intermediate and Output Files

File Extensions	File Description
.vqm	Technology-specific netlist in .vqm file format. A .vqm file is created for all Intel device families supported by the Intel Quartus Prime software.
.scf	Synopsys Constraint Format file containing timing constraints for the Timing Analyzer.
.tcl	Forward-annotated constraints file containing constraints and assignments. A .tcl file for the Intel Quartus Prime software is created for all devices. The .tcl file contains the appropriate Tcl commands to create and set up an Intel Quartus Prime project and pass placement constraints.
.srs	Technology-independent RTL netlist file that can be read only by the Synplify software.
.srm	Technology view netlist file.
.acf	Assignment and Configurations file for backward compatibility with the MAX+PLUS II software. For devices supported by the MAX+PLUS II software, the MAX+PLUS II assignments are imported from the MAX+PLUS II .acf file.
.srr(3)	Synthesis Report file.

Related Information

Synplify Software Integration Flow on page 18

2.7. Design Constraints Support

You can specify timing constraints and attributes by using the SCOPE window of the Synplify software, by editing the .sdc file, or by defining the compiler directives in the HDL source file. The Synplify software forward-annotates many of these constraints to the Intel Quartus Prime software.

After synthesis is complete, do the following steps:

1. Import the .vqm netlist to the Intel Quartus Prime software for place-and-route.
2. Use the .tcl file generated by the Synplify software to forward-annotate your project constraints including device selection. The .tcl file calls the generated .scf to forward-annotate Timing Analyzer timing constraints.

Related Information

- Synplify Software Integration Flow on page 18
- Synplify Optimization Strategies on page 23

(3) This report file includes performance estimates that are often based on pre-place-and-route information. Use the f_{MAX} reported by the Intel Quartus Prime software after place-and-route—it is the only reliable source of timing information. This report file includes post-synthesis device resource utilization statistics that might inaccurately predict resource usage after place-and-route. The Synplify software does not account for black box functions nor for logic usage reduction achieved through register packing performed by the Intel Quartus Prime software. Register packing combines a single register and look-up table (LUT) into a single logic cell, reducing logic cell utilization below the Synplify software estimate. Use the device utilization reported by the Intel Quartus Prime software after place-and-route.

2.7.1. Running the Intel Quartus Prime Software Manually With the Synplify-Generated Tcl Script

You can run the Intel Quartus Prime software with a Synplify-generated Tcl script.

To run the Tcl script to set up your project assignments, perform the following steps:

1. Ensure the `.vqm`, `.scf`, and `.tcl` files are located in the same directory.
2. In the Intel Quartus Prime software, on the View menu, point to and click **Tcl Console**. The Intel Quartus Prime Tcl Console opens.
3. At the Tcl Console command prompt, type the following:

```
source <path>/<project name>_cons.tcl
```

2.7.2. Passing Timing Analyzer SDC Timing Constraints to the Intel Quartus Prime Software

The Timing Analyzer is a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry standard constraints format, Synopsys Design Constraints (`.sdc`).

The Synplify-generated `.tcl` file contains constraints for the Intel Quartus Prime software, such as the device specification and any location constraints. Timing constraints are forward-annotated in the Synopsys Constraints Format (`.scf`) file.

Note: Synopsys recommends that you modify constraints using the SCOPE constraint editor window, rather than using the generated `.sdc`, `.scf`, or `.tcl` file.

The following list of Synplify constraints are converted to the equivalent Intel Quartus Prime SDC commands and are forward-annotated to the Intel Quartus Prime software in the `.scf` file:

- `define_clock`
- `define_input_delay`
- `define_output_delay`
- `define_multicycle_path`
- `define_false_path`

All Synplify constraints described above are mapped to SDC commands for the Timing Analyzer.

For syntax and arguments for these commands, refer to the applicable topic in this manual or refer to Synplify Help. For a list of corresponding commands in the Intel Quartus Prime software, refer to the Intel Quartus Prime Help.

Related Information

Timing-Driven Synthesis Settings on page 24

2.7.2.1. Individual Clocks and Frequencies

Specify clock frequencies for individual clocks in the Synplify software with the `define_clock` command. This command is passed to the Intel Quartus Prime software with the `create_clock` command.

2.7.2.2. Input and Output Delay

Specify input delay and output delay constraints in the Synplify software with the `define_input_delay` and `define_output_delay` commands, respectively. These commands are passed to the Intel Quartus Prime software with the `set_input_delay` and `set_output_delay` commands.

2.7.2.3. Multicycle Path

Specify a multicycle path constraint in the Synplify software with the `define_multicycle_path` command. This command is passed to the Intel Quartus Prime software with the `set_multicycle_path` command.

2.7.2.4. False Path

Specify a false path constraint in the Synplify software with the `define_false_path` command. This command is passed to the Intel Quartus Prime software with the `set_false_path` command.

2.8. Simulation and Formal Verification

You can perform simulation and formal verification at various stages in the design process. You can perform final timing analysis after placement and routing is complete.

If area and timing requirements are satisfied, use the files generated by the Intel Quartus Prime software to program or configure the Intel device. If your area or timing requirements are not met, you can change the constraints in the Synplify software or the Intel Quartus Prime software and rerun synthesis. Intel recommends that you provide timing constraints in the Synplify software and any placement constraints in the Intel Quartus Prime software. Repeat the process until area and timing requirements are met.

You can also use other options and techniques in the Intel Quartus Prime software to meet area and timing requirements, such as WYSIWYG Primitive Resynthesis, which can perform optimizations on your `.vqm` netlist within the Intel Quartus Prime software.

Note: In some cases, you might be required to modify the source code if the area and timing requirements cannot be met using options in the Synplify and Intel Quartus Prime software.

2.9. Synplify Optimization Strategies

Combining Synplify software constraints with VHDL and Verilog HDL coding techniques and Intel Quartus Prime software options can help you obtain the results that you require.

For more information about applying attributes, refer to the *Synopsys FPGA Synthesis Reference Manual*.

Related Information

Design Constraints Support on page 21

2.9.1. Using Synplify Premier to Optimize Your Design

Compared to other Synplify products, the Synplify Premier software offers additional physical synthesis optimizations. After typical logic synthesis, the Synplify Premier software places and routes the design and attempts to restructure the netlist based on the physical location of the logic in the Intel device. The Synplify Premier software forward-annotates the design netlist to the Intel Quartus Prime software to perform the final placement and routing. In the default flow, the Synplify Premier software also forward-annotates placement information for the critical path(s) in the design, which can improve the compilation time in the Intel Quartus Prime software.

The physical location annotation file is called <*design name*>`_plc.tcl`. If you open the Intel Quartus Prime software from the Synplify Premier software user interface, the Intel Quartus Prime software automatically uses this file for the placement information.

The Physical Analyst allows you to examine the placed netlist from the Synplify Premier software, which is similar to the HDL Analyst for a logical netlist. You can use this display to analyze and diagnose potential problems.

2.9.2. Using Implementations in Synplify Pro or Premier

You can create different synthesis results without overwriting the existing results, in the Synplify Pro or Premier software, by creating a new implementation from the Project menu. For each implementation, specify the target device, synthesis options, and constraint files. Each implementation generates its own subdirectory that contains all the resulting files, including `.vqm`, `.scf`, and `.tcl` files, from a compilation of the particular implementation. You can then compare the results of the different implementations to find the optimal set of synthesis options and constraints for a design.

2.9.3. Timing-Driven Synthesis Settings

The Synplify software supports timing-driven synthesis with user-assigned timing constraints to optimize the performance of the design.

The Intel Quartus Prime NativeLink feature allows timing constraints that are applied in the Synplify software to be forward-annotated for the Intel Quartus Prime software with an `.scf` file for timing-driven place and route.

The Synplify Synthesis Report File (`.srr`) contains timing reports of estimated place-and-route delays. The Intel Quartus Prime software can perform further optimizations on a post-synthesis netlist from third-party synthesis tools. In addition, designs might contain black boxes or intellectual property (IP) functions that have not been optimized by the third-party synthesis software. Actual timing results are obtained only after the design has been fully placed and routed in the Intel Quartus Prime software. For these reasons, the Intel Quartus Prime post place-and-route timing reports provide a more accurate representation of the design. Use the statistics in these reports to evaluate design performance.

Related Information

Passing Timing Analyzer SDC Timing Constraints to the Intel Quartus Prime Software on page 22

2.9.3.1. Clock Frequencies

For single-clock designs, you can specify a global frequency when using the push-button flow. While this flow is simple and provides good results, it often does not meet the performance requirements for more advanced designs. You can use timing constraints, compiler directives, and other attributes to help optimize the performance of a design. You can enter these attributes and directives directly in the HDL code. Alternatively, you can enter attributes (not directives) into an `.sdc` file with the SCOPE window in the Synplify software.

Use the SCOPE window to set global frequency requirements for the entire design and individual clock settings. Use the **Clocks** tab in the SCOPE window to specify frequency (or period), rise times, fall times, duty cycle, and other settings. Assigning individual clock settings, rather than over-constraining the global frequency, helps the Intel Quartus Prime software and the Synplify software achieve the fastest clock frequency for the overall design. The `define_clock` attribute assigns clock constraints.

2.9.3.2. Multiple Clock Domains

The Synplify software can perform timing analysis on unrelated clock domains. Each clock group is a different clock domain and is treated as unrelated to the clocks in all other clock groups. All clocks in a single clock group are assumed to be related, and the Synplify software automatically calculates the relationship between the clocks. You can assign clocks to a new clock group or put related clocks in the same clock group with the **Clocks** tab in the SCOPE window, or with the `define_clock` attribute.

2.9.3.3. Input and Output Delays

Specify the input and output delays for the ports of a design in the **Input/Output** tab of the SCOPE window, or with the `define_input_delay` and `define_output_delay` attributes. The Synplify software does not allow you to assign the t_{CO} and t_{SU} values directly to inputs and outputs. However, a t_{CO} value can be inferred by setting an external output delay; a t_{SU} value can be inferred by setting an external input delay.

Relationship Between t_{CO} and the Output Delay
t_{CO} = clock period – external output delay

Relationship Between t_{SU} and the Input Delay
t_{SU} = clock period – external input delay

When the `syn_forward_io_constraints` attribute is set to 1, the Synplify software passes the external input and output delays to the Intel Quartus Prime software using NativeLink integration. The Intel Quartus Prime software then uses the external delays to calculate the maximum system frequency.

2.9.3.4. Multicycle Paths

A multicycle path is a path that requires more than one clock cycle to propagate. Specify any multicycle paths in the design in the **Multi-Cycle Paths** tab of the SCOPE window, or with the `define_multicycle_path` attribute. You should specify which paths are multicycle to prevent the Intel Quartus Prime and the Synplify compilers from working excessively on a non-critical path. Not specifying these paths can also result in an inaccurate critical path reported during timing analysis.

2.9.3.5. False Paths

False paths are paths that should be ignored during timing analysis, or should be assigned low (or no) priority during optimization. Some examples of false paths include slow asynchronous resets, and test logic that has been added to the design. Set these paths in the **False Paths** tab of the SCOPE window, or use the `define_false_path` attribute.

2.9.4. FSM Compiler

If the FSM Compiler is turned on, the compiler automatically detects state machines in a design, which are then extracted and optimized. The FSM Compiler analyzes state machines and implements sequential, gray, or one-hot encoding, based on the number of states. The compiler also performs unused-state analysis, optimization of unreachable states, and minimization of transition logic. Implementation is based on the number of states, regardless of the coding style in the HDL code.

If the FSM Compiler is turned off, the compiler does not optimize logic as state machines. The state machines are implemented as HDL code. Thus, if the coding style for a state machine is sequential, the implementation is also sequential.

Use the `syn_state_machine` compiler directive to specify or prevent a state machine from being extracted and optimized. To override the default encoding of the FSM Compiler, use the `syn_encoding` directive.

Table 6. `syn_encoding` Directive Values

Value	Description
Sequential	Generates state machines with the fewest possible flipflops. Sequential, also called binary, state machines are useful for area-critical designs when timing is not the primary concern.
Gray	Generates state machines where only one flipflop changes during each transition. Gray-encoded state machines tend to be glitches.
One-hot	Generates state machines containing one flipflop for each state. One-hot state machines typically provide the best performance and shortest clock-to-output delays. However, one-hot implementations are usually larger than sequential implementations.
Safe	Generates extra control logic to force the state machine to the reset state if an invalid state is reached. You can use the safe value in conjunction with any of the other three values, which results in the state machine being implemented with the requested encoding scheme and the generation of the reset logic.

Example 16. Sample VHDL Code for Applying `syn_encoding` Directive

```
SIGNAL current_state : STD_LOGIC_VECTOR (7 DOWNTO 0);
ATTRIBUTE syn_encoding : STRING;
ATTRIBUTE syn_encoding OF current_state : SIGNAL IS "sequential";
```

By default, the state machine logic is optimized for speed and area, which may be potentially undesirable for critical systems. The safe value generates extra control logic to force the state machine to the reset state if an invalid state is reached.

2.9.4.1. FSM Explorer in Synplify Pro and Premier

The Synplify Pro and Premier software use the FSM Explorer to explore different encoding styles for a state machine automatically, and then implement the best encoding based on the overall design constraints. The FSM Explorer uses the FSM Compiler to identify and extract state machines from a design. However, unlike the FSM Compiler, which chooses the encoding style based on the number of states, the FSM Explorer attempts several different encoding styles before choosing a specific one. The trade-off is that the compilation requires more time to analyze the state machine, but finds an optimal encoding scheme for the state machine.

2.9.5. Optimization Attributes and Options

2.9.5.1. Retiming in Synplify Pro and Premier

The Synplify Pro and Premier software can retime a design, which can improve the timing performance of sequential circuits by moving registers (register balancing) across combinational elements. Be aware that retimed registers incur name changes. You can retime your design from **Implementation Options** or you can use the `syn_allow_retiming` attribute.

2.9.5.2. Maximum Fan-Out

When your design has critical path nets with high fan-out, use the `syn_maxfan` attribute to control the fan-out of the net. Setting this attribute for a specific net results in the replication of the driver of the net to reduce overall fan-out. The `syn_maxfan` attribute takes an integer value and applies it to inputs or registers. The `syn_maxfan` attribute cannot be used to duplicate control signals. The minimum allowed value of the attribute is 4. Using this attribute might result in increased logic resource utilization, thus straining routing resources, which can lead to long compilation times and difficult fitting.

If you must duplicate an output register or an output enable register, you can create a register for each output pin by using the `syn_useioff` attribute.

2.9.5.3. Preserving Nets

During synthesis, the compiler maintains ports, registers, and instantiated components. However, some nets cannot be maintained to create an optimized circuit. Applying the `syn_keep` directive overrides the optimization of the compiler and preserves the net during synthesis. The `syn_keep` directive is a Boolean data type value and can be applied to wires (Verilog HDL) and signals (VHDL). Setting the value to **true** preserves the net through synthesis.

2.9.5.4. Register Packing

Intel devices allow register packing into I/O cells. Intel recommends allowing the Intel Quartus Prime software to make the I/O register assignments. However, you can control register packing with the `syn_useioff` attribute. The `syn_useioff` attribute is a Boolean data type value that can be applied to ports or entire modules. Setting

the value to **1** instructs the compiler to pack the register into an I/O cell. Setting the value to **0** prevents register packing in both the Synplify and Intel Quartus Prime software.

2.9.5.5. Resource Sharing

The Synplify software uses resource sharing techniques during synthesis, by default, to reduce area. Turning off the **Resource Sharing** option on the **Options** tab of the **Implementation Options** dialog box improves performance results for some designs. You can also turn off the option for a specific module with the `syn_sharing` attribute. If you turn off this option, be sure to check the results to verify improvement in timing performance. If there is no improvement, turn on **Resource Sharing**.

2.9.5.6. Preserving Hierarchy

The Synplify software performs cross-boundary optimization by default, which causes the design to flatten to allow optimization. You can use the `syn_hier` attribute to override the default compiler settings. The `syn_hier` attribute applies a string value to modules, architectures, or both. Setting the value to **hard** maintains the boundaries of a module, architecture, or both, but allows constant propagation. Setting the value to **locked** prevents all cross-boundary optimizations. Use the **locked** setting with the partition setting to create separate design blocks and multiple output netlists.

By default, the Synplify software generates a hierarchical `.vqm` file. To flatten the file, set the `syn_netlist_hierarchy` attribute to **0**.

2.9.5.7. Register Input and Output Delays

Two advanced options, `define_reg_input_delay` and `define_reg_output_delay`, can speed up paths feeding a register, or coming from a register, by a specific number of nanoseconds. The Synplify software attempts to meet the global clock frequency goals for a design as well as the individual clock frequency goals (set with the `define_clock` attribute). You can use these attributes to add a delay to paths feeding into or out of registers to further constrain critical paths. You can slow down a path that is too highly optimized by setting this attributes to a negative number.

The `define_reg_input_delay` and `define_reg_output_delay` options are useful to close timing if your design does not meet timing goals, because the routing delay after placement and routing exceeds the delay predicted by the Synplify software. Rerun synthesis using these options, specifying the actual routing delay (from place-and-route results) so that the tool can meet the required clock frequency. Synopsys recommends that for best results, do not make these assignments too aggressively. For example, you can increase the routing delay value, but do not also use the full routing delay from the last compilation.

In the SCOPE constraint window, the registers panel contains the following options:

- **Register**—Specifies the name of the register. If you have initialized a compiled design, select the name from the list.
- **Type**—Specifies whether the delay is an input or output delay.
- **Route**—Shrinks the effective period for the constrained registers by the specified value without affecting the clock period that is forward-annotated to the Intel Quartus Prime software.

Use the following Tcl command syntax to specify an input or output register delay in nanoseconds.

Example 17. Input and Output Register Delay

```
define_reg_input_delay {<register>} -route <delay in ns>
define_reg_output_delay {<register>} -route <delay in ns>
```

2.9.5.8. syn_direct_enable

This attribute controls the assignment of a clock-enable net to the dedicated enable pin of a register. With this attribute, you can direct the Synplify mapper to use a particular net as the only clock enable when the design has multiple clock enable candidates.

To use this attribute as a compiler directive to infer registers with clock enables, enter the `syn_direct_enable` directive in your source code, instead of the SCOPE spreadsheet.

The `syn_direct_enable` data type is Boolean. A value of **1** or **true** enables net assignment to the clock-enable pin. The following is the syntax for Verilog HDL:

```
object /* synthesis syn_direct_enable = 1 */ ;
```

2.9.5.9. I/O Standard

For certain Intel devices, specify the I/O standard type for an I/O pad in the design with the **I/O Standard** panel in the Synplify SCOPE window.

The Synplify SDC syntax for the `define_io_standard` constraint, in which the `delay_type` must be either `input_delay` or `output_delay`.

Example 18. define_io_standard Constraint

```
define_io_standard [-disable|-enable] {<objectName>} -delay_type \
[input_delay|output_delay] <columnTclName>{<value>} [<columnTclName>{<value>}...]
```

For details about supported I/O standards, refer to the *Synopsys FPGA Synthesis Reference Manual.*

2.9.6. Intel-Specific Attributes

You can use the `altera_chip_pin_lc`, `altera_io_powerup`, and `altera_io_opendrain` attributes with specific Intel device features, which are forward-annotated to the Intel Quartus Prime project, and are used during place-and-route.

2.9.6.1. altera_chip_pin_lc

Use the `altera_chip_pin_lc` attribute to make pin assignments. This attribute applies a string value to inputs and outputs. Use the attribute only on the ports of the top-level entity in the design. Do not use this attribute to assign pin locations from entities at lower levels of the design hierarchy.

Note: The `altera_chip_pin_lc` attribute is not supported for any MAX series device.

In the SCOPE window, set the value of the `altera_chip_pin_lc` attribute to a pin number or a list of pin numbers.

You can use VHDL code for making location assignments for supported Intel devices. Pin location assignments for these devices are written to the output `.tcl` file.

Note: The `data_out` signal is a 4-bit signal; `data_out[3]` is assigned to pin 14 and `data_out[0]` is assigned to pin 15.

Example 19. Making Location Assignments in VHDL

```
ENTITY sample (data_in : IN STD_LOGIC_VECTOR (3 DOWNTO 0);
    data_out: OUT STD_LOGIC_VECTOR (3 DOWNTO 0));
ATTRIBUTE altera_chip_pin_lc : STRING;
ATTRIBUTE altera_chip_pin_lc OF data_out : SIGNAL IS "14, 5, 16, 15";
```

2.9.6.2. altera_io_powerup

Use the `altera_io_powerup` attribute to define the power-up value of an I/O register that has no set or reset. This attribute applies a string value (**high**|**low**) to ports with I/O registers. By default, the power-up value of the I/O register is set to **low**.

2.9.6.3. altera_io_opendrain

Use the `altera_io_opendrain` attribute to specify open-drain mode I/O ports. This attribute applies a boolean data type value to outputs or bidirectional ports for devices that support open-drain mode.

2.10. Guidelines for Intel FPGA IP Cores and Architecture-Specific Features

Intel provides parameterizable IP cores, including LPMs, device-specific Intel FPGA IP cores, and IP available through the Intel FPGA IP Partners Program (AMPP^{SM}). You can use IP cores by instantiating them in your HDL code, or by inferring certain IP cores from generic HDL code.

You can instantiate an IP core in your HDL code with the IP Catalog and configure the IP core with the Parameter Editor, or instantiate the IP core using the port and parameter definition. The IP Catalog and Parameter Editor provide a graphical interface within the Intel Quartus Prime software to customize any available Intel FPGA IP core for the design.

The Synplify software also automatically recognizes certain types of HDL code, and infers the appropriate Intel FPGA IP core when an IP core provides optimal results. The Synplify software provides options to control inference of certain types of IP cores.

Related Information

- Recommended HDL Coding Styles, Design Recommendations User Guide
- About the IP Catalog Online Help

2.10.1. Instantiating Intel FPGA IP Cores with the IP Catalog

When you use the IP Catalog and Parameter Editor to set up and configure an IP core, the IP Catalog creates a VHDL or Verilog HDL wrapper file <*output file*>.v|vhd that instantiates the IP core.

The Synplify software uses the Intel Quartus Prime timing and resource estimation netlist feature to report more accurate resource utilization and timing performance estimates, and uses timing-driven optimization, instead of treating the IP core as a "black box." Including the generated IP core variation wrapper file in your Synplify project, gives the Synplify software complete information about the IP core.

Note: There is an option in the Parameter Editor to generate a netlist for resource and timing estimation. This option is not recommended for the Synplify software because the software automatically generates this information in the background without a separate netlist. If you do create a separate netlist <*output file*>_syn.v and use that file in your synthesis project, you must also include the <*output file*>.v|vhd file in your Intel Quartus Prime project.

Verify that the correct Intel Quartus Prime version is specified in the Synplify software before compiling the generated file to ensure that the software uses the correct library definitions for the IP core. The **Quartus Version** setting must match the version of the Intel Quartus Prime software used to generate the customized IP core.

In addition, ensure that the *QUARTUS_ROOTDIR* environment variable specifies the installation directory location of the correct Intel Quartus Prime version. The Synplify software uses this information to launch the Intel Quartus Prime software in the background. The environment variable setting must match the version of the Intel Quartus Prime software used to generate the customized IP core.

Related Information

Specifying the Intel Quartus Prime Software Version on page 20

2.10.1.1. Instantiating Intel FPGA IP Cores with IP Catalog Generated Verilog HDL Files

If you turn on the <*output file*>_inst.v option on the Parameter Editor, the IP Catalog generates a Verilog HDL instantiation template file for use in your Synplify design. The instantiation template file, <*output file*>_inst.v, helps to instantiate the IP core variation wrapper file, <*output file*>.v, in your top-level design. Include the IP core variation wrapper file <*output file*>.v in your Synplify project. The Synplify software includes the IP core information in the output .vqm netlist file. You do not need to include the generated IP core variation wrapper file in your Intel Quartus Prime project.

2.10.1.2. Instantiating Intel FPGA IP Cores with IP Catalog Generated VHDL Files

If you turn on the <*output file*>.cmp and <*output file*>_inst.vhd options on the parameter editor, the IP Catalog generates a VHDL component declaration file and a VHDL instantiation template file for use in your Synplify design. These files can help you instantiate the IP core variation wrapper file, <*output file*>.vhd, in your top-level design. Include the <*output file*>.vhd in your Synplify project. The Synplify software includes the IP core information in the output .vqm netlist file. You do not need to include the generated IP core variation wrapper file in your Intel Quartus Prime project.

2.10.1.3. Changing Synplify's Default Behavior for Instantiated Intel FPGA IP Cores

By default, the Synplify software automatically opens the Intel Quartus Prime software in the background to generate a resource and timing estimation netlist for IP cores.

You might want to change this behavior to reduce run times in the Synplify software, because generating the netlist files can take several minutes for large designs, or if the Synplify software cannot access your Intel Quartus Prime software installation to generate the files. Changing this behavior might speed up the compilation time in the Synplify software, but the Quality of Results (QoR) might be reduced.

The Synplify software directs the Intel Quartus Prime software to generate information in two ways:

- Some IP cores provide a "clear box" model—the Synplify software fully synthesizes this model and includes the device architecture-specific primitives in the output .vqm netlist file.
- Other IP cores provide a "gray box" model—the Synplify software reads the resource information, but the netlist does not contain all the logic functionality.

  Note: You need to turn on **Generate netlist** when using the gray box model. For more information, see the Intel Quartus Prime online help.

For these IP cores, the Synplify software uses the logic information for resource and timing estimation and optimization, and then instantiates the IP core in the output .vqm netlist file so the Intel Quartus Prime software can implement the appropriate device primitives. By default, the Synplify software uses the clear box model when available, and otherwise uses the gray box model.

Note: Generation of a timing and area estimation (gray box) netlist is available only for individual Intel FPGA IP, and not for Platform Designer systems.

  Includes more information about design flows using clear box model and gray box model.
- Generating a Netlist for 3rd Party Synthesis Tools online help

2.10.1.4. Instantiating Intellectual Property with the IP Catalog and Parameter Editor

Many Intel FPGA IP cores include a resource and timing estimation netlist that the Synplify software uses to report more accurate resource utilization and timing performance estimates, and uses timing-driven optimization rather than a black box function.

To create this netlist file, perform the following steps:

1. Select the IP core in the IP Catalog.
2. Click **Next** to open the Parameter Editor.
3. Click **Set Up Simulation**, which sets up all the EDA options.
4. Turn on the **Generate netlist** option to generate a netlist for resource and timing estimation and click **OK**.
5. Click **Generate** to generate the netlist file.

The Intel Quartus Prime software generates a file <*output file*>_syn.v. This netlist contains the gray box information for resource and timing estimation, but does not contain the actual implementation. Include this netlist file in your Synplify project. Next, include the IP core variation wrapper file <*output file*>.v|vhd in the Intel Quartus Prime project along with your Synplify .vqm output netlist.

If your IP core does not include a resource and timing estimation netlist, the Synplify software must treat the IP core as a black box.

Related Information

Including Files for Intel Quartus Prime Placement and Routing Only on page 35

2.10.1.5. Instantiating Black Box IP Cores with Generated Verilog HDL Files

Use the syn_black_box compiler directive to declare a module as a black box. The top-level design files must contain the IP port-mapping and a hollow-body module declaration. Apply the syn_black_box directive to the module declaration in the top-level file or a separate file included in the project so that the Synplify software recognizes the module is a black box. The software compiles successfully without this directive, but reports an additional warning message. Using this directive allows you to add other directives.

The example shows a top-level file that instantiates my_verilogIP.v, which is a simple customized variation generated by the IP Catalog.

Example 20. Sample Top-Level Verilog HDL Code with Black Box Instantiation of IP

```
module top (clk, count);
    input clk;
    output [7:0] count;
    my_verilogIP verilogIP_inst (.clock (clk), .q (count));
endmodule
// Module declaration
// The following attribute is added to create a
// black box for this module.
module my_verilogIP (clock, q) /* synthesis syn_black_box */;
    input clock;
    output [7:0] q;
endmodule
```

2.10.1.6. Instantiating Black Box IP Cores with Generated VHDL Files

Use the `syn_black_box` compiler directive to declare a component as a black box. The top-level design files must contain the IP core variation component declaration and port-mapping. Apply the `syn_black_box` directive to the component declaration in the top-level file. The software compiles successfully without this directive, but reports an additional warning message. Using this directive allows you to add other directives.

The example shows a top-level file that instantiates `my_vhdlIP.vhd`, which is a simplified customized variation generated by the IP Catalog.

Example 21. Sample Top-Level VHDL Code with Black Box Instantiation of IP

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY top IS
    PORT (
        clk: IN STD_LOGIC ;
        count: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
    );
END top;

ARCHITECTURE rtl OF top IS
COMPONENT my_vhdlIP
    PORT (
        clock: IN STD_LOGIC ;
        q: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
    );
end COMPONENT;
attribute syn_black_box : boolean;
attribute syn_black_box of my_vhdlIP: component is true;
BEGIN
    vhdlIP_inst : my_vhdlIP PORT MAP (
        clock => clk,
        q => count
    );
END rtl;
```

2.10.1.7. Other Synplify Software Attributes for Creating Black Boxes

Instantiating IP as a black box does not provide visibility into the IP for the synthesis tool. Thus, it does not take full advantage of the synthesis tool's timing-driven optimization. For better timing optimization, especially if the black box does not have registered inputs and outputs, add timing models to black boxes by adding the `syn_tpd`, `syn_tsu`, and `syn_tco` attributes.

Example 22. Adding Timing Models to Black Boxes in Verilog HDL

```
module ram32x4(z,d,addr,we,clk);
    /* synthesis syn_black_box syn_tcol="clk->z[3:0]=4.0"
        syn_tpd1="addr[3:0]->[3:0]=8.0"
        syn_tsu1="addr[3:0]->clk=2.0"
        syn_tsu2="we->clk=3.0" */
    output [3:0]z;
    input[3:0]d;
    input[3:0]addr;
    input we
    input clk
endmodule
```

The following additional attributes are supported by the Synplify software to communicate details about the characteristics of the black box module within the HDL code:

- `syn_resources`—Specifies the resources used in a particular black box.
- `black_box_pad_pin`—Prevents mapping to I/O cells.
- `black_box_tri_pin`—Indicates a tri-stated signal.

For more information about applying these attributes, refer to the *Synopsys FPGA Synthesis Reference Manual*.

2.10.2. Including Files for Intel Quartus Prime Placement and Routing Only

In the Synplify software, you can add files to your project that are used only during placement and routing in the Intel Quartus Prime software. This can be useful if you have gray or black boxes for Synplify synthesis that require the full design files to be compiled in the Intel Quartus Prime software.

You can also set the option in a script using the `-job_owner par` option.

The example shows how to define files for a Synplify project that includes a top-level design file, a gray box netlist file, an IP wrapper file, and an encrypted IP file. With these files, the Synplify software writes an empty instantiation of "core" in the `.vqm` file and uses the gray box netlist for resource and timing estimation. The files `core.v` and `core_enc8b10b.v` are not compiled by the Synplify software, but are copied into the place-and-route directory. The Intel Quartus Prime software compiles these files to implement the "core" IP block.

Example 23. Commands to Define Files for a Synplify Project

```
add_file -verilog -job_owner par "core_enc8b10b.v"
add_file -verilog -job_owner par "core.v"
add_file -verilog "core_gb.v"
add_file -verilog "top.v"
```

Note: Generation of a timing and area estimation (gray box) netlist is available only for individual Intel FPGA IP, and not for Platform Designer systems.

2.10.3. Inferring Intel FPGA IP Cores from HDL Code

The Synplify software uses Behavior Extraction Synthesis Technology (BEST) algorithms to infer high-level structures such as RAMs, ROMs, operators, FSMs, and DSP multiplication operations. Then, the Synplify software keeps the structures abstract for as long as possible in the synthesis process. This allows the use of technology-specific resources to implement these structures by inferring the appropriate Intel FPGA IP core when an IP core provides optimal results.

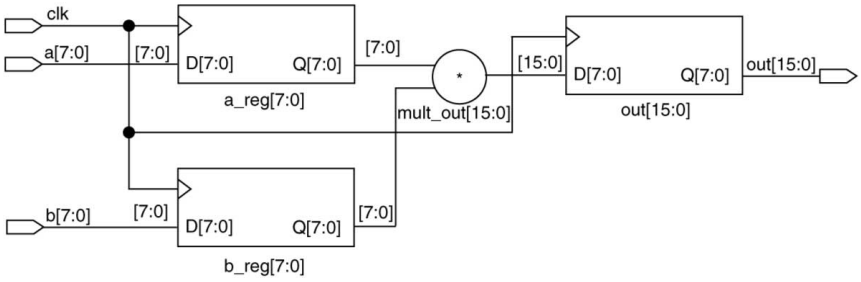
Related Information

Recommended HDL Coding Styles, Design Recommendations User Guide

2.10.3.1. Inferring Multipliers

The figure shows the HDL Analyst view of an unsigned 8 × 8 multiplier with two pipeline stages after synthesis in the Synplify software. This multiplier is converted into an ALTMULT_ADD or ALTMULT_ACCUM IP core. For devices with DSP blocks, the software might implement the function in a DSP block instead of regular logic, depending on device utilization. For some devices, the software maps directly to DSP block device primitives instead of instantiating an IP core in the **.vqm** file.

Figure 2. HDL Analyst View of LPM_MULT IP Core (Unsigned 8x8 Multiplier with Pipeline=2)



2.10.3.1.1. Resource Balancing

While mapping multipliers to DSP blocks, the Synplify software performs resource balancing for optimum performance.

Intel devices have a fixed number of DSP blocks, which includes a fixed number of embedded multipliers. If the design uses more multipliers than are available, the Synplify software automatically maps the extra multipliers to logic elements (LEs), or adaptive logic modules (ALMs).

If a design uses more multipliers than are available in the DSP blocks, the Synplify software maps the multipliers in the critical paths to DSP blocks. Next, any wide multipliers, which might or might not be in the critical paths, are mapped to DSP blocks. Smaller multipliers and multipliers that are not in the critical paths might then be implemented in the logic (LEs or ALMs). This ensures that the design fits successfully in the device.

2.10.3.1.2. Controlling the DSP Block Inference

You can implement multipliers in DSP blocks or in logic in Intel devices that contain DSP blocks. You can control this implementation through attribute settings in the Synplify software.

2.10.3.1.3. Signal Level Attribute

You can control the implementation of individual multipliers by using the `syn_multstyle` attribute as shown in the following Verilog HDL code (where *<signal_name>* is the name of the signal):

```
<signal_name> /* synthesis syn_multstyle = "logic" */;
```

The `syn_multstyle` attribute applies to wires only; it cannot be applied to registers.

Table 7. DSP Block Attribute Setting in the Synplify Software

Attribute Name	Value	Description
syn_multstyle	lpm_mult	LPM function inferred and multipliers implemented in DSP blocks.
	logic	LPM function not inferred and multipliers implemented as LEs by the Synplify software.
	block_mult	DSP IP core is inferred and multipliers are mapped directly to DSP block device primitives (for supported devices).

Example 24. Signal Attributes for Controlling DSP Block Inference in Verilog HDL Code

```
module mult(a,b,c,r,en);
    input [7:0] a,b;
    output [15:0] r;
    input [15:0] c;
    input en;
    wire [15:0] temp /* synthesis syn_multstyle="logic" */;

    assign temp = a*b;
    assign r = en ? temp : c;
endmodule
```

Example 25. Signal Attributes for Controlling DSP Block Inference in VHDL Code

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;

entity onereg is port (
    r : out std_logic_vector (15 downto 0);
    en : in std_logic;
    a : in std_logic_vector (7 downto 0);
    b : in std_logic_vector (7 downto 0);
    c : in std_logic_vector (15 downto 0);
    );
end onereg;

architecture beh of onereg is
signal temp : std_logic_vector (15 downto 0);
attribute syn_multstyle : string;
attribute syn_multstyle of temp : signal is "logic";

begin
    temp <= a * b;
    r <= temp when en='1' else c;
end beh;
```

2.10.3.2. Inferring RAM

When a RAM block is inferred from an HDL design, the Synplify software uses an Intel FPGA IP core to target the device memory architecture. For some devices, the Synplify software maps directly to memory block device primitives instead of instantiating an IP core in the `.vqm` file.

Follow these guidelines for the Synplify software to successfully infer RAM in a design:

- The address line must be at least two bits wide.
- Resets on the memory are not supported. Refer to the device family documentation for information about whether read and write ports must be synchronous.
- Some Verilog HDL statements with blocking assignments might not be mapped to RAM blocks, so avoid blocking statements when modeling RAMs in Verilog HDL.

For some device families, the `syn_ramstyle` attribute specifies the implementation to use for an inferred RAM. You can apply the `syn_ramstyle` attribute globally to a module or a RAM instance, to specify `registers` or `block_ram` values. To turn off RAM inference, set the attribute value to `registers`.

When inferring RAM for some Intel device families, the Synplify software generates additional bypass logic. This logic is generated to resolve a half-cycle read/write behavior difference between the RTL and post-synthesis simulations. The RTL simulation shows the memory being updated on the positive edge of the clock; the post-synthesis simulation shows the memory being updated on the negative edge of the clock. To eliminate bypass logic, the output of the RAM must be registered. By adding this register, the output of the RAM is seen after a full clock cycle, by which time the update has occurred, thus eliminating the need for bypass logic.

For devices with TriMatrix memory blocks, disable the creation of glue logic by setting the `syn_ramstyle` value to `no_rw_check`. Set `syn_ramstyle` to `no_rw_check` to disable the creation of glue logic in dual-port mode.

Example 26. VHDL Code for Inferred Dual-Port RAM

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_signed.all;

ENTITY dualport_ram IS
PORT ( data_out: OUT STD_LOGIC_VECTOR (7 DOWNTO 0);
    data_in: IN STD_LOGIC_VECTOR (7 DOWNTO 0)
    wr_addr, rd_addr: IN STD_LOGIC_VECTOR (6 DOWNTO 0);
    we: IN STD_LOGIC);
    clk: IN STD_LOGIC);
END dualport_ram;

ARCHITECTURE ram_infer OF dualport_ram IS
TYPE Mem_Type IS ARRAY (127 DOWNTO 0) OF STD_LOGIC_VECOR (7 DOWNTO 0);
SIGNAL mem; Mem_Type;
SIGNAL addr_reg: STD_LOGIC_VECTOR (6 DOWNTO 0);

BEGIN
    data_out <= mem (CONV_INTEGER(rd_addr));
    PROCESS (clk, we, data_in) BEGIN
        IF (clk='1' AND clk'EVENT) THEN
            IF (we='1') THEN
                mem(CONV_INTEGER(wr_addr)) <= data_in;
            END IF;
        END IF;
    END PROCESS;
END ram_infer;
```

Example 27. VHDL Code for Inferred Dual-Port RAM Preventing Bypass Logic

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_signed.all;

ENTITY dualport_ram IS
PORT ( data_out: OUT STD_LOGIC_VECTOR (7 DOWNTO 0);
```

```
    data_in : IN STD_LOGIC_VECTOR (7 DOWNTO 0);
    wr_addr, rd_addr : IN STD_LOGIC_VECTOR (6 DOWNTO 0);
    we : IN STD_LOGIC;
    clk : IN STD_LOGIC);
END dualport_ram;

ARCHITECTURE ram_infer OF dualport_ram IS
TYPE Mem_Type IS ARRAY (127 DOWNTO 0) OF STD_LOGIC_VECTOR (7 DOWNTO 0);
SIGNAL mem : Mem_Type;
SIGNAL addr_reg : STD_LOGIC_VECTOR (6 DOWNTO 0);
SIGNAL tmp_out : STD_LOGIC_VECTOR (7 DOWNTO 0); --output register

BEGIN
    tmp_out <= mem (CONV_INTEGER (rd_addr));
    PROCESS (clk, we, data_in) BEGIN
        IF (clk='1' AND clk'EVENT) THEN
            IF (we='1') THEN
                mem(CONV_INTEGER(wr_addr)) <= data_in;
            END IF;
            data_out <= tmp_out; --registers output preventing
                                 -- bypass logic generation
        END IF;
    END PROCESS;
END ram_infer;
```

2.10.3.3. RAM Initialization

Use the Verilog HDL `$readmemb` or `$readmemh` system tasks in your HDL code to initialize RAM memories. The Synplify compiler forward-annotates the initialization values in the `.srs` (technology-independent RTL netlist) file and the mapper generates the corresponding hexadecimal memory initialization (`.hex`) file. One `.hex` file is created for each of the `altsyncram` IP cores that are inferred in the design. The `.hex` file is associated with the `altsyncram` instance in the `.vqm` file using the `init_file` attribute.

The examples show how RAM can be initialized through HDL code, and how the corresponding `.hex` file is generated using Verilog HDL.

Example 28. Using $readmemb System Task to Initialize an Inferred RAM in Verilog HDL Code

```
initial
begin
    $readmemb("mem.ini", mem);
end
always @(posedge clk)
begin
    raddr_reg <= raddr;
    if(we)
        mem[waddr] <= data;
end
```

Example 29. Sample of .vqm Instance Containing Memory Initialization File

```
altsyncram mem_hex( .wren_a(we),.wren_b(GND),...);

defparam mem_hex.lpm_type = "altsyncram";
defparam mem_hex.operation_mode = "Dual_Port";
...
defparam mem_hex.init_file = "mem_hex.hex";
```

2.10.3.4. Inferring ROM

When a ROM block is inferred from an HDL design, the Synplify software uses an Intel FPGA IP core to target the device memory architecture. For some devices, the Synplify software maps directly to memory block device atoms instead of instantiating an IP core in the `.vqm` file.

Follow these guidelines for the Synplify software to successfully infer ROM in a design:

- The address line must be at least two bits wide.
- The ROM must be at least half full.
- A CASE or IF statement must make 16 or more assignments using constant values of the same width.

2.10.3.5. Inferring Shift Registers

The Synplify software infers shift registers for sequential shift components so that they can be placed in dedicated memory blocks in supported device architectures using the ALTSHIFT_TAPS IP core.

If necessary, set the implementation style with the `syn_srlstyle` attribute. If you do not want the components automatically mapped to shift registers, set the value to `registers`. You can set the value globally, or on individual modules or registers.

For some designs, turning off shift register inference improves the design performance.

2.11. Synopsys Synplify* Support Revision History

Document Version	Intel Quartus Prime Version	Changes
2022.03.28	18.1	Revised linking to documentation archives.
2018.09.24	18.1	Removed reference to obsolete .edf file from "Design Flow" diagram.
2018.05.07	18.0	Corrected trademark symbols on tool names.
2016.10.31	16.1	• Implemented Intel rebranding.

2.12. Intel Quartus Prime Pro Edition User Guide: Third-Party Synthesis Archives

For the latest and previous versions of this user guide, refer to Intel Quartus Prime Pro Edition User Guide: Third-party Synthesis. If an IP or software version is not listed, the user guide for the previous IP or software version applies.

A. Intel Quartus Prime Pro Edition User Guides

Refer to the following user guides for comprehensive information on all phases of the Intel Quartus Prime Pro Edition FPGA design flow.

Related Information

- Intel Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Intel Quartus Prime Pro Edition software, including managing Intel Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Intel Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Intel Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Intel Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Intel Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Intel Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Intel Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Intel Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Intel Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Intel Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Intel Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Intel Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Intel Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Intel Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys* that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Intel Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys*. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Intel Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Intel Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Intel Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Intel Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Intel Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Intel Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Intel Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Intel Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Intel Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Intel Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Intel Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

Answers to Top FAQs:

Contents

1. System Debugging Tools Overview

This chapter provides a quick overview of the tools available in the Intel® Quartus® Prime system debugging suite and discusses the criteria for selecting the best tool for your debug requirements.

1.1. System Debugging Tools Portfolio

The Intel Quartus Prime software provides a portfolio of system debugging tools for real-time verification of your design.

System debugging tools provide visibility by routing (or "tapping") signals in your design to debugging logic. The Compiler includes the debugging logic in your design and generates programming files that you download into the FPGA or CPLD for analysis.

Each tool in the system debugging portfolio uses a combination of available memory, logic, and routing resources to assist in the debugging process. Because different designs have different constraints and requirements, you can choose the tool that matches the specific requirements for your design, such as the number of spare pins available or the amount of logic or memory resources remaining in the physical device.

1.1.1. System Debugging Tools Comparison

Table 1. System Debugging Tools Portfolio

Tool	Description	Typical Usage
System Console and Debugging Toolkits	• Provides real-time in-system debugging capabilities using available debugging toolkits. • Allows you to read from and write to memory mapped components in a system without a processor or additional software. • Communicates with hardware modules in a design through a Tcl interpreter. • Allows you to take advantage of all the features of the Tcl scripting language. • Supports JTAG and TCP/IP connectivity.	• Perform system-level debugging. • Debug or optimize signal integrity of a board layout even before finishing the design. • Debug external memory interfaces. • Debug an Ethernet Intel FPGA IP interface in real time. • Debug a PCI Express* link at the Physical, Data Link, and Transaction layers. • Debug and optimize high-speed serial links in your board design.
Signal Tap logic analyzer	• Uses FPGA resources. • Captures data continuously from the signals you specify while the logic analyzer is running. To capture and store only specific signal data, you specify conditions that *trigger* the start or stop of data capture. A trigger activates when the trigger conditions are met, stopping analysis and displaying the data	You have spare on-chip memory and you want functional verification of a design running in hardware.

continued...

Tool	Description	Typical Usage
Signal Probe	Incrementally routes internal signals to I/O pins while preserving results from the last place-and-routed design.	You have spare I/O pins and you want to check the operation of a small set of control pins using either an external logic analyzer or an oscilloscope.
Logic Analyzer Interface (LAI)	• Multiplexes a larger set of signals to a smaller number of spare I/O pins. • Allows you to select which signals switch onto the I/O pins over a JTAG connection.	You have limited on-chip memory and a large set of internal data buses to verify using an external logic analyzer. Logic analyzer vendors, such as Tektronics* and Agilent*, provide integration with the tool to improve usability.
In-System Sources and Probes	Provides an easy way to drive and sample logic values to and from internal nodes using the JTAG interface. Provides real-time slow sampling capability.	You want to prototype the FPGA design using a front panel with virtual buttons.
In-System Memory Content Editor	Displays and allows you to edit on-chip memory.	You want to view and edit the contents of on-chip memory that is not connected to a Nios® II processor. You can also use the tool when you do not want to have a Nios II debug core in your system.
Virtual JTAG Interface	Allows you to communicate with the JTAG interface so that you can develop custom applications.	You want to communicate with custom signals in your design.

Refer to the following for more information about launching and using the available debugging toolkits:

- Launching a Toolkit in System Console on page 174
- Available System Debugging Toolkits on page 175

1.1.2. Suggested Tools for Common Debugging Requirements

Table 2. Tools for Common Debugging Requirements(1)

Requirement	Signal Probe	Logic Analyzer Interface (LAI)	Signal Tap Logic Analyzer	Description
More Data Storage	N/A	X	—	An external logic analyzer with the LAI tool allows you to store more captured data than the Signal Tap logic analyzer, because the external logic analyzer can provide access to a bigger buffer. The Signal Probe tool does not capture or store data.
Faster Debugging	X	X	—	You can use the LAI or the Signal Probe tool with external equipment, such as oscilloscopes and mixed signal oscilloscopes (MSOs). This ability provides access to timing mode, which allows you to debug combined streams of data.
Minimal Effect on Logic Design	X	X(2)	X(2)	The Signal Probe tool incrementally routes nodes to pins, with no effect on the design logic. The LAI adds minimal logic to a design, requiring fewer device resources. The Signal Tap logic analyzer has little effect on the design, because the Compiler considers the debug logic as a separate design partition.
Short Compile and Recompile Time	X	X(2)	X(2)	Signal Probe uses incremental routing to attach signals to previously reserved pins. This feature allows you to quickly recompile when you change the selection of source signals.

continued...

Requirement	Signal Probe	Logic Analyzer Interface (LAI)	Signal Tap Logic Analyzer	Description
				The Signal Tap logic analyzer and the LAI can refit their own design partitions to decrease recompilation time.
Sophisticated Triggering Capability	N/A	N/A	X	The triggering capabilities of the Signal Tap logic analyzer are comparable to commercial logic analyzers.
Low I/O Usage	—	—	X	The Signal Tap logic analyzer does not require additional output pins. Both the LAI and Signal Probe require I/O pin assignments.
Fast Data Acquisition	N/A	—	X	The Signal Tap logic analyzer can acquire data at speeds of over 200 MHz. Signal integrity issues limit acquisition speed for external logic analyzers that use the LAI.
No JTAG Connection Required	X	—	—	Signal Probe does not require a host for debugging purposes. The Signal Tap logic analyzer and the LAI require an active JTAG connection to a host running the Intel Quartus Prime software.
No External Equipment Required	—	—	X	The Signal Tap logic analyzer only requires a JTAG connection from a host running the Intel Quartus Prime software or the stand-alone Signal Tap logic analyzer. Signal Probe and the LAI require the use of external debugging equipment, such as multimeters, oscilloscopes, or logic analyzers.

Notes to Table:
1. • X indicates the recommended tools for the feature.
   • — indicates that while the tool is available for that feature, that tool might not give the best results.
   • N/A indicates that the feature is not applicable for the selected tool.

1.1.3. Debugging Ecosystem

The Intel Quartus Prime software allows you to use the debugging tools in tandem to exercise and analyze the logic under test and maximize closure.

A very important distinction in the system debugging tools is how they interact with the design. All debugging tools in the Intel Quartus Prime software allow you to read the information from the design node, but only a subset allow you to input data at runtime:

Table 3. Classification of System Debugging Tools

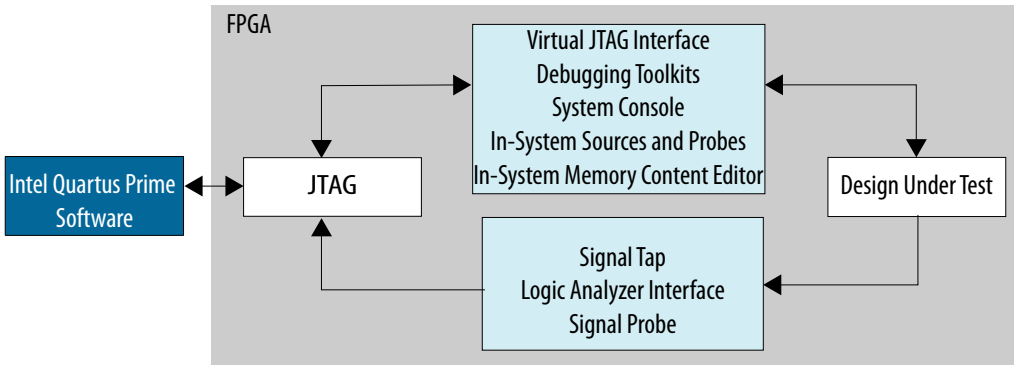
Debugging Tool	Read Data from Design	Input Values into the Design	Comments
Signal Tap logic analyzer,	Yes	No	General purpose troubleshooting tools optimized for probing signals in a register transfer level (RTL) netlist
Logic Analyzer Interface			
Signal Probe			
In-System Sources and Probes	Yes	Yes	These tools allow to:
Virtual JTAG Interface			

continued...

Debugging Tool	Read Data from Design	Input Values into the Design	Comments
System Console			• Read data from breakpoints that you define • Input values into your design during runtime
Debugging Toolkits			
In-System Memory Content Editor			

Taken together, the set of on-chip debugging tools form a debugging ecosystem. The set of tools can generate a stimulus to and solicit a response from the logic under test, providing a complete solution.

Figure 1. Debugging Ecosystem at Runtime



1.2. Tools for Monitoring RTL Nodes

The Signal Tap logic analyzer, Signal Probe, and LAI tools are useful for probing and debugging RTL signals at system speed. These general-purpose analysis tools enable you to tap and analyze any routable node from the FPGA.

- In cases when the design has spare logic and memory resources, the Signal Tap logic analyzer can provide fast functional verification of the design running on actual hardware.
- Conversely, if logic and memory resources are tight and you require the large sample depths associated with external logic analyzers, both the LAI and the Signal Probe tools simplify monitoring internal design signals using external equipment.

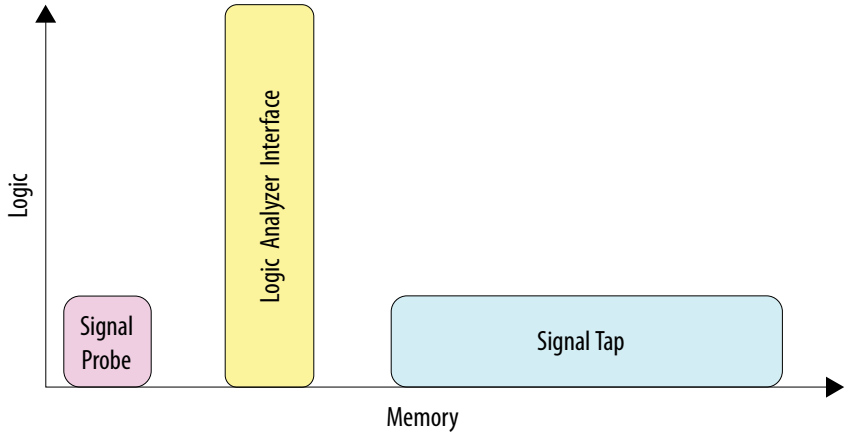
- Design Debugging with the Signal Tap Logic Analyzer on page 29
- In-System Debugging Using External Logic Analyzers on page 129

1.2.1. Resource Usage

The most important selection criteria for these three tools are the remaining resources on the device after implementing the design and the number of spare pins.

Evaluate debugging options early on in the design planning process to ensure that you support the appropriate options in the board, Intel Quartus Prime project, and design. Planning early can reduce debugging time, and eliminates last minute changes to accommodate debug methodologies.

Figure 2. Resource Usage per Debugging Tool



1.2.1.1. Overhead Logic

Any debugging tool that requires a JTAG connection requires SLD infrastructure logic for communication with the JTAG interface and arbitration between instantiated debugging modules. This overhead logic uses around 200 logic elements (LEs), a small fraction of the resources available in any of the supported devices. All available debugging modules in your design share the overhead logic. Both the Signal Tap logic analyzer and the LAI use a JTAG connection.

1.2.1.1.1. For Signal Tap Logic Analyzer

The Signal Tap logic analyzer requires both logic and memory resources. The number of logic resources used depends on the number of signals tapped and the complexity of the trigger logic. However, the amount of logic resources that the Signal Tap logic analyzer uses is typically a small percentage of most designs.

A baseline configuration consisting of the SLD arbitration logic and a single node with basic triggering logic contains approximately 300 to 400 Logic Elements (LEs). Each additional node you add to the baseline configuration adds about 11 LEs. Compared with logic resources, memory resources are a more important factor to consider for your design. Memory usage can be significant and depends on how you configure your Signal Tap logic analyzer instance to capture data and the sample depth that your design requires for debugging. For the Signal Tap logic analyzer, there is the added benefit of requiring no external equipment, as all of the triggering logic and storage is on the chip.

1.2.1.1.2. For Signal Probe

The resource usage of Signal Probe is minimal. Because Signal Probe does not require a JTAG connection, logic and memory resources are not necessary. Signal Probe only requires resources to route internal signals to a debugging test point.

1.2.1.1.3. For Logic Analyzer Interface

The LAI requires a small amount of logic to implement the multiplexing function between the signals under test, in addition to the SLD infrastructure logic. Because no data samples are stored on the chip, the LAI uses no memory resources.

1.2.2. Pin Usage

1.2.2.1. For Signal Tap Logic Analyzer

Other than the JTAG test pins, the Signal Tap logic analyzer uses no additional pins. All data is buffered using on-chip memory and communicated to the Signal Tap logic analyzer GUI via the JTAG test port.

1.2.2.2. For Signal Probe

The ratio of the number of pins used to the number of signals tapped for the Signal Probe feature is one-to-one. Because this feature can consume free pins quickly, a typical application for this feature is routing control signals to spare pins for debugging.

1.2.2.3. For Logic Analyzer Interface

The LAI can map up to 256 signals to each debugging pin, depending on available routing resources. The JTAG port controls the active signals mapped to the spare I/O pins. With these characteristics, the LAI is ideal for routing data buses to a set of test pins for analysis.

1.2.3. Usability Enhancements

The Signal Tap logic analyzer, Signal Probe, and LAI tools can be added to your existing design with minimal effects. With the node finder, you can find signals to route to a debugging module without making any changes to your HDL files. Signal Probe inserts signals directly from your post-fit database. The Signal Tap logic analyzer and LAI support inserting signals from both pre-synthesis and post-fit netlists.

1.2.3.1. Incremental Routing

Signal Probe uses the incremental routing feature. The incremental routing feature runs only the Fitter stage of the compilation. This leaves your compiled design untouched, except for the newly routed node or nodes. With Signal Probe, you can save as much as 90% compile time of a full compilation.

1.2.3.2. Automation Via Scripting

As another productivity enhancement, all tools in the on-chip debugging tool set support scripting via the `quartus_stp` Tcl package. For the Signal Tap logic analyzer and the LAI, scripting enables user-defined automation for data collection while debugging in the lab. The System Console includes a full Tcl interpreter for scripting.

1.3. Stimulus-Capable Tools

The In-System Memory Content Editor, In-System Sources and Probes, and Virtual JTAG interface enable you to use the JTAG interface as a general-purpose communication port.

Though you can use all three tools to achieve the same results, there are some considerations that make one tool easier to use in certain applications:

- The In-System Sources and Probes is ideal for toggling control signals.
- The In-System Memory Content Editor is useful for inputting large sets of test data.
- Finally, the Virtual JTAG interface is well suited for advanced users who want to develop custom JTAG solutions.

System Console provides system-level debugging at a transaction level, such as with Avalon®-MM slave or Avalon-ST interfaces. You can communicate to a chip through JTAG and TCP/IP protocols. System Console uses a Tcl interpreter to communicate with hardware modules that you instantiate into your design.

1.3.1. In-System Sources and Probes

In-System Sources and Probes allow you to read and write to a design by accessing JTAG resources.

You instantiate an Intel FPGA IP into your HDL code. This Intel FPGA IP core contains source ports and probe ports that you connect to signals in your design, and abstracts the JTAG interface's transaction details.

In addition, In-System Sources and Probes provide a GUI that displays source and probe ports by instance, and allows you to read from probe ports and drive to source ports. These features make this tool ideal for toggling a set of control signals during the debugging process.

Related Information

Design Debugging Using In-System Sources and Probes on page 145

1.3.1.1. Push Button Functionality

During the development phase of a project, you can debug your design using the In-System Sources and Probes GUI instead of push buttons and LEDs. Furthermore, In-System Sources and Probes supports a set of scripting commands for reading and writing using the Signal Tap logic analyzer. You can also build your own Tk graphical interfaces using the Toolkit API. This feature is ideal for building a virtual front panel during the prototyping phase of the design.

Related Information

Signal Tap Scripting Support on page 118

1.3.2. In-System Memory Content Editor

The In-System Memory Content Editor allows you to quickly view and modify memory content either through a GUI interface or through Tcl scripting commands. The In-System Memory Content Editor works by turning single-port RAM blocks into dual-port RAM blocks. One port is connected to your clock domain and data signals, and the other port is connected to the JTAG clock and data signals for editing or viewing.

Related Information

In-System Modification of Memory and Constants on page 137

1.3.2.1. Generate Test Vectors

Because you can modify a large set of data easily, a useful application for the In-System Memory Content Editor is to generate test vectors for your design. For example, you can instantiate a free memory block, connect the output ports to the logic under test (using the same clock as your logic under test on the system side), and create the glue logic for the address generation and control of the memory. At runtime, you can modify the contents of the memory using either a script or the In-System Memory Content Editor GUI and perform a burst transaction of the data contents in the modified RAM block synchronous to the logic being tested.

1.3.3. System Console

System Console is a framework that you can launch from the Intel Quartus Prime software to start services for performing various debugging tasks. System Console provides you with Tcl scripts and a GUI to access the Platform Designer system integration tool to perform low-level hardware debugging of your design, as well as identify a module by its path, and open and close a connection to a Platform Designer module. You can access your design at a system level for purposes of loading, unloading, and transferring designs to multiple devices. Also, System Console supports the Tk toolkit for building graphical interfaces.

Related Information

Analyzing and Debugging Designs with System Console on page 159

1.3.3.1. Test Signal Integrity

System Console also allows you to access commands that allow you to control how you generate test patterns, as well as verify the accuracy of data generated by test patterns. You can use JTAG debug commands in System Console to verify the functionality and signal integrity of your JTAG chain. You can test clock and reset signals.

1.3.3.2. Board Bring-Up and Verification

You can use System Console to access programmable logic devices on your development board, perform board bring-up, and perform verification. You can also access software running on a Nios II or Intel FPGA SoC processor, as well as access modules that produce or consume a stream of bytes.

1.3.3.3. Debug with Available Toolkits

System Console provides the hardware debugging infrastructure to run the debugging toolkits that you can enable by the use of debug-enabled Intel FPGA IP. The debugging toolkits can help you to debug external memory interfaces, Ethernet interfaces, PCI Express links, Serial Lite IV links, and high-speed serial links by providing real-time monitoring and debugging of the design running on a board.

Refer to the following for more information about launching and using the available debugging toolkits:

- Launching a Toolkit in System Console on page 174
- Available System Debugging Toolkits on page 175

1.4. Virtual JTAG Interface Intel FPGA IP

The Virtual JTAG Interface Intel FPGA IP provides the finest level of granularity for manipulating the JTAG resource. This Intel FPGA IP allows you to build your own JTAG scan chain by exposing all of the JTAG control signals and configuring your JTAG Instruction Registers (IRs) and JTAG Data Registers (DRs). During runtime, you control the IR/DR chain through a Tcl API, or with System Console. This feature is meant for users who have a thorough understanding of the JTAG interface and want precise control over the number and type of resources used.

Related Information

- Virtual JTAG Interface (VJI) Intel FPGA IP
  In *Intel Quartus Prime Help*

1.5. System-Level Debug Fabric

During compilation, the Intel Quartus Prime generates the JTAG Hub to allow multiple instances of debugging tools in a design.

Most Intel FPGA on-chip debugging tools use the JTAG port to control and read-back data from debugging logic and signals under test. The JTAG Hub manages the sharing of JTAG resources.

Note: For System Console, you explicitly insert debug IP cores into the design to enable debugging.

The JTAG Hub appears in the project's design hierarchy as a partition named `auto_fab_<number>`.

1.6. SLD JTAG Bridge

The SLD JTAG Bridge extends the debug fabric across partitions, allowing a higher-level partition (static region or root partition) to access debug signals in a lower-level partition (partial reconfiguration region or core partition).

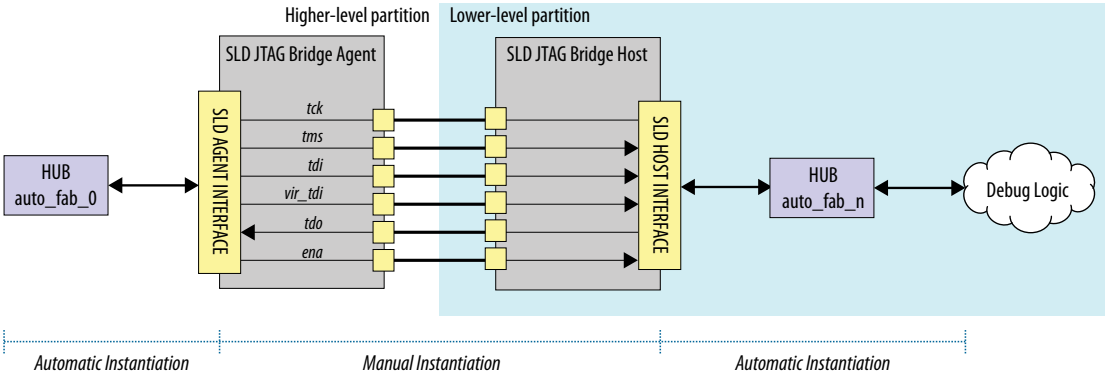
This bridge consists of two IP components:

- **SLD JTAG Bridge Agent Intel FPGA IP**—Resides in the higher-level partition.

  Extends the JTAG debug fabric from a higher-level partition to a lower-lever partition containing the SLD JTAG Bridge Host IP. You instantiate the SLD JTAG Bridge Agent IP in the higher-level partition.
- **SLD JTAG Bridge Host Intel FPGA IP**—resides in the lower-level partition. Connects to the PR JTAG hub on one end, and to the SLD JTAG Bridge Agent on the higher-level partition.

  Connects the JTAG debug fabric in a lower-level to a higher-level partition containing the SLD JTAG Bridge Agent IP. You instantiate the SLD JTAG Bridge Host IP in the lower-level partition.

Figure 3. Signals in a SLD JTAG Bridge



For each PR region or reserved core partition you debug, you must instantiate one SLD JTAG Bridge Agent in the higher-level partition and one SLD JTAG Bridge Host in the lower-level partition.

1.6.1. SLD JTAG Bridge Index

The SLD JTAG Bridge Index uniquely identifies instances of the SLD JTAG Bridge present in a design. You can find information regarding the Bridge Index in the synthesis report.

The Intel Quartus Prime software supports multiple instances of the SLD JTAG Bridge in designs. The Compiler assigns an index number to distinguish each instance. The bridge index for the root partition is always None.

When configuring the Signal Tap logic analyzer for the root partition, set the **Bridge Index** value to **None** in the JTAG Chain Configuration window.

Figure 4. JTAG Chain Configuration Bridge Index

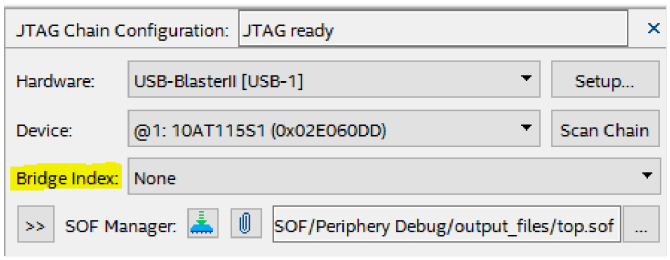


Figure 5. Design with Multiple SLD JTAG Bridges

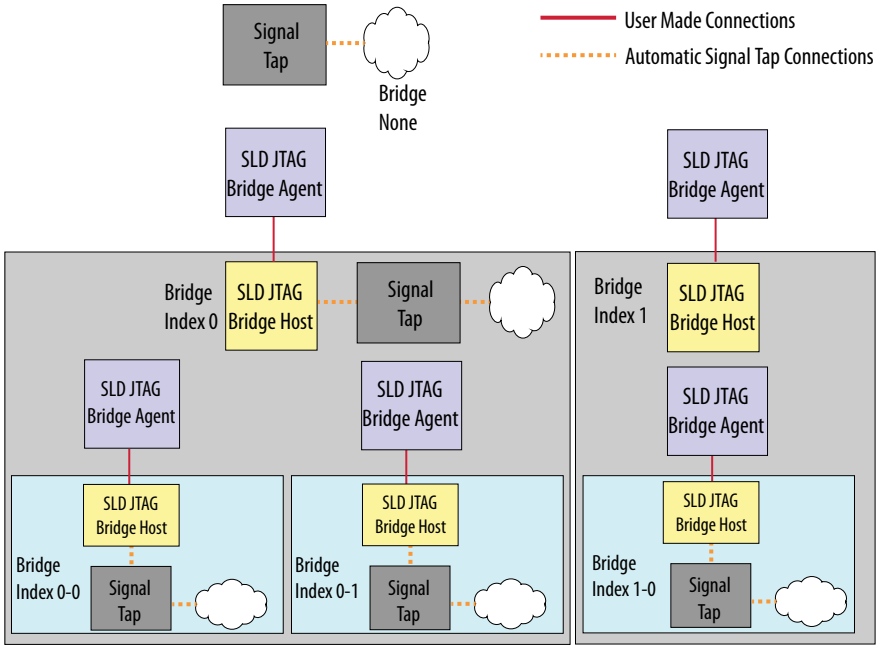
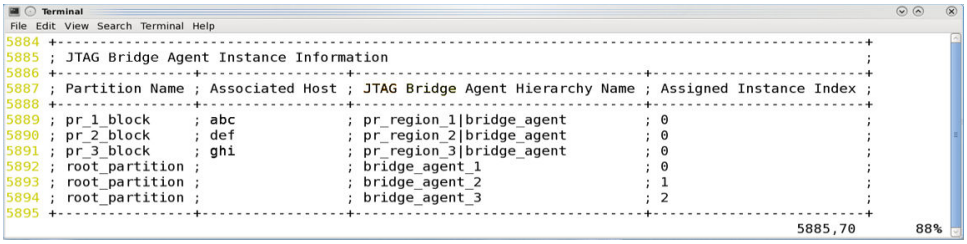


Bridge Index Information in the Compilation Report

Following design synthesis, the Compilation Report lists the index numbers for the SLD JTAG Bridge Agents in the design. Open the **Synthesis ➤ In-System Debugging ➤ JTAG Bridge Instance Agent Information** report for details about how the bridge indexes are enumerated. The reports shows the hierarchy path and the associated index.

In the synthesis report (`<base revision>.syn.rpt`), this information appears in the table **JTAG Bridge Agent Instance Information**.

Figure 6. JTAG Bridge Agent Instance Information

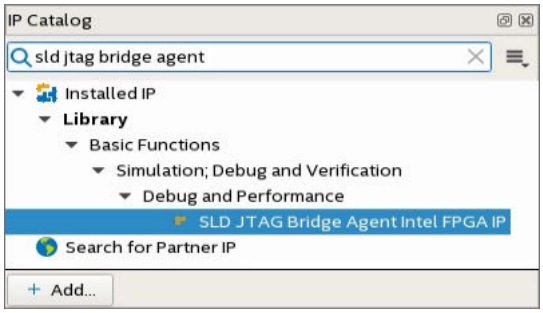


1.6.2. Instantiating the SLD JTAG Bridge Agent

To generate and instantiate the SLD JTAG Bridge Agent Intel FPGA IP:

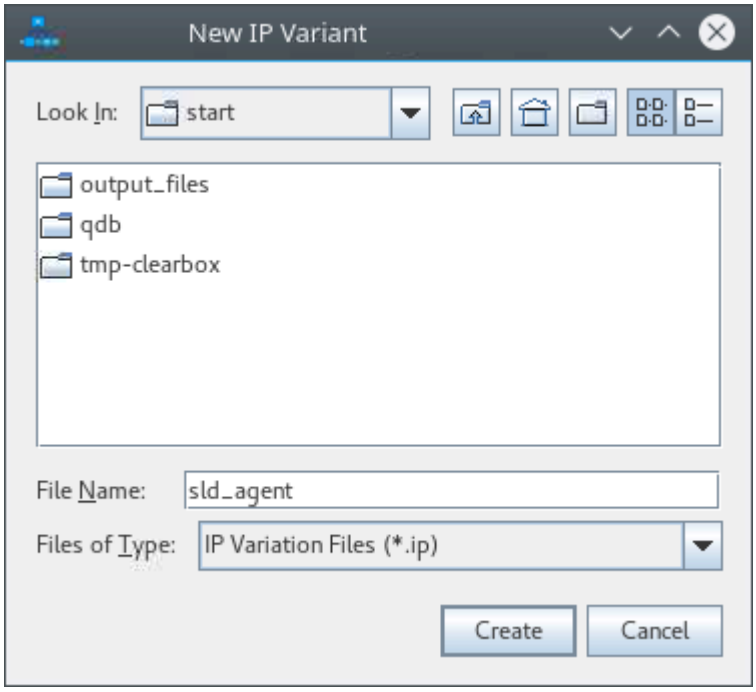
1. On the IP Catalog (**Tools ➤ IP Catalog**), type `SLD JTAG Bridge Agent`.

Figure 7. Find in IP Catalog



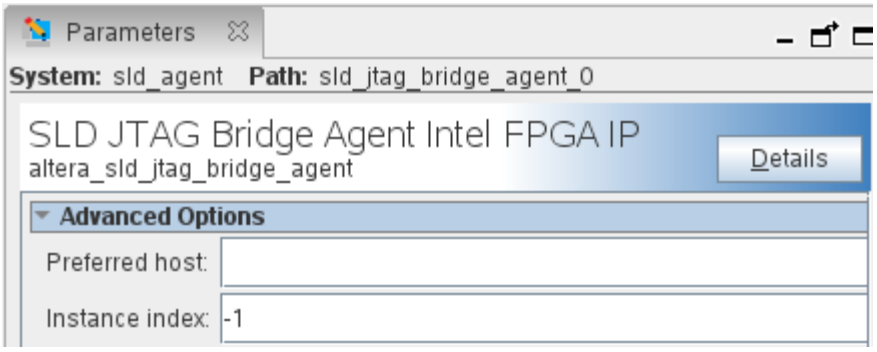
2. Double click **SLD JTAG Bridge Agent Intel FPGA IP**.
3. In the **Create IP Variant** dialog box, type a file name, and then click **Create**.

Figure 8. Create IP Variant Dialog Box



The **IP Parameter Editor Pro** window shows the IP parameters. In most cases, you do not need to change the default values.

Figure 9. SLD JTAG Bridge Agent Intel FPGA IP Parameters



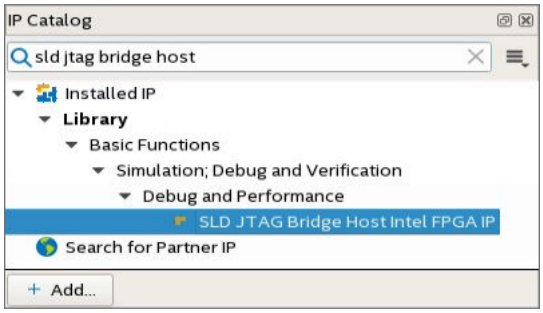
4. Click **Generate HDL**.
5. When the generation completes successfully, click **Close**.
6. If you want an instantiation template, click **Generate ➤ Show Instantiation Template** in the **IP Parameter Editor Pro**.

1.6.3. Instantiating the SLD JTAG Bridge Host

To generate and instantiate the SLD JTAG Bridge Host Intel FPGA IP:

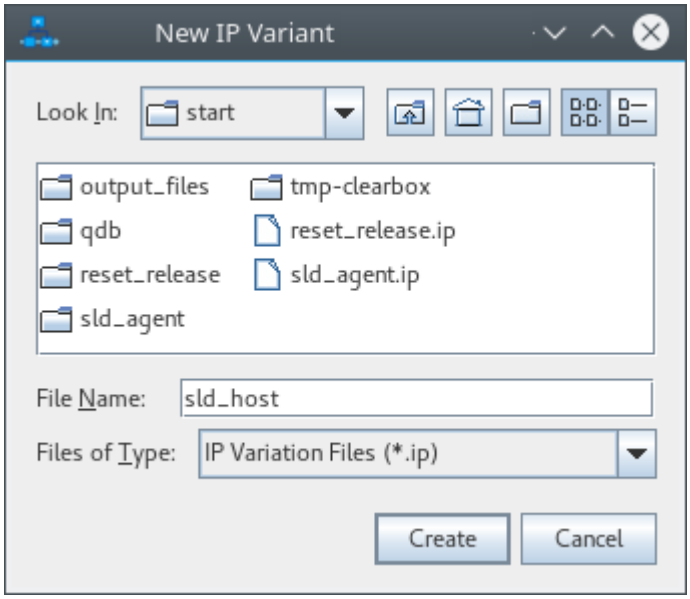
1. On the IP Catalog (**Tools ➤ IP Catalog**), type `SLD JTAG Bridge Host`.

Figure 10. Find in IP Catalog



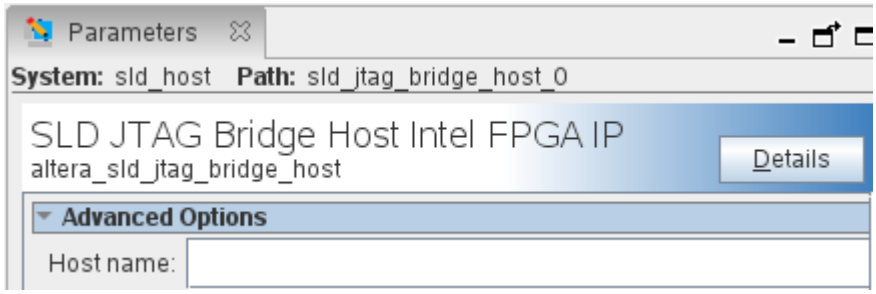
2. Double click **SLD JTAG Bridge Host Intel FPGA IP**.
3. In the **Create IP Variant** dialog box, type a file name, and then click **Create**.

Figure 11. Create IP Variant Dialog Box



The **IP Parameter Editor Pro** window shows the IP parameters. In most cases, you do not need to change the default values.

Figure 12. SLD JTAG Bridge Host Intel FPGA IP Parameters



4. Click **Generate HDL**.
5. When the generation completes successfully, click **Close**.
6. If you want an instantiation template, click **Generate ➤ Show Instantiation Template** in the **IP Parameter Editor Pro**.

1.7. Partial Reconfiguration Design Debugging

The following Intel FPGA IP cores support system-level debugging in the static region of a PR design:

- In-System Memory Content Editor
- In-System Sources and Probes Editor
- Virtual JTAG
- Nios II JTAG Debug Module
- Signal Tap Logic Analyzer

In addition, the Signal Tap logic analyzer allows you to debug the static or partial reconfiguration (PR) regions of the design. If you only want to debug the static region, you can use the In-System Sources and Probes Editor, In-System Memory Content Editor, or System Console with a JTAG Avalon bridge.

Related Information

Debugging Partial Reconfiguration Designs with Signal Tap on page 103

1.7.1. Debug Fabric for Partial Reconfiguration Designs

You must prepare the design for PR debug during the early planning stage, to ensure that you can debug the static as well as PR region.

On designs with Partial Reconfiguration, the Compiler generates centralized debug managers—or hubs—for each region (static and PR) that contains system level debug agents. Each hub handles the debug agents in its partition. In the design hierarchy, the hub corresponding to the static region is `auto_fab_0`.

To connect the hubs on parent and child partitions, you must instantiate one SLD JTAG Bridge for each PR region that you want to debug.

Related Information

- PR Design Setup for Signal Tap Debug on page 104
- Debugging Partial Reconfiguration Designs with Signal Tap on page 103

1.7.1.1. Generation of PR Debug Infrastructure

During compilation, the synthesis engine performs the following functions:

- Generates a main JTAG hub in the static region.
- If the static region contains Signal Tap instances, connects those instances to the main JTAG hub.
- Detects bridge agent and bridge host instances.
- Connects the SLD JTAG bridge agent instances to the main JTAG hub.
- For each bridge host instance in a PR region that contains a Signal Tap instance:
  - Generates a PR JTAG hub in the PR region.
  - Connects all Signal Tap instances in the PR region to the PR JTAG hub.
  - Detects instance of the SLD JTAG bridge host.
  - Connects the PR JTAG hub to the JTAG bridge host.

1.8. Preserving Signals for Debugging

The Intel Quartus Prime Pro Edition software allows you to mark and preserve specific signals through the compilation process, which enables visibility of any node within the available system debugging tools.

To ensure that specific nodes in your RTL are available for debugging after the Compiler's synthesis and place-and-route stages, you can apply the `preserve_for_debug` attribute to the signals of interest in your RTL, and also apply the **Enable preserve for debug assignments** project-level `.qsf` assignment.

This section refers to the following terms to explain use of the preserve for debug feature:

Table 4. Debug Signal Preservation Terminology

Term	Description
node	A signal name present in your design RTL and possibly in the compilation netlist for the current project. Typically, the node name refers to the output of a logical unit, such as gate, register, LUT, embedded memory, DSP, or others. The Intel Quartus Prime GUI can display this node name in various locations, such as the Node Finder, when debugging the signals in your design. You can search for this node name to apply constraints and use in debugging operations.
hpath	The Intel Quartus Prime-style hierarchical path, with instance names separated by "|", for example:`foo|boo|node`

1.8.1. Preserve for Debug Overview

The preserve for debug feature allows you to designate nodes in your design for full debugging visibility. In this context, full visibility means that you can ensure that the node name remains in the post-fit netlist generated by Place and Route, with the same name and functionality the design files define.

After you apply preserve for debug, you can easily access these nodes through the Node Finder filters available in the Intel Quartus Prime debugging tools.

Typically, you lose some visibility into the design when you debug using a post-fit netlist. This loss occurs because in the post-fit netlist, the design is already mapped to the device architecture, optimized, and retimed. The Place and Route stage often changes or removes the original signal names. Furthermore, there can be slight changes in the behavior in the post-fit netlist because of inverter push back, or because the visible signal shows only partial behavior due to logic duplication.

Preserve for Debug Use Cases

Preserve for debug is primarily for debugging purposes, and is particularly useful in the Signal Tap debugging flow, as Preserving Signals for Monitoring and Debugging on page 40 describes.

In addition, use of preserve for debug can also be helpful in any of the available system debugging tools, or within any instrumentation logic that you use in your design.

Preserve for Debug Hardware Implementation

Applying the preserve for debug feature has the following effects on hardware implementation:

- Prevents the Compiler from optimizing the specified node.
- Results in LCELL module instantiation for the specified node, impacting the overall timing on the node path.

Application of preserve for debug is the hardware equivalent of using all of the following HDL pragmas on the specified node:

Table 5. Combined Attributes

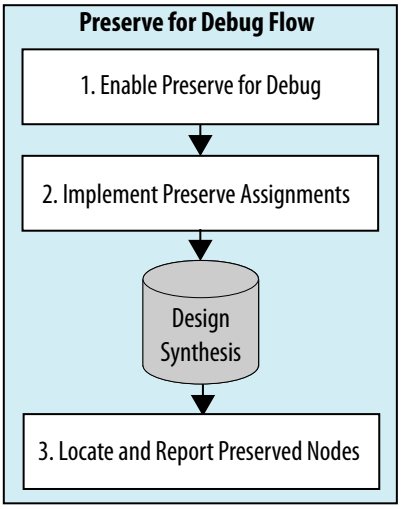
HDL Pragma	Compiler Setting	Description
`preserve`	PRESERVE_REGISTER	Prevents the Compiler from optimizing away or retiming a register.
`keep`	HDL only	Prevents the Compiler from minimizing or removing a particular signal net during combinational logic optimization.
`noprune`	HDL only	Prevents the Compiler from removing or optimizing a fan-out free register.
`dont_merge`	HDL only	Prevents the Compiler from merging a register with a duplicate register.
`dont_replicate`	HDL only	Prevents the Compiler from merging a register with a duplicate register.

1.8.2. Marking Signals for Debug

You can mark (designate) a node for preservation by use of an RTL pragma in your design file, or by specifying an assignment in the project revision `.qsf`.

You can enable or disable preserve for debug at the entity level or globally, so there is no need to individually disable marked signals when ready to compile a production stage design.

Figure 13. Preserve for Debug Flow



- Step 1: Enabling Preserve for Debug on page 23
- Step 2: Implement Preserve for Debug Assignments on page 24
- Step 3: Locate and Report Preserve for Debug Nodes on page 25

1.8.2.1. Step 1: Enabling Preserve for Debug

To ensure that the Compiler correctly processes the signals that you mark for preservation, and that the Intel Quartus Prime software Node Finders and filters correctly display these names, you must first turn on the **Enable preserve for debug assignments** setting in the GUI or project revision `.qsf`, as the following methods describe.

Note: The instance-level preserve for debug assignment takes precedence over the global preserve for debug assignment if the two assignments are in opposition to each other (that is, one assignment type is set to On, the other assignment type is set to Off).

Enabling Preserve for Debug In Project Settings on page 23

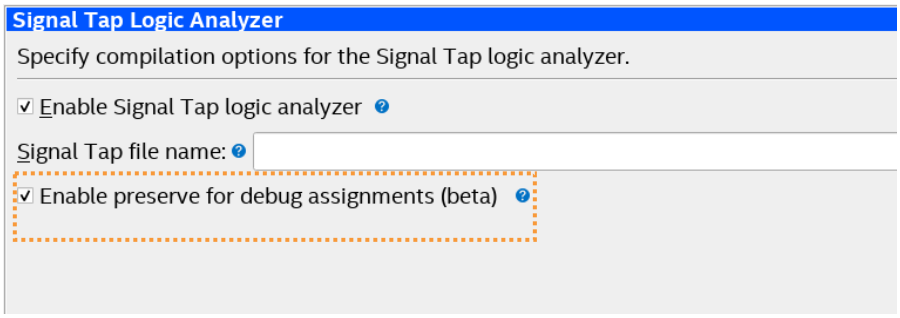
Enabling Preserve for Debug at Instance Level on page 24

1.8.2.1.1. Enabling Preserve for Debug In Project Settings

To enable preserve for debug in the project settings:

1. In the Intel Quartus Prime software, click **Assignments ➤ Settings ➤ Signal Tap Logic Analyzer**.
2. On the **Signal Tap Logic Analyzer** settings page, turn on the **Enable preserve for debug assignments** option. Preserve for debug enables project-wide.

Figure 14. Signal Tap Logic Analyzer Settings



As an alternative to the GUI setting, you can enable or disable project-wide preserve for debug by adding or modifying the following assignment in the project revision `.qsf`:

```
set_global_assignment -name PRESERVE_FOR_DEBUG_ENABLE <ON|OFF>
```

1.8.2.1.2. Enabling Preserve for Debug at Instance Level

You can enable preserve for debug in certain design blocks, and leave the feature disabled in other design blocks.

To enable the assignment at the instance level, you must specify the instance name to enable or disable for preserve for debug, as the following assignment shows:

```
set_instance_assignment -name PRESERVE_FOR_DEBUG_ENABLE ON -to \
     <instance hpath>
```

1.8.2.2. Step 2: Implement Preserve for Debug Assignments

Implement preserve for debug assignments through HDL pragmas in the design files (recommended), or by specifying assignments in the Assignment Editor or project `.qsf` file directly. The following topics provide more details:

HDL Implementation on page 24
Intel Quartus Prime Settings Implementation on page 25

1.8.2.2.1. HDL Implementation

The recommended method of preserving nodes for debug is to add HDL pragmas or attributes to the design files.

Preserve for Debug Pragma defines the preserve for debug pragma and `.qsf` assignment setting.

Table 6. Preserve for Debug Pragma

Term	Equivalent (.qsf) Setting	Description
`preserve_for_debug`	`PRESERVE_FOR_DEBUG`	Prevents the Fitter from optimizing away a register or combinational signal. The pragma also prevents any retiming, merging, and duplication optimization. This optimization prevention applies when the setting, `PRESERVE_FOR_DEBUG_ENABLE` is `ON`.

Add HDL pragmas to Verilog HDL design files in the following way:

```
(* preserve_for_debug *) reg my_reg;
```

Add HDL attributes to VHDL design files in the following way:

```
signal keep_wire : std_logic;
attribute keep: boolean;
attribute keep of keep_wire: signal is true;
```

1.8.2.2.2. Intel Quartus Prime Settings Implementation

As an alternative to HDL pragmas, you can specify the following assignment to apply the Preserve for Debug assignment through the `.qsf` settings file directly, or with Assignment Editor.

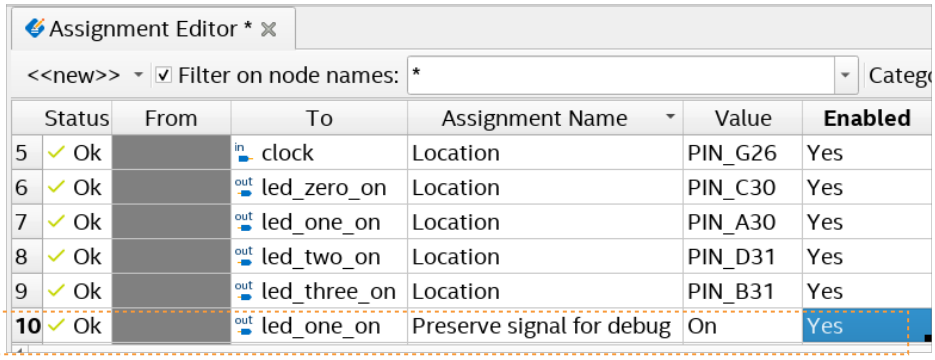
```
set_instance_assignment -name PRESERVE_FOR_DEBUG ON -to \
     <node hpath>
```

Note: This assignment supports the use of wildcards (*).

Specifying Preserve Signal for Debug in the Assignment Editor

If you prefer to specify assignments in the Intel Quartus Prime software GUI, rather than in the `.qsf` directly, you can specify the **Preserve signal for debug** assignment in Assignment Editor (Assignments menu).

Figure 15. Specifying the Preserve Signal for Debug in the Assignment Editor



1.8.2.3. Step 3: Locate and Report Preserve for Debug Nodes

After running design synthesis, you can locate preserve for debug nodes using the Node Finder in the system debugging tools. In addition, you can view data about the preserve for debug nodes in the Compilation Report. The following topics describe locating and reporting on preserve for debug nodes:

Locating Preserve for Debug Nodes on page 25

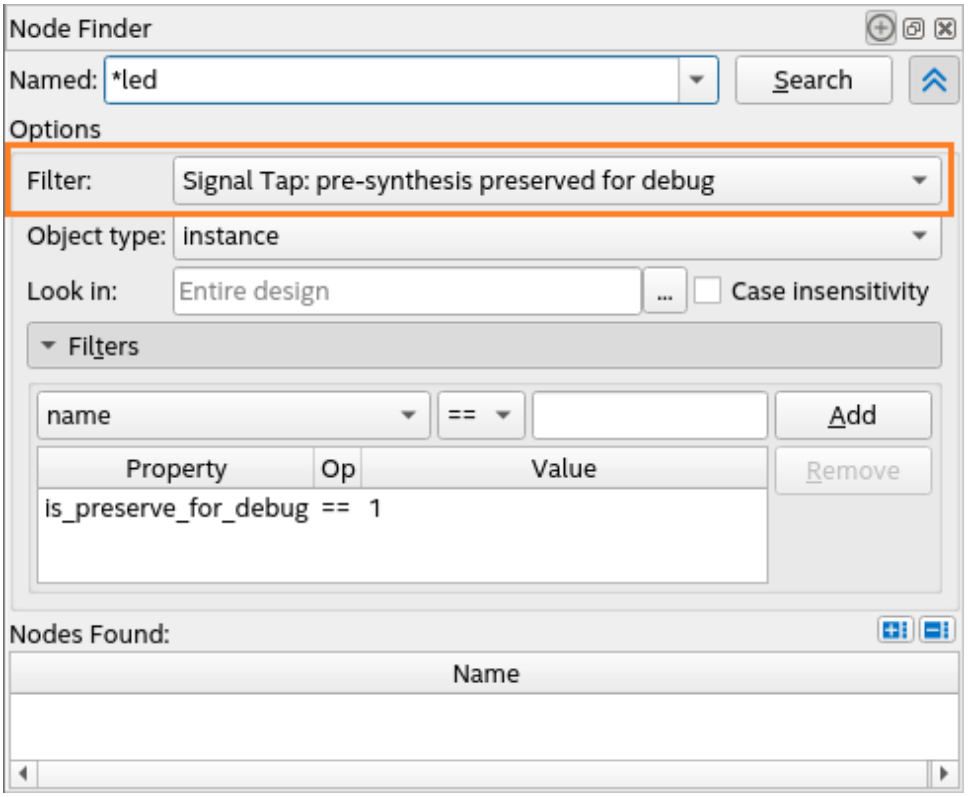
Reporting Preserve for Debug Nodes on page 26

1.8.2.3.1. Locating Preserve for Debug Nodes

The Node Finder includes the following filters that simplify the process of locating the preserve for debug nodes in your project database:

- **Signal Tap: pre-synthesis preserved for debug** filter—shows preserved nodes from the pre-synthesis netlist that generates during Analysis & Elaboration.
- **Signal Tap: post-fitting preserved for debug filter**—shows preserved nodes from the post-fit netlist.

Figure 16. Node Finder with Preserve for Debug Filter



1.8.2.3.2. Reporting Preserve for Debug Nodes

You can view data about preserve for debug nodes in the Compilation Report **Preserve for Debug** folder following Analysis & Synthesis.

The Preserve for Debug Assignments for Partition report is located in **Tools ➤ Compilation Report ➤ Synthesis ➤ Partition <name> ➤ Preserve for Debug**.

Figure 18. Preserve for Debug Assignments for Partition Report

	Name	Status
1	pc|mlb_select	enabled
2	av_addr	enabled
3	i_eth_reconfig_write	enabled
4	i_reconfig_clk	enabled
5	i_stats_snapshot	enabled
6	ninit_done	enabled
7	rd1_ready	enabled
8	pc|packet_gen_valid	enabled

1.9. System Debugging Tools Overview Revision History

The following revision history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.10.02	23.3	• Updated the Node Finder image in *Locating Preserve for Debug Nodes*.
2021.10.04	21.3	• Added new *Preserving Signals for Debugging* section. • Removed obsolete *Remote Debugging* topic. This feature is not supported in the Intel Quartus Prime Pro Edition software. • Removed obsolete *Remote Debugging* chapter 8. This feature is not supported in the Intel Quartus Prime Pro Edition software.
2020.09.28	20.3	• Revised "System Debugging Tools Comparison" to reflect replacement of Transceiver Toolkit with the available debugging toolkits. • Revised "Debugging Ecosystem" to reflect replacement of Transceiver Toolkit with the available debugging toolkits.
2019.09.30	19.3	• Clarified meaning of PR and static regions in "Partial Reconfiguration Design Debugging" topic. • Removed references to Application Notes 693.
2018.09.24	18.1	• Added figures about SLD JTAG Bridge. • Added information about block-based design.
2018.05.07	18.0	• Moved here information about debug fabric on PR designs from the *Design Debugging with the Signal Tap Logic Analyzer* chapter.
2017.05.08	17.0	• Combined Altera JTAG Interface and Required Arbitration Logic topics into a new updated topic named System-Level Debugging Infrastructure. • Added topic: Debug the Partial Reconfiguration Design with System Level Debugging Tools.
2016.10.31	16.1	• Implemented Intel rebranding.
2015.11.02	15.1	Changed instances of *Quartus II* to *Intel Quartus Prime*.
June 2014	14.0	Added information that System Console supports the Tk toolkit.
November 2013	13.1	Dita conversion. Added link to Remote Debugging over TCP/IP for Altera SoC Application Note.
June 2012	12.0	Maintenance release.

continued...

Document Version	Intel Quartus Prime Version	Changes
November 2011	10.0	Maintenance release. Changed to new document template.
December 2010	10.0	Maintenance release. Changed to new document template.
July 2010	10.0	Initial release

2. Design Debugging with the Signal Tap Logic Analyzer

2.1. Signal Tap Logic Analyzer Introduction

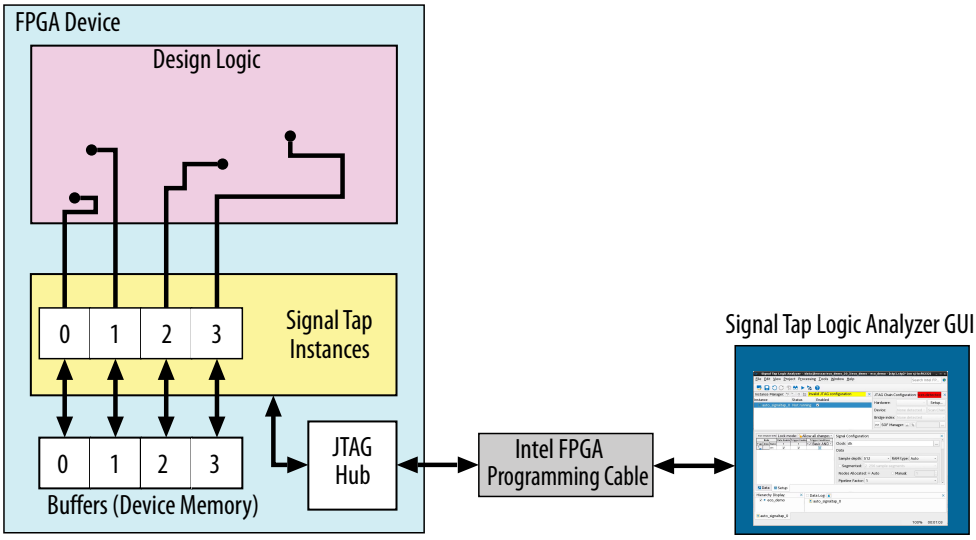
The Signal Tap logic analyzer, available in the Intel Quartus Prime software, captures and displays the real-time signal behavior in an Intel FPGA design. Use the Signal Tap logic analyzer to probe and debug the behavior of internal signals during normal device operation, without requiring extra I/O pins or external lab equipment.

By default, the Signal Tap logic analyzer captures data continuously from the signals you specify while the logic analyzer is running. To capture and store only specific signal data, you specify conditions that *trigger* the start or stop of data capture. A trigger activates when the trigger conditions are met, stopping analysis and displaying the data. You can save the captured data in device memory for later analysis, and filter data that is not relevant.

Signal Tap Logic Analyzer *Instance*

You enable the logic analyzer functionality by defining one or more instances of the Signal Tap logic analyzer in your project. You can define the properties of the Signal Tap instance in the Signal Tap logic analyzer GUI, or by HDL instantiation of the Signal Tap Logic Analyzer Intel FPGA IP. After design compilation, you configure the target device with your design (including any Signal Tap instances), which enables data capture and communication with the Signal Tap logic analyzer GUI over a JTAG connection.

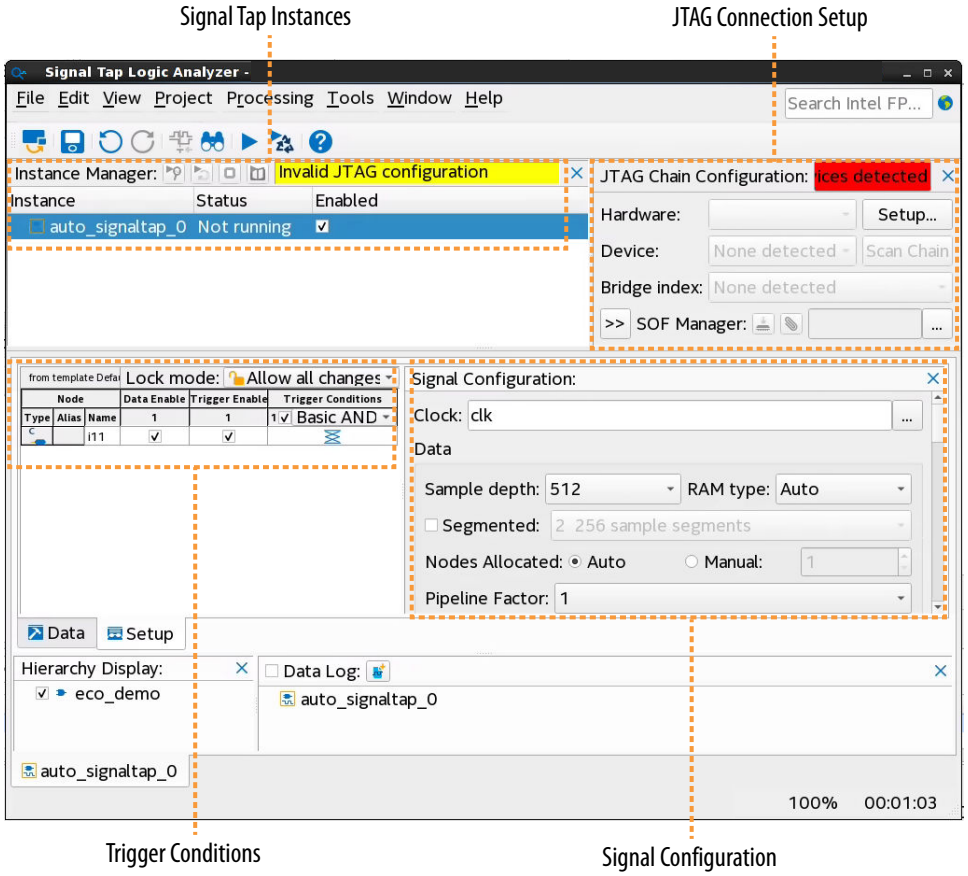
Figure 19. Signal Tap Logic Analyzer Block Diagram



Signal Tap Logic Analyzer *GUI*

The Signal Tap logic analyzer GUI helps you to rapidly define and modify Signal Tap signal configuration and JTAG connection settings, displays the captured signals during analysis, starts and stops analysis, and displays and records signal data. When you configure a Signal Tap instance in the GUI, Signal Tap preserves the instance settings in a Signal Tap Logic Analyzer file (`.stp`) for reuse.

Figure 20. Signal Tap Logic Analyzer GUI



Signal Tap Logic Analyzer and Simulator Integration

You can integrate the Signal Tap logic analyzer with your supported simulator environment. Signal Tap can readily generate a list of "simulator-aware" nodes to tap for any design hierarchy. Tapping this set of nodes then provides full visibility into the entire design hierarchy for direct observation of all internal signal states in your RTL simulator.

Signal Tap also supports automatic RTL simulation testbench creation, allowing you to export acquired Signal Tap hardware data directly into your RTL simulator and observe signals beyond those that you specify for tapping in Signal Tap. You can produce simulation events using the live data traffic to replicate in your simulator.

Signal Tap Logic Analyzer Capabilities

The Signal Tap logic analyzer supports a high number of channels, a large sample depth, fast clock speeds, and other features described in the *Key Signal Tap Logic Analyzer Capabilities* table.

Table 7. Key Signal Tap Logic Analyzer Capabilities

Capability	Benefit
Multiple logic analyzers in a single device, or in multiple devices in a single chain	Capture data from multiple clock domains and from multiple devices at the same time.
Up to 10 trigger conditions for each analyzer instance	Send complex data capture commands to the logic analyzer for greater accuracy and problem isolation.
Power-up trigger	Capture signal data for triggers that occur after device programming, but before manually starting the logic analyzer.
Custom trigger HDL object	Define a custom trigger in Verilog HDL or VHDL and tap specific instances of modules across the design hierarchy, without manual routing of all the necessary connections.
State-based triggering flow	Organize triggering conditions to precisely define data capture.
Flexible buffer acquisition modes	Precise control of data written into the acquisition buffer. Discard data samples that are not relevant to the debugging of your design.
MATLAB* integration with MEX function	Collect Signal Tap capture data into a MATLAB integer matrix.
RTL simulator integration	Easily create a set of nodes to tap for the design hierarchy, and observe all internal signal states in your RTL simulator. Automatic testbench creation allows you to inject acquired Signal Tap data directly into your RTL simulator.
Up to 4,096 channels per logic analyzer instance	Samples many signals and wide bus structures.
Up to 128K samples per instance	Captures a large sample set for each channel.
Fast clock frequencies	Synchronous sampling of data nodes using the same clock tree driving the logic under test.
Compatible with other debugging utilities	Use the Signal Tap logic analyzer in tandem with any JTAG-based on-chip debugging tool, such as an In-System Memory Content editor, to change signal values in real-time.
Floating-Point Display Format	• Single-precision floating-point format **IEEE754 Single (32-bit)**. • Double-precision floating-point format **IEEE754 Double (64-bit)**.

2.1.1. Signal Tap Hardware and Software Requirements

All editions of the Intel Quartus Prime design software include the Signal Tap logic analyzer GUI and Signal Tap Logic Analyzer Intel FPGA IP. The Signal Tap logic analyzer is also available as a stand-alone application.

During data acquisition, the memory blocks in the FPGA device store the captured data, and then transfer the data to the Signal Tap logic analyzer over a JTAG communication cable, such as Intel FPGA Ethernet Cable or Intel FPGA Download Cable.

The Signal Tap logic analyzer requires the following hardware and software to perform logic analysis:

- The Signal Tap logic analyzer included with the Intel Quartus Prime software, or the Signal Tap logic analyzer standalone software and standalone Programmer software.
- An Intel FPGA download or communications cable.
- An Intel development kit, or your own design board with a JTAG connection to the device under test.

Related Information

Running the Stand-Alone Version of Signal Tap on page 118

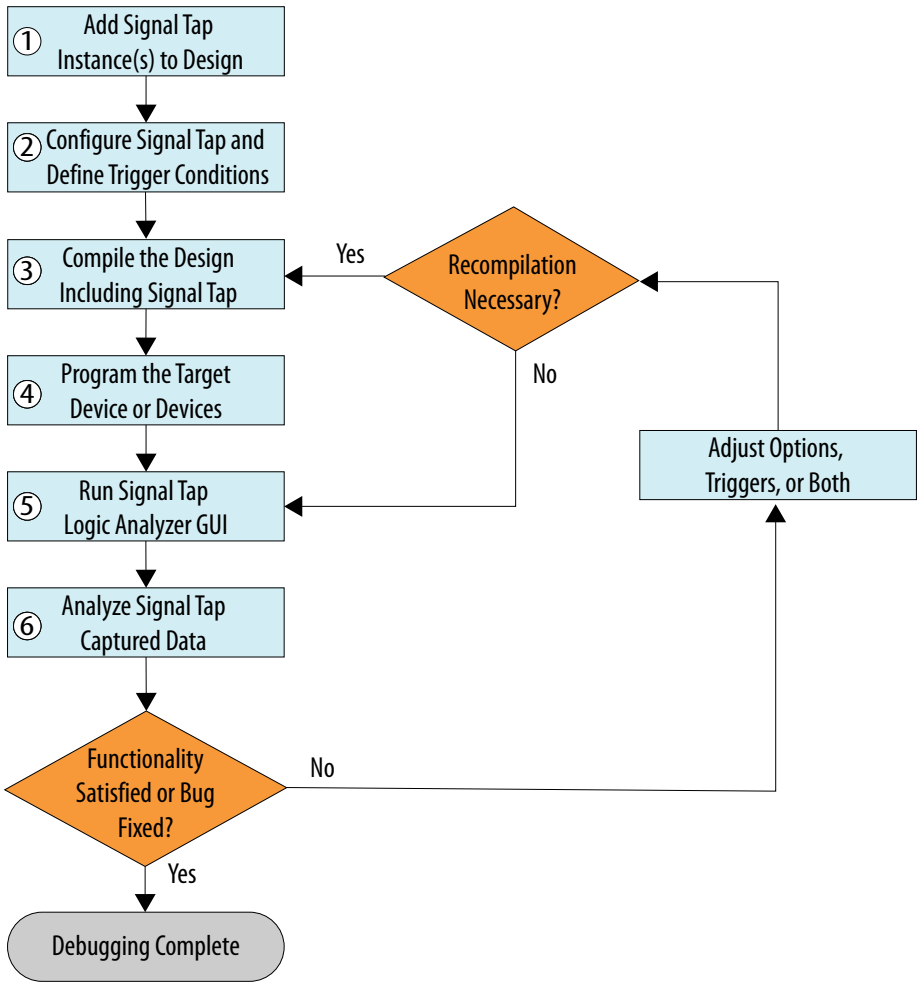
2.2. Signal Tap Debugging Flow

To use the Signal Tap logic analyzer to debug your design, you compile your design that includes one or more Signal Tap instances that you define, configure the target device, and then run the logic analyzer to capture and analyze signal data.

When Should I Add Signal Tap to the Design?

It is best to add the Signal Tap logic analyzer to your design early in the design flow to help prevent later difficulty in fitting the Signal Tap logic into the target device. If you add Signal Tap late in the design cycle, you may have difficulty with fitting if the device is already at 90-95% full. However, you can use the ECO compilation feature to add Signal Tap as soon as you initially create the design, even before adding nodes or running synthesis. This technique allows you to more easily make the ECO connections later if needed. Refer to *Using the ECO Compilation Flow* in *Intel Quartus Prime Pro Edition User Guide: Design Optimization*.

Figure 21. Signal Tap Debugging Flow



The following steps describe the Signal Tap debugging flow in detail:

- Step 1: Add the Signal Tap Logic Analyzer to the Project on page 34
- Step 2: Configure the Signal Tap Logic Analyzer on page 39
- Step 3: Compile the Design and Signal Tap Instances on page 82
- Step 4: Program the Target Hardware on page 85
- Step 5: Run the Signal Tap Logic Analyzer on page 86
- Step 6: Analyze Signal Tap Captured Data on page 92

Related Information

Using the ECO Compilation Flow in *Intel Quartus Prime Pro Edition User Guide: Design Optimization*

2.3. Step 1: Add the Signal Tap Logic Analyzer to the Project

To debug a design using the Signal Tap logic analyzer, you must first define one or more Signal Tap instances and add them to your project. You then compile the Signal Tap instances, along with your design. You can define a Signal Tap instance in the Signal Tap logic analyzer GUI or by HDL instantiation.

To help you get started quickly, the Signal Tap logic analyzer GUI includes preconfigured templates for various trigger conditions and applications. You can then modify the settings the template applies and adjust trigger conditions in the Signal Tap logic analyzer GUI.

Alternatively, you can define a Signal Tap instance by parameterizing an instance of the Signal Tap Logic Analyzer Intel FPGA IP, and then instantiating the Signal Tap entity or module in an HDL design file.

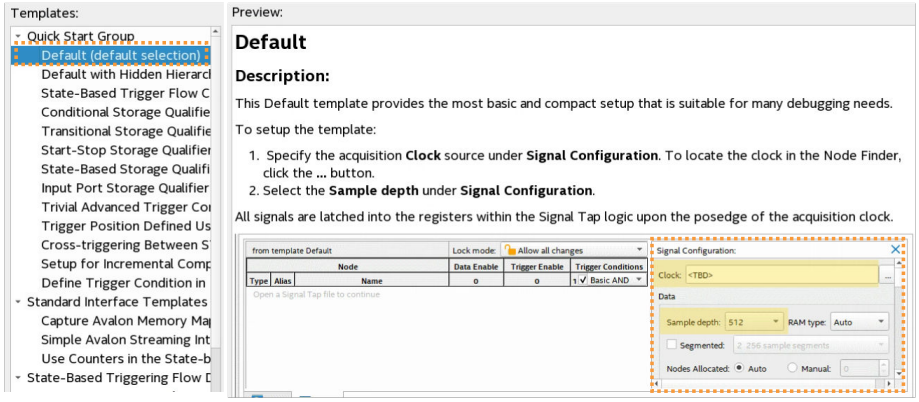
If you want to monitor multiple clock domains simultaneously, you can add additional instances of the logic analyzer to your design, limited only by the available resources in your device.

2.3.1. Creating a Signal Tap Instance with the Signal Tap GUI

When you define one or more Signal Tap instances in the GUI, Signal Tap stores the trigger and signal configuration settings in a Signal Tap Logic Analyzer File (`.stp`). You can open a `.stp` to reload that Signal Tap configuration.

1. Open a project and run **Analysis & Synthesis** on the Compilation Dashboard.
2. To create a Signal Tap instance with the Signal Tap logic analyzer GUI, perform one of the following:
   - Click **Tools ➤ Signal Tap Logic Analyzer**.
   - Click **File ➤ New ➤ Signal Tap Logic Analyzer File**.

Figure 22. Signal Tap file Templates



3. Select a Signal Tap file template. The **Preview** describes the setup and **Signal Configuration** the template applies. Refer to Signal Tap File Templates on page 116.

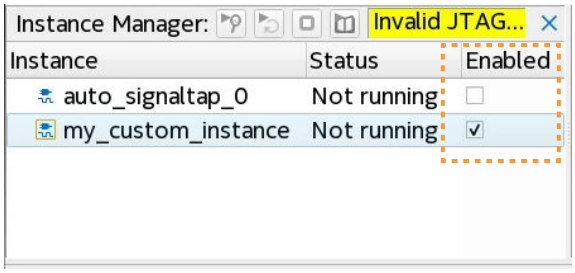
4. Click **Create**. The Signal Tap logic analyzer GUI opens with the template options preset for the Signal Tap instance.
5. Under **Signal Configuration**, specify the acquisition **Clock** and optionally modify other settings, as Step 2: Configure the Signal Tap Logic Analyzer on page 39 describes.
6. When you save or close the Signal Tap instance, click **Yes** when prompted to add the Signal Tap instance to the project.

2.3.1.1. Managing Signal Tap Instances

You can manage the properties of different Signal Tap instances in the **Instance Manager** pane. You can enable or disable one or more instances to specify whether your project includes the instance the next time you run compilation. If you enable or disable instances, you must recompile the design to implement the changes.

The **Instance Manager** toolbar allows you to **Run Analysis** and **Stop Analysis**, or start **Autorun Analysis**, which starts the Signal Tap logic analyzer in a repetitive acquisition mode, providing continuous display update.

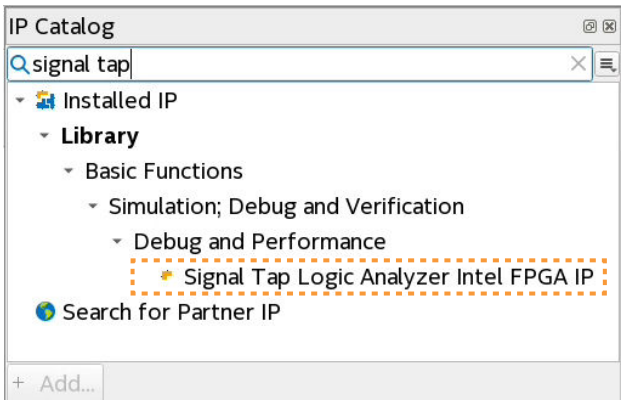
Figure 23. Enable and Disable Signal Tap Instances in Instance Manager



2.3.2. Creating a Signal Tap Instance by HDL Instantiation

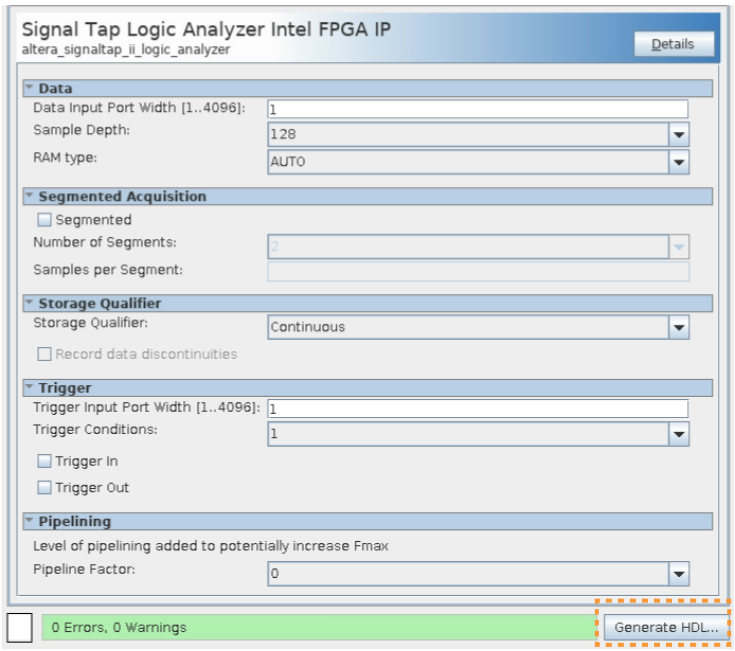
You can create a Signal Tap Instance by HDL instantiation, rather than using the Signal Tap logic analyzer GUI. When you use HDL instantiation, you first parameterize and instantiate the Signal Tap Logic Analyzer Intel FPGA IP in your RTL. Next, you compile the design and IP, and run a Signal Tap analysis using the generated `.stp` file. Follow these steps to create a Signal Tap instance by HDL instantiation:

Figure 24. Signal Tap Logic Analyzer Intel FPGA IP



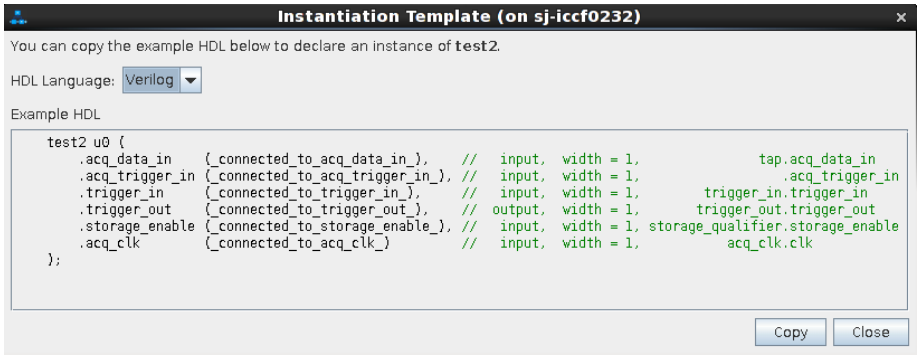
1. From the Intel Quartus Prime IP Catalog (**View ➤ IP Catalog**), locate and double-click the **Signal Tap Logic Analyzer Intel FPGA IP**.
2. In the **New IP Variant** dialog box, specify the **File Name** for your Signal Tap instance, and then click **Create**. The IP parameter editor displays the available parameter settings for the Signal Tap instance.
3. In the parameter editor, specify the **Data**, **Segmented Acquisition**, **Storage Qualifier**, **Trigger**, and **Pipelining** parameters, as Signal Tap Intel FPGA IP Parameters on page 37 describes.
4. Click Generate HDL. The parameter editor generates the HDL implementation of the Signal Tap instance according to your specifications.

Figure 25. IP Parameter Editor



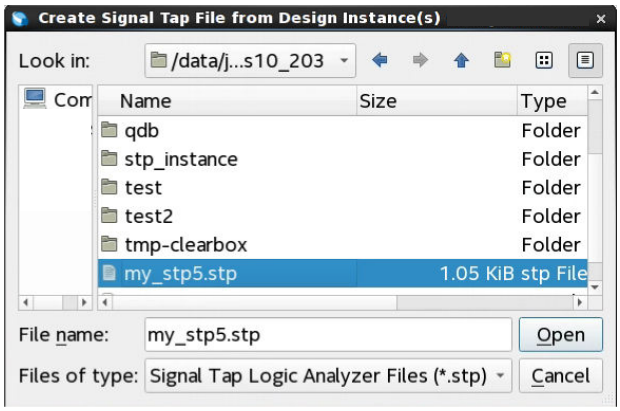
5. To instantiate the Signal Tap instance in your RTL, click **Generate ➤ Show Instantiation Template** in the parameter editor. **Copy** the **Instantiation Template** contents into your RTL.

Figure 26. Signal Tap Logic Analyzer Intel FPGA IP Instantiation Template



6. Run at least the Analysis & Synthesis stage of the Compiler to synthesize the RTL (including Signal Tap instance) by clicking **Processing ➤ Start ➤ Start Analysis & Synthesis**. Alternatively, you can run full compilation and the Assembler at this point if ready.
7. When the Compiler completes, click **Create/Update ➤ Create Signal Tap File from Design Instance** to create a `.stp` file for analysis in the Signal Tap logic analyzer GUI.

Figure 27. Create Signal Tap File from Design Instances Dialog Box



Note: If your project contains partial reconfiguration partitions, the PR partitions display in a tree view. Select a partition from the view, and click **Create Signal Tap file**. The resulting `.stp` file that generates contains all HDL instances in the corresponding PR partition. The resulting `.stp` file does not include the instances in any nested partial reconfiguration partition.

8. To analyze the Signal Tap instance, click **File ➤ Open** and select the `.stp` file. The Signal Tap instance opens in the Signal Tap logic analyzer GUI for analysis. All the fields are read-only, except runtime-configurable trigger conditions.
9. Modify any runtime-configurable trigger conditions, as Runtime Reconfigurable Options on page 89 describes.

2.3.2.1. Signal Tap Intel FPGA IP Parameters

The Signal Tap Intel FPGA IP has the following parameters:

Table 8. Signal Tap Intel FPGA IP Parameters

Parameter Groups	Parameter Descriptions
Data	• **Data Input Port Width**—from 1 to 4096. Default is 1. • **Sample Depth**—number of samples to collect from 0-128K. Default is 128. • **RAM type**—memory type for sample collection and storage. The **Auto** (default), **M20K/M10K/M9K**, **MLAB/LUTRAM**, and **M144K** options are available.
Segmented Acquisition	Specifies options for organizing the captured data buffer:
	continued...

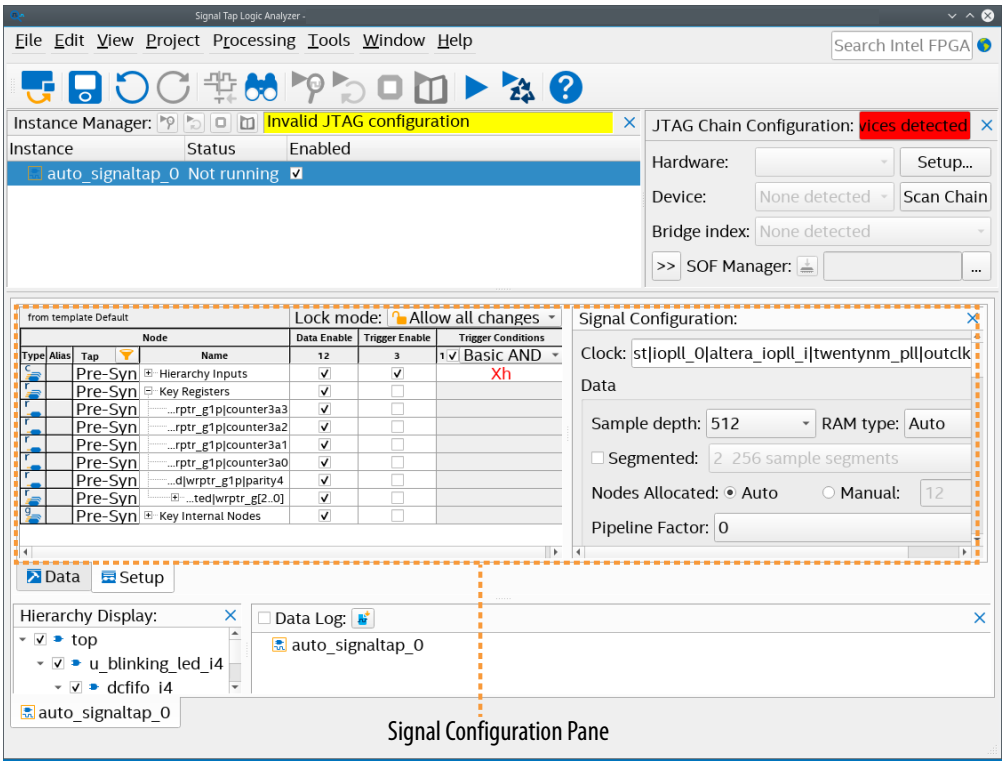
Parameter Groups	Parameter Descriptions
	• **Segmented**—the memory space is split into separate buffers. Each buffer acts as a separate FIFO with its own set of trigger conditions, and behaves as a non-segmented buffer. Only a single buffer is active during an acquisition. Default is off. • **Number of Segments**—specifies the number of segments in each memory space. Default is 2. • **Samples per Segments**—the number of samples Signal Tap captures per segment. Default is 64.
Storage Qualifier	Specifies the **Continuous** or **Input Port** method, and whether to **Record data discontinuities**.
Trigger	• **Trigger Input Port Width**—from 1 to 4096. Default is 1. • **Trigger Conditions**—number of trigger conditions or levels you are implementing 1-10. Default is 1. • **Trigger In**—enables and creates a port for the Trigger In. • **Trigger Out**—enables and creates a port for the Trigger Out.
Pipelining	The Pipeline Factor specifies the levels of pipelining added for potential f_{MAX} improvement from 0 to 5. Default is 0.

2.4. Step 2: Configure the Signal Tap Logic Analyzer

You must configure the Signal Tap logic analyzer before you can capture and analyze data. You can configure instances of the Signal Tap logic analyzer by specifying options in the Signal Tap **Signal Configuration** pane.

When you use the available Signal Tap templates to create a new Signal Tap instance, the template specifies many of the initial option values automatically.

Figure 28. Signal Tap Logic Analyzer Signal Configuration Pane



Basic configuration of the Signal Tap logic analyzer includes specifying values for the following options:

- Preserving Signals for Monitoring and Debugging on page 40
- Specifying the Clock, Sample Depth, and RAM Type on page 42
- Specifying the Buffer Acquisition Mode on page 43
- Adding Signals to the Signal Tap Logic Analyzer on page 45
- Defining Trigger Conditions on page 52
- Specifying Pipeline Settings on page 75
- Filtering Relevant Samples on page 75
- Managing Multiple Signal Tap Configurations on page 101

Related Information

Preventing Changes that Require Full Recompilation on page 42

2.4.1. Preserving Signals for Monitoring and Debugging

The Compiler optimizes the RTL signals during synthesis and place-and-route. Unless preserved, the signal names in your RTL may not exist in the post-fit netlist after signal optimizations. For example, the compilation process can merge duplicate registers, or add tildes (~) to net names that fan-out from a node.

To ensure that specific nodes in your RTL are available for Signal Tap debugging after synthesis and place-and-route, you can apply the `preserve_for_debug` attribute to the signals of interest in your RTL, and also specify the **Enable preserve for debug assignments** project `.qsf` setting. Refer to `.qsf` syntax in Debug Signal Preservation Methods.

When you preserve signals using this technique, the Compiler generates the Preserve for Debug Assignments report following synthesis that shows the status and name of all nodes with the `preserve_for_debug` attribute in your RTL.

Follow these steps to preserve signals for monitoring and debugging:

1. In your design RTL, mark signals that you want to preserve with the `preserve_for_debug` attribute:

Figure 29. preserve_for_debug Attribute

```
module blinking_led_2s(
    output value,
    input clk1,
    input clk2);

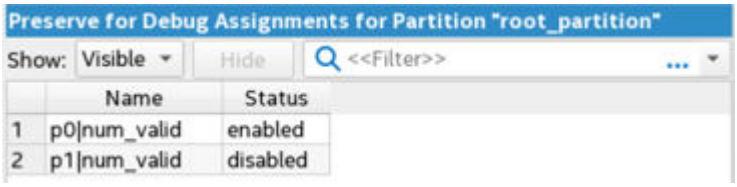
    reg [32:0] count_in;
    reg [32:0] count_out;
    reg value_in;
    reg  value_out;
    wire fifo_out;
    wire fifo_empty;
    wire fifo_rreq;
    (* preserve_for_debug *) reg fifo_wreq;
```

2. Open the project containing Signal Tap in the Intel Quartus Prime software and perform one of the following:
   - To enable preservation and reporting for specific instances, click **Assignments ➤ Assignment Editor**, and then specify the **Enable preserve for debug assignments** assignment **To** any instance of interest.

     Or
   - To enable preservation and reporting project-wide, in **Assignments ➤ Settings ➤ Signal Tap Logic Analyzer**, turn on **Enable preserve for debug assignments**.(1)
3. To synthesize the design, on the Compilation Dashboard, click **Analysis & Synthesis**. The Compilation Report appears when synthesis is complete.
4. To view the results of signal preservation, open the Preserve for Debug Assignments report located in the **Synthesis ➤ Partition <name> ➤ Preserve for Debug** report folder.

(1) The global project setting has a more limited impact and does not preserve signals that would otherwise be optimized away in their local context.

Figure 30. Preserve for Debug Assignments Report



5. Run full compilation to perform place and route of the design and Signal Tap instance, as Step 3: Compile the Design and Signal Tap Instances on page 82 describes. The debug signals that you preserve in step 2 persist through the Fitter into the finalized compilation database.
6. Optionally, make some incremental changes to the Signal Tap configuration without running full recompilation, as Changing the Post-Fit Signal Tap Target Nodes on page 86 describes.

Table 9. Debug Signal Preservation Methods

Method	Description	Example
`preserve_for_debug_enable`	Set this assignment to **On** to preserve any nodes or hierarchies marked with `preserve_for_debug`. If set to **Off** or not used, any `preserve_for_debug` assignments are ignored. Use this as a quick way to disable all debug node preservation when optimizing a completed design. The Compiler reports these nodes in the Preserve for Debug Assignments report following compilation.	`set_instance_assignment -name PRESERVE_FOR_DEBUG_ENABLE ON`
`preserve_for_debug` (**Enable preserve for debug assignments** in the Assignment Editor)	Instance-specific `.qsf` assignment that overrides the global assignment and enables preservation of all types of nodes through synthesis post-synthesis or post-fit debugging purposes. When **On**, this assignment enables preservation for the hierarchy that you specify. You can enable or disable this with the **Preserve signal for debug** assignment in the Assignment Editor. The Compiler reports these nodes in the Preserve for Debug Assignments report following compilation.	`set_instance_assignment -name PRESERVE_FOR_DEBUG ON -to <node hpath>`

Note: For more information about preserving signals, refer to *Preserving Registers During Synthesis*, in the *Intel Hyperflex™ Architecture High-Performance Design Handbook* and *Preserving a System Module, Interface, or Port for Debugging* in the *Intel Quartus Prime Pro Edition User Guide: Platform Designer*.

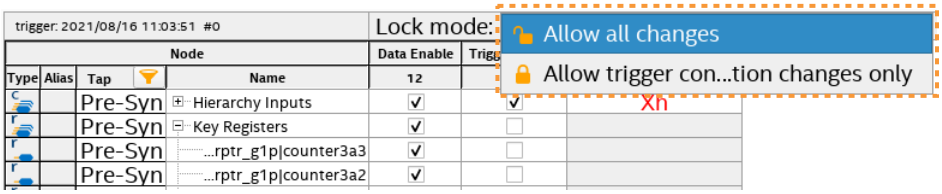
2.4.2. Preventing Changes that Require Full Recompilation

Making some types of changes to the Signal Tap configuration require full recompilation to implement. If you want to ensure that you make no changes to the Signal Tap configuration that require full recompilation, select **Allow trigger condition changes only** for the **Lock mode**. Alternatively, you can enable **Allow all changes**, including those changes that require full compilation or recompilation to implement.

Figure 31. Allow Trigger Conditions Change Only



Related Information

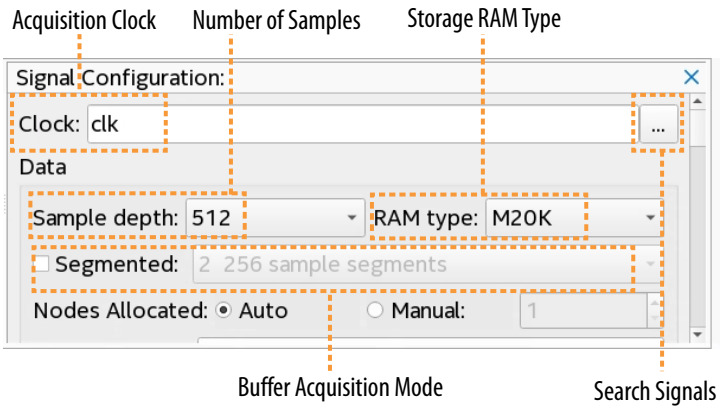
Recompiling Only Signal Tap Changes on page 82

2.4.3. Specifying the Clock, Sample Depth, and RAM Type

You must specify options for the acquisition clock, sample depth, and data storage on the **Signal Configuration** pane before using Signal Tap.

Note: The Signal Tap file templates automatically specify appropriate initial values for some of these options.

Figure 32. Clock, Sample Depth, and Data Storage Options



Specifying the Acquisition Clock

Signal Tap samples data on each positive (rising) edge of the acquisition clock. Therefore, Signal Tap requires a clock signal from your design to control the logic analyzer data acquisition. For best data acquisition, specify a global, non-gated clock that is synchronous to the signals under test. Refer to the Timing Analysis section of the Compilation Report for the maximum frequency of the logic analyzer clock.

- To specify the acquisition clock signal, enter a signal name from your design for the **Clock** setting in **Single Configuration**.

Note: Consider the following when specifying the acquisition clock:

- If you do not assign an acquisition clock, Signal Tap automatically creates clock pin `auto_stp_external_clk`. You must then make a pin assignment to this signal, and ensure that a clock signal in your design drives the acquisition clock.
- Using a transceiver recovered clock as the acquisition clock can cause incorrect or unexpected behavior, particularly when the transceiver recovered clock is the acquisition clock with the power-up trigger feature.
- Specifying a gated acquisition clock can result in unexpected data that does not accurately reflect the behavior of your design.
- Signal Tap does not support sampling on the negative (falling) clock edge.

Specifying Sample Depth

The sample depth determines the number of samples the logic analyzer captures and stores in the data buffer, for each signal. In cases with limited device memory resources, you can reduce the sample depth to reduce resource usage.

- To specify the sample depth, select the number of samples from the **Sample depth** list under **Single Configuration**. Available sample depth range is from 0 to 128K.

Specifying the RAM Type

You can specify the RAM type and buffer acquisition mode for storage of Signal Tap logic analyzer acquisition data. When you allocate the Signal Tap logic analyzer buffer to a particular RAM block, the entire RAM block becomes a dedicated resource for the logic analyzer.

- To specify the RAM type, select a **Ram type** under **Single Configuration**. Available settings are **Auto**, **MLAB**, or **M20K** RAM.

Use RAM selection to preserve a specific memory block for your design, and allocate another portion of memory for Signal Tap data acquisition. For example, if your design has an application that requires a large block of memory resources, such as a large instruction or data cache, use MLAB blocks for data acquisition and leave M20k blocks for your design.

Related Information

- Adding Nios II Processor Signals with a Plug-In on page 50
- Managing Device I/O Pins, Intel Quartus Prime Pro Edition User Guide: Design Constraints

2.4.4. Specifying the Buffer Acquisition Mode

You can specify how Signal Tap organizes the data capture buffer to potentially reduce the amount of memory that Signal Tap requires for data acquisition.

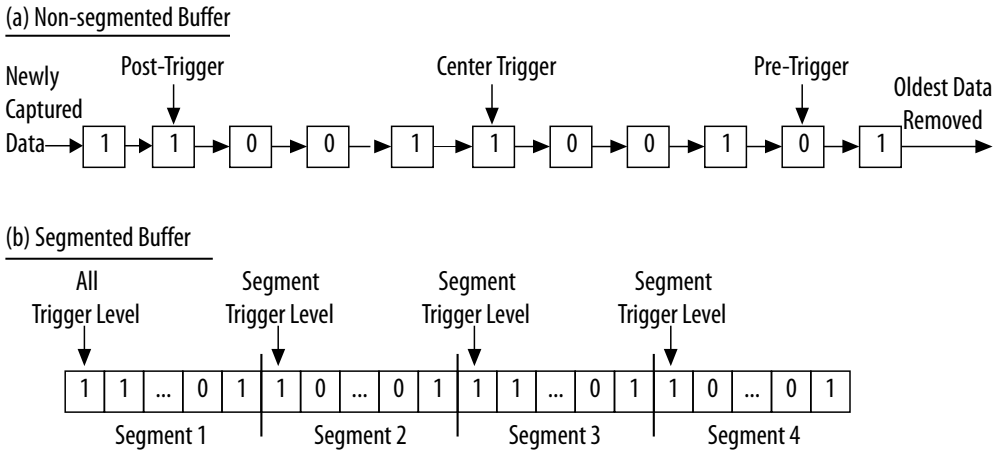
The Signal Tap logic analyzer supports either a non-segmented (or circular) buffer and a segmented buffer.

- **Non-segmented buffer**—the Signal Tap logic analyzer treats the entire memory space as a single FIFO, continuously filling the buffer until the logic analyzer reaches the trigger conditions that you specify.
- **Segmented buffer**—the memory space is split into separate buffers. Each buffer acts as a separate FIFO with its own set of trigger conditions, and behaves as a non-segmented buffer. Only a single buffer is active during an acquisition. The Signal Tap logic analyzer advances to the next segment after the trigger condition or conditions for the active segment has been reached.

When using a non-segmented buffer, you can use the storage qualification feature to determine which samples are written into the acquisition buffer. Both the segmented buffers and the non-segmented buffer with the storage qualification feature help you maximize the use of the available memory space.

Figure 33. Buffer Type Comparison in the Signal Tap Logic Analyzer

The figure illustrates the differences between the two buffer types.



Both non-segmented and segmented buffers can use a preset trigger position (Pre-Trigger, Center Trigger, Post-Trigger). Alternatively, you can define a custom trigger position using the **State-Based Triggering** tab, as Specify Trigger Position on page 61 describes.

2.4.4.1. Non-Segmented Buffer

The non-segmented buffer is the default buffer type in the Signal Tap logic analyzer.

At runtime, the logic analyzer stores data in the buffer until the buffer fills up. From that point on, new data overwrites the oldest data, until a specific trigger event occurs. The amount of data the buffer captures after the trigger event depends on the **Trigger position** setting:

- To capture more data from before the trigger occurs, select **Post trigger position** from the list.
- To capture all data from after the trigger occurs, select **Pre trigger position**.
- To center the trigger position in the data, select **Center trigger position**.

Alternatively, use the custom State-based triggering flow to define a custom trigger position within the capture buffer.

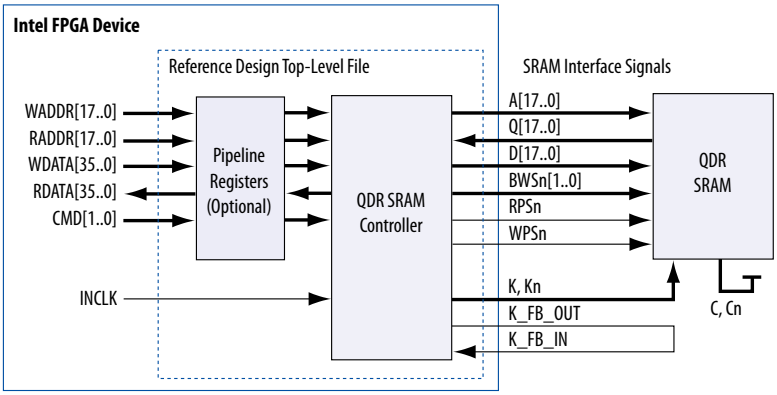
2.4.4.2. Segmented Buffer

In a segmented buffer, the acquisition memory is split into segments of even size, and you define a set of trigger conditions for all segments. Each segment acts as a non-segmented buffer. A segmented buffer allows you to debug systems that contain relatively infrequent recurring events.

If you want to have separate trigger conditions for each of the buffer segments, you must use the state-based trigger flow. The figure shows an example of a segmented buffer system.

Figure 34. System that Generates Recurring Events

In the following example, to ensure that the correct data is written to the SRAM controller, monitor the RDATA port whenever the address `H'0F0F0F0F` is sent into the RADDR port.



The buffer acquisition feature allows you to monitor multiple read transactions from the SRAM device without running the Signal Tap logic analyzer again. You can split the memory to capture the same event multiple times, without wasting allocated memory. The buffer captures as many cycles as the number of segments you define under the **Data** settings in the **Signal Configuration** pane.

To enable and configure buffer acquisition, select **Segmented** in the Signal Tap logic analyzer Editor and choose the number of segments to use. In the example in the figure, selecting 64-sample segments allows you to capture 64 read cycles.

Related Information

Viewing Capture Data Using Segmented Buffers on page 93

2.4.5. Adding Signals to the Signal Tap Logic Analyzer

You add the signals that you want to monitor to the node list in the Signal Tap logic analyzer. You can then select a signals in the node list to define the triggers for the signal.

Adding Pre-Synthesis Signals

You can add expected signals to Signal Tap for monitoring without running synthesis. Pre-synthesis signal names are those names present after Analysis & Elaboration, but before any synthesis optimizations. When you add pre-synthesis signals to Signal Tap

for monitoring, you must make all connections to the Signal Tap logic analyzer before running synthesis. The Compiler then automatically allocates the logic and routing resources to make these connections. For signals driving to and from IOEs, pre-synthesis signal names coincide with the pin's signal names.

Refer to Adding Pre-Synthesis or Post-Fit Nodes on page 46.

Adding Simulator-Aware Signals

You can easily generate a list of simulator-aware, pre-synthesis signals to tap for an entire design hierarchy, and then observe all internal signal states in your RTL simulator. This set of simulator-aware nodes can provide full visibility into other untapped nodes in the design hierarchy. You can then export captured Signal Tap signal data directly into your RTL simulator to observe signal states beyond Signal Tap observability.

Refer to Adding Simulator-Aware Signal Tap Nodes on page 48.

Adding Post-Fit Signals

You can add post-fit signals to Signal Tap for monitoring. Post-fit signal names are those names present in the netlist after physical synthesis optimizations and place-and-route. When you add post-fit signals to Signal Tap for monitoring, you are connecting to actual atoms in the post-fit netlist. You can only monitor signals that exist in the post-fit netlist, and existing routing resources must be available.

In the case of post-fit output signals, monitor the COMBOUT or REGOUT signal that drives the IOE block. For post-fit input signals, signals driving into the core logic coincide with the pin's signal name.

Note: Because NOT-gate push back applies to any register that you monitor, the signal from the atom may be inverted. You can verify the inversion by locating to the signal with the **Locate Node ➤ Locate in Resource Property Editor** or the **Locate Node ➤ Locate in Technology Map Viewer** commands. You can also view post-fit node names in the Resource Property Editor.

Related Information

Signal Tap and Simulator Integration on page 98

2.4.5.1. Adding Pre-Synthesis or Post-Fit Nodes

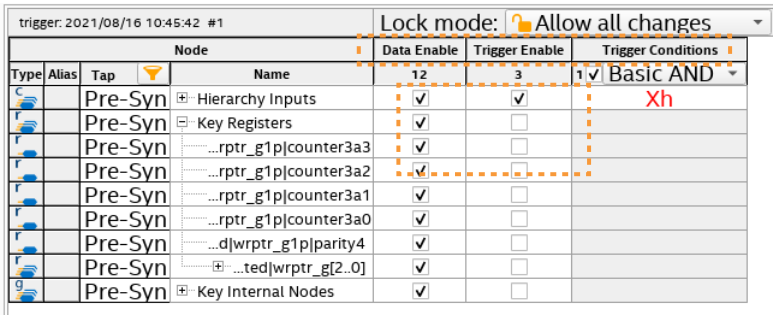
To add one or more pre-synthesis or post-fit signals to the Signal Tap **Node** list for monitoring:

1. Click either of the following commands to generate the pre-synthesis or post-fit design netlist:
   - **Processing ➤ Start ➤ Start Analysis & Elaboration** (generates pre-synthesis netlist)
   - **Processing ➤ Start ➤ Start Fitter** (generates post-fit netlist)
2. In the Signal Tap logic analyzer, Click **Edit ➤ Add Nodes**. The Node Finder appears, allowing you to find and add the signals in your design. The following Filter options are available for finding the nodes you want:

- **Signal Tap: pre-synthesis**—finds signal names present after design elaboration, but before any synthesis optimizations are done. **Signal Tap: pre-synthesis preserved for debug** finds presynthesis signals that you mark with the `preserve_for_debug` pragma, as Preserving Signals for Monitoring and Debugging on page 40 describes.
- **Signal Tap: post-fitting**—finds signal names present after physical synthesis optimizations and place-and-route. **Signal Tap: post-fitting preserved for debug** finds post-fit signals that you mark with the `preserve_for_debug` pragma.

3. In the Node Finder, select one or more nodes that you want to add, and then click the **Copy all to Selected Nodes list** button.
4. Click **Insert**. The nodes are added to the **Setup** tab signal list in the Signal Tap logic analyzer GUI.
5. Specify how the logic analyzer uses the signal by enabling or disabling the **Data Enable**, **Trigger Enable**, or **Storage Enable** option for the signal:
   - **Trigger Enable**—disabling prevents a signal from triggering the analysis, while still showing the signal's captured data.
   - **Data Enable**—disabling prevent capture of data, while still allowing the signal to trigger.

Figure 35. Signal Tap Node List Options for Data Enable and Trigger Enable



6. Define trigger conditions for the Signal Tap nodes, as Defining Trigger Conditions on page 52 describes.

The number of channels available in the Signal Tap window waveform display is directly proportional to the number of logic elements (LEs) or adaptive logic modules (ALMs) in the device. Therefore, there is a physical restriction on the number of channels that are available for monitoring. Signals shown in blue text are post-fit node names. Signals shown in black text are pre-synthesis node names.

After successful Analysis and Elaboration, invalid signals appear in red. Unless you are certain that these signals are valid, remove them from the `.stp` file for correct operation. The Signal Tap Status Indicator also indicates if an invalid node name exists in the `.stp` file.

You can monitor signals only if a routing resource (row or column interconnects) exists to route the connection to the Signal Tap instance. For example, you cannot monitor signals that exist in the I/O element (IOE), because there are no direct routing resources from the signal in an IOE to a core logic element. For input pins, you can monitor the signal that is driving a logic array block (LAB) from an IOE, or, for output pins, you can monitor the signal from the LAB that is driving an IOE.

Note: The Intel Quartus Prime Pro Edition software uses only the instance name, and not the entity name, in the form of:

```
a|b|c
```

not `a_entity:a|b_entity:b|c_entity:c`

2.4.5.2. Adding Simulator-Aware Signal Tap Nodes

Note: This version of the Signal Tap simulator integration feature is a beta release. The following known limitations apply to this beta release:

- Supports only Verilog HDL simulation.
- Supports testbench generation only within the current project directory.

To automatically generate and add a list of simulator-aware signals to the Signal Tap **Node** list for Signal Tap and simulator monitoring, follow these steps:

1. To generate the pre-synthesis design netlist, click **Processing ➤ Start ➤ Start Analysis & Elaboration**.
2. In the Signal Tap logic analyzer, click **Edit ➤ Add Simulator Aware Nodes**. The **Simulator Aware Node Finder** opens, allowing you to specify the following options to find and add the minimum set of nodes to tap to for full visibility into the selected hierarchy's cone of logic:
   a. Click the **Select Hierarchies** button, select one or more design hierarchies that you want to tap, and then click **OK**. The clock domains in the hierarchy appear in the **Clock Domains** list.
   b. Under **Clock Domains**, enable only the domains of interest. If you select multiple clock domains, Signal Tap creates an instance for each domain.
   c. Click the **Search** button. All nodes required to provide full visibility into the selected hierarchy automatically appear enabled in the **Total nodes to tap** list. Disabling any of the simulator-aware nodes may reduce simulation visibility.
   d. Click the **Insert** button. The enabled signals in the **Total nodes to tap** list are copied to the Signal Tap **Node** list, and the acquisition clock updates according to the simulator-aware signal data. Refer to Add Simulator-Aware Node Finder Settings on page 50.

Figure 36. Simulator Aware Node Finder

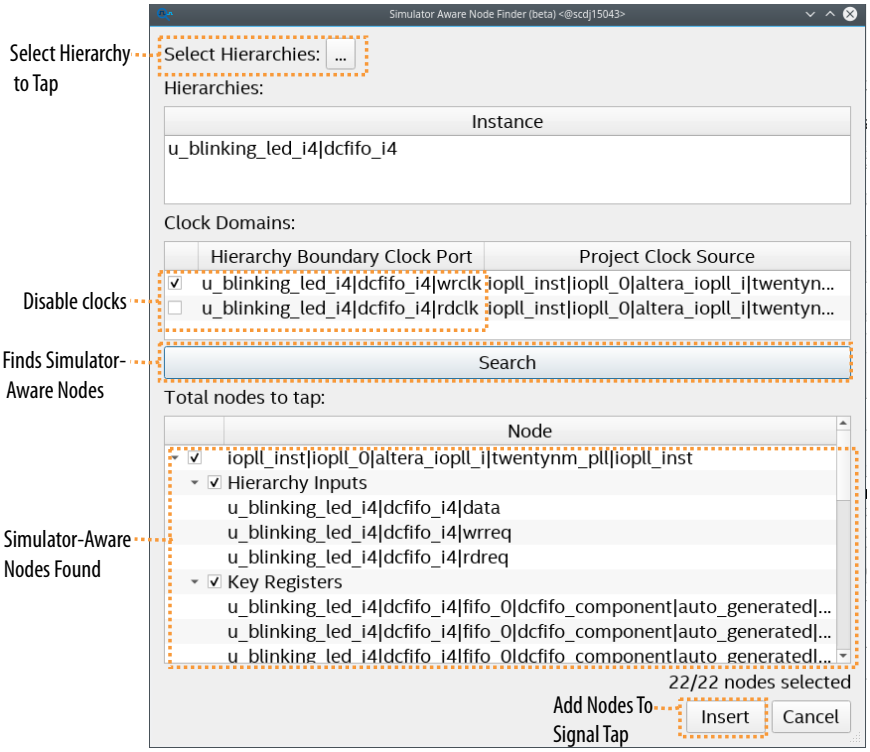


Figure 37. Simulator-Aware Nodes Copied to Signal Tap Window

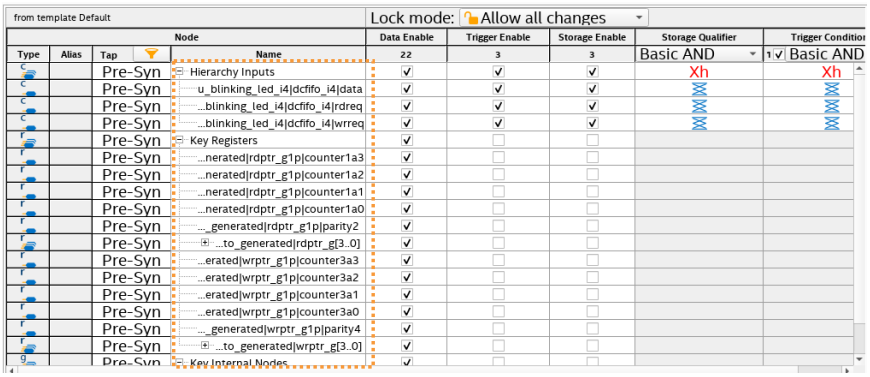


3. Modify trigger conditions for the Signal Tap nodes, as Defining Trigger Conditions on page 52 describes.
4. Compile the design and Signal Tap instance, Step 3: Compile the Design and Signal Tap Instances on page 82 describes.
5. Program the target hardware, as Step 4: Program the Target Hardware on page 85 describes.
6. Run the Signal Tap logic analyzer, as Step 5: Run the Signal Tap Logic Analyzer on page 86 describes.
7. Generate a simulation testbench from Signal Tap capture data, as Generating a Simulation Testbench from Signal Tap Data on page 98 describes.

2.4.5.2.1. Add Simulator-Aware Node Finder Settings

The following options are available for searching and adding simulator aware nodes to Signal Tap for the purpose of generating an RTL simulation testbench from Signal Tap data. The default values derive from Signal Tap signal data and are set correctly for most scenarios.

Table 10. Add Simulator Aware Node Finder Settings (Signal Tap Logic Analyzer)

Name	Description
Select Hierarchies	Specifies the design hierarchy from which to extract simulator-aware nodes. Select one or more design hierarchies that you want to tap. The clock domains of the hierarchy appear in the **Clock Domains** list. Only nodes from the hierarchy you specify are added.
Clock Domains	Specifies the clock domains to include in the simulator-aware node finder. Turn on only the domains that you want to include.
Search button	Starts the search for simulator-aware nodes according to the specifications in this dialog box. Search results appear in the **Total nodes to tap** list.
Total nodes to tap	Displays the results of the simulator-aware node name search, showing all of the names in the hierarchy enabled by default. Turn the node names on to include or off to exclude from the list of nodes added to Signal Tap. Disabling any of the simulator-aware nodes may reduce simulation visibility.
Insert Button	Copies the enabled signals in the **Total nodes to tap** list to the Signal Tap **Node** list, and the acquisition clock updates according to the simulator-aware signal data.

2.4.5.3. Adding Nios II Processor Signals with a Plug-In

You can use a plug-in to automatically add relevant signals for the Nios II processor for monitoring, rather than adding the signals manually with the Node Finder. The plug-in provides preset mnemonic tables for trigger creation and viewing, as well as the ability to disassemble code in captured data.

Note: This feature does not yet support the Nios V embedded processor.

The Nios II plug-in creates one mnemonic table in the **Setup** tab and two tables in the **Data** tab:

- **Nios II Instruction** (**Setup** tab)—capture all the required signals for triggering on a selected instruction address.
- **Nios II Instance Address** (**Data** tab)—display address of executed instructions in hexadecimal format or as a programming symbol name if defined in an optional Executable and Linking Format (`.elf`) file.
- **Nios II Disassembly** (**Data** tab)—display disassembled code from the corresponding address.

To add Nios II IP signals to the logic analyzer using a plug-in, perform the following steps after running Analysis and Elaboration on your design:

1. In the Signal Tap logic analyzer, right-click the node list, and then click **Add Nodes with Plug-In ➤ Nios II**.
2. Select the IP that contains the signals you want to monitor with the plug-in, and click **OK**.

— If all the signals in the plug-in are available, a dialog box might appear, depending on the plug-in, where you can specify options for the plug-in.

3. With the Nios II plug-in, you can optionally select an `.elf` containing program symbols from your Nios II Integrated Development Environment (IDE) software design. Specify options for the selected plug-in, and click **OK**.

2.4.5.4. Signals Unavailable for Signal Tap Debugging

Some post-fit signals in your design are unavailable for Signal Tap debugging. The Node Finder's **Signal Tap: post-fitting** filter does not return nodes that are unavailable for Signal Tap debugging.

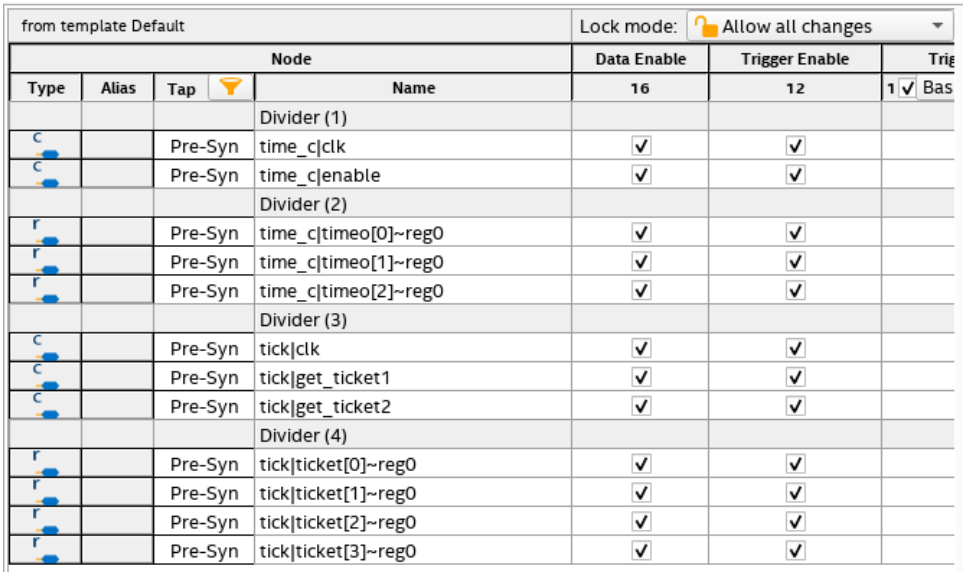
The following signal types are unavailable for Signal Tap debugging:

- **Post-fit output pins**—You cannot monitor a post-fit output or bidirectional pin directly. To make an output signal visible, monitor the register or buffer that drives the output pin.
- **Carry chain signals**—You cannot monitor the carry out (`cout0` or `cout1`) signal of a logic element. Due to architectural restrictions, the carry out signal can only feed the carry in of another LE.
- **JTAG signals**—You cannot monitor the JTAG control (`TCK`, `TDI`, `TDO`, or `TMS`) signals.
- **LVDS**—You cannot monitor the data output from a serializer/deserializer (SERDES) block.
- **DQ**, **DQS signals**—You cannot directly monitor the `DQ` or `DQS` signals in a DDR or DDRII design.

2.4.5.5. Organizing Signals in the Signal Tap Logic Analyzer

Use dividers in the node list to separate and categorize your signals into groups to make reviewing the node table easier. You can move and rename dividers in the node table at any time.

Figure 38. Example Signal Tap Logic Analyzer node table that shows a lists of nodes and dividers



- To add a divider, right-click a node in the node table and select **Add Divider**.

  The new divider is added immediately above the selected node. The divider is assigned a name that you can change at any time.
- To rename a divider, right-click the divider that you want to rename and select **Rename**.
- To move a divider, drag-and-drop the divider to its new location.
- To delete a divider, right-click the divider and select **Delete**.

2.4.6. Defining Trigger Conditions

By default, the Signal Tap logic analyzer captures data continuously from the signals you specify while the logic analyzer is running. To capture and store only specific signal data, you can specify conditions that *trigger* the start or stop of data capture. A trigger activates—that is, the logic analyzer stops and displays the data—when the signals you specify reach the trigger conditions that you define.

The Signal Tap logic analyzer allows you to define trigger conditions that range from very simple, such as the rising edge of a single signal, to very complex, involving groups of signals, extra logic, and multiple conditions. Additionally, you can specify Power-Up Triggers to capture data from trigger events occurring immediately after the device enters user-mode after configuration.

2.4.6.1. Basic Trigger Conditions

If you select the **Basic AND** or **Basic OR** trigger type, you must specify the trigger pattern for each signal that you add.

To specify the trigger pattern, right-click the **Trigger Conditions** column and click **Don't Care**, **Low**, **High**, **Falling Edge** , **Rising Edge**, or **Either Edge**.

For buses, type a pattern in binary, or right-click and select **Insert Value** to enter the pattern in other number formats. Note that you can enter X to specify a set of "don't care" values in either your hexadecimal or your binary string. For signals in the `.stp` file that have an associated mnemonic table, you can right-click and select an entry from the table to specify pre-defined conditions for the trigger.

When you add signals through plug-ins, you can create basic triggers using predefined mnemonic table entries. For example, with the Nios II plug-in, if you specify an `.elf` file from your Nios II IDE design, you can type the name of a function from your Nios II code. The logic analyzer triggers when the Nios II instruction address matches the address of the code function name that you specify.

Data capture stops and the logic analyzer stores the data in the buffer when the logical AND of all the signals for a given trigger condition evaluates to TRUE.

2.4.6.2. Nested Trigger Conditions

When you specify a set of signals as a nested group (group of groups) with the **Basic OR** trigger type, the logic analyzer generates an advanced trigger condition. This condition sorts the signals within groups to minimize the need to recompile your design. If you always retain the parent-child relationship of nodes, the advanced trigger condition does not change. You can modify the sibling relationships of nodes, without requiring recompilation.

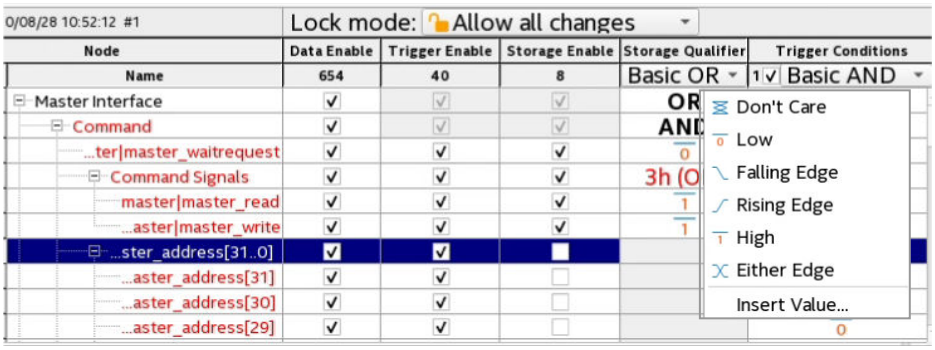
The evaluation precedence of a nested trigger condition starts at the bottom-level with the leaf-groups. The logic analyzer uses the resulting logic value to compute the parent group's logic value. If you manually set the value of a group, the logic value of the group's members doesn't influence the result of the group trigger.

To create a nested trigger condition:

1. Select **Basic OR** under **Trigger Conditions**.
2. In the **Setup** tab, select several nodes. Include groups in your selection.
3. Right-click the **Setup** tab and select **Group**.
4. Select the nested group and right-click to set a group trigger condition that applies the reduction **AND**, **OR**, **NAND**, **NOR**, **XOR**, **XNOR**, or logical **TRUE** or **FALSE**.

   Note: You can only select OR and AND group trigger conditions for bottom-level groups (groups with no groups as children).

Figure 39. Applying Trigger Condition to Nested Group



2.4.6.3. Comparison Trigger Conditions

The **Comparison** trigger allows you to compare multiple grouped bits of a bus to an expected integer value by specifying simple comparison conditions on the bus node. The **Comparison** trigger preserves all the trigger conditions that the **Basic OR** trigger includes. You can use the **Comparison** trigger in combination with other triggers. You can also switch between **Basic OR** trigger and **Comparison** trigger at run-time, without the need for recompilation.

Signal Tap logic analyzer supports the following types of **Comparison** trigger conditions:

- **Single-value comparison**—compares a bus node's value to a numeric value that you specify. Use one of these operands for comparison: >, >=, ==, <=, <, !=. Returns 1 when the bus node matches the specified numeric value.
- **Interval check**—verifies whether a bus node's value confines to an interval that you define. Returns 1 when the bus node's value lies within the specified bounded interval.

Follow these rules when using the **Comparison** trigger condition:

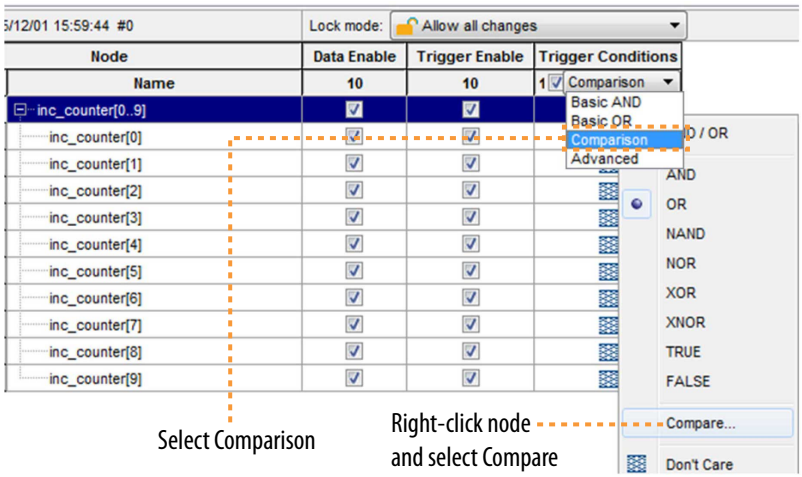
- Apply the **Comparison** trigger only to bus nodes consisting of leaf nodes.
- Do not form sub-groups within a bus node.
- Do not enable or disable individual trigger nodes within a bus node.
- Do not specify comparison values (in case of single-value comparison) or boundary values (in case of interval check) exceeding the selected node's bus-width.

2.4.6.3.1. Specifying the Comparison Trigger Conditions

Follow these steps to specify the **Comparison** trigger conditions:

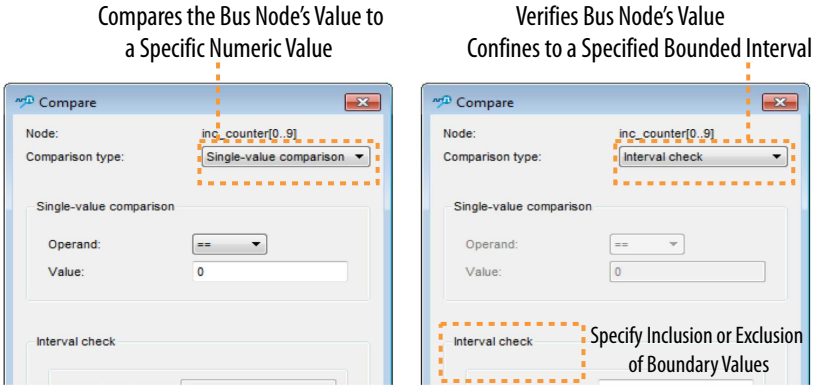
1. From the **Setup** tab, select **Comparison** under **Trigger Conditions**.
2. Right-click the node in the trigger editor, and select **Compare**.
3. Select the **Comparison type** from the Compare window.
   - If you choose **Single-value comparison** as your comparison type, specify the operand and value.
   - If you choose **Interval check** as your comparison type, provide the lower and upper bound values for the interval.

Figure 40. Selecting the Comparison Trigger Condition



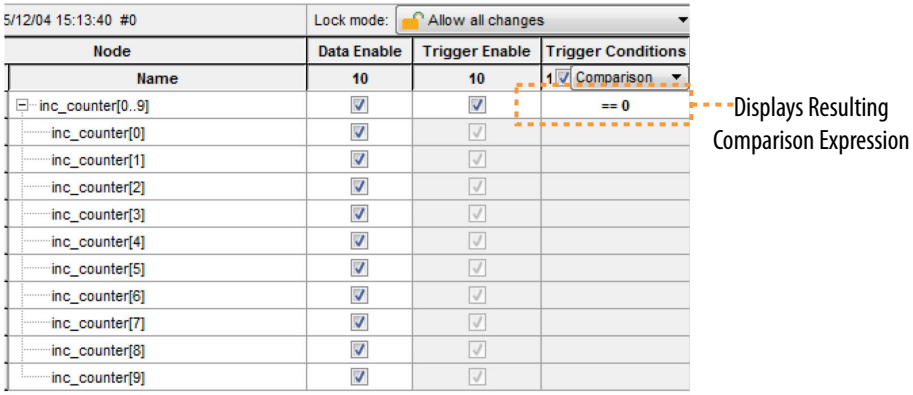
You can also specify if you want to include or exclude the boundary values.

Figure 41. Specifying the Comparison Values



4. Click **OK**. The trigger editor displays the resulting comparison expression in the group node condition text box.

Figure 42. Resulting Comparison Condition in Text Box



2.4.6.4. Advanced Trigger Conditions

To capture data for a given combination of conditions, build an advanced trigger. The Signal Tap logic analyzer provides the **Advanced Trigger** tab, which helps you build a complex trigger expression using a GUI. Open the **Advanced Trigger** tab by selecting **Advanced** in the **Trigger Conditions** list.

Figure 43. Accessing the Advanced Trigger Condition Tab

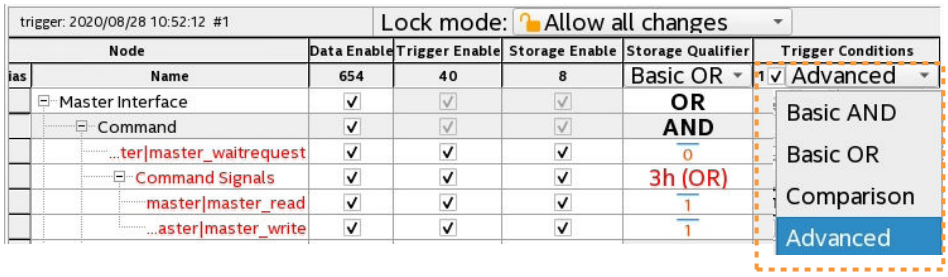


Figure 44. Advanced Trigger Condition Tab

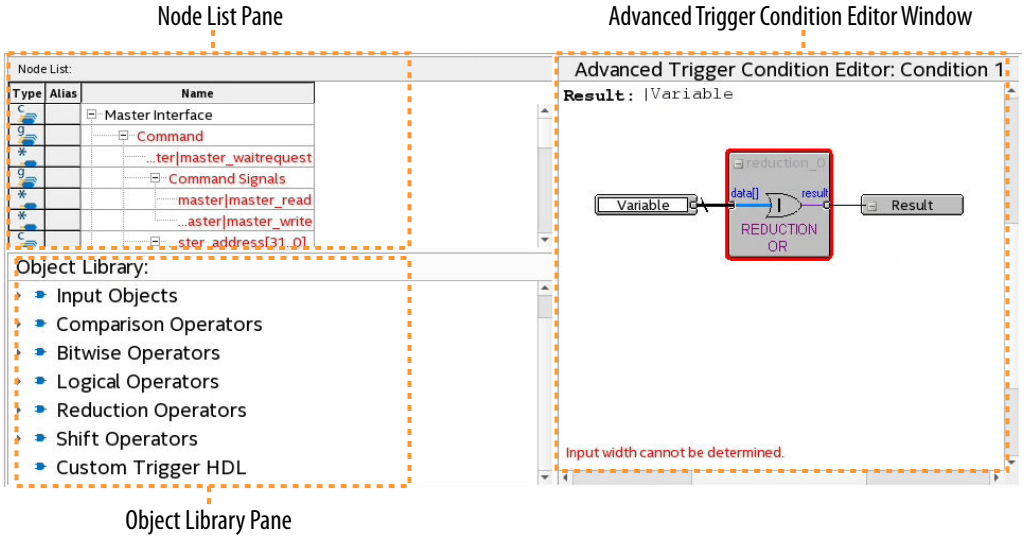

To build a complex trigger condition in an expression tree, drag-and-drop operators from the **Object Library** pane and the **Node List** pane into the **Advanced Trigger Configuration Editor** window.

To configure the operators' settings, double-click or right-click the operators that you placed and click **Properties**.

Table 11. Advanced Triggering Operators

Category	Name
Signal Detection	Edge and Level Detector
Input Objects	Bit Bit Value Bus

continued...

Category	Name
	Bus Value
Comparison	Less Than Less Than or Equal To Equality Inequality Greater Than or Equal To Greater Than
Bitwise	Bitwise Complement Bitwise AND Bitwise OR Bitwise XOR
Logical	Logical NOT Logical AND Logical OR Logical XOR
Reduction	Reduction AND Reduction OR Reduction XOR
Shift	Left Shift Right Shift
Custom Trigger HDL	

Adding many objects to the Advanced Trigger Condition Editor can make the work space cluttered and difficult to read. To keep objects organized while you build your advanced trigger condition, use the shortcut menu and select **Arrange All Objects**. Alternatively, use the **Zoom-Out** command to fit more objects into the **Advanced Trigger Condition Editor** window.

2.4.6.4.1. Examples of Advanced Triggering Expressions

The following examples show how to use advanced triggering:

Figure 45. Bus outa Is Greater Than or Equal to Bus outb

Trigger when bus `outa` is greater than or equal to `outb`.

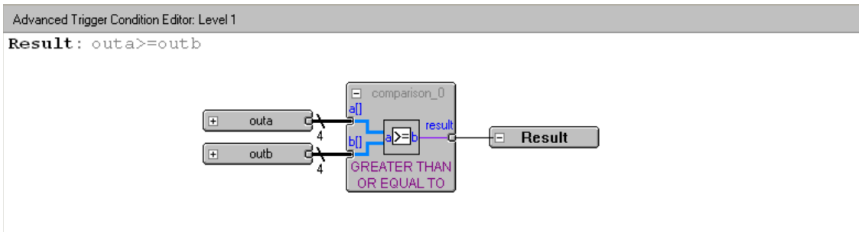

Figure 46. Enable Signal Has a Rising Edge

Trigger when bus `outa` is greater than or equal to bus `outb`, and when the enable signal has a rising edge.

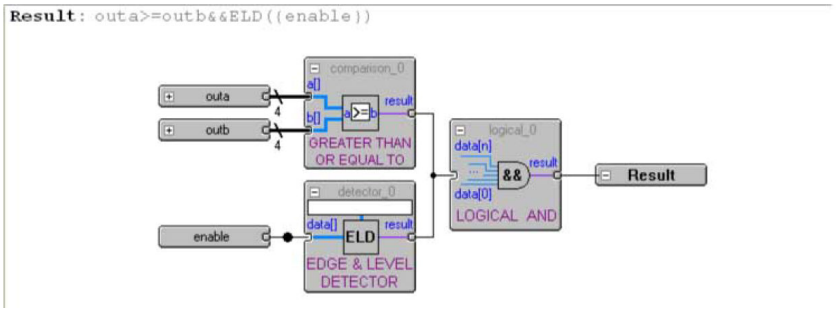

Figure 47. Bitwise AND Operation

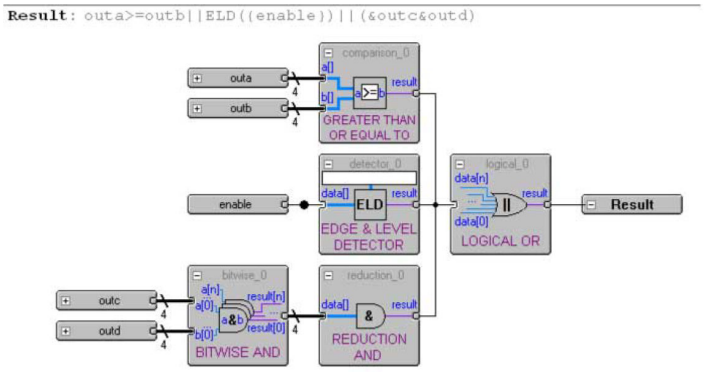
Trigger when bus `outa` is greater than or equal to bus `outb`, or when the enable signal has a rising edge. Or, when a bitwise AND operation has been performed between bus `outc` and bus `outd`, and all bits of the result of that operation are equal to 1.

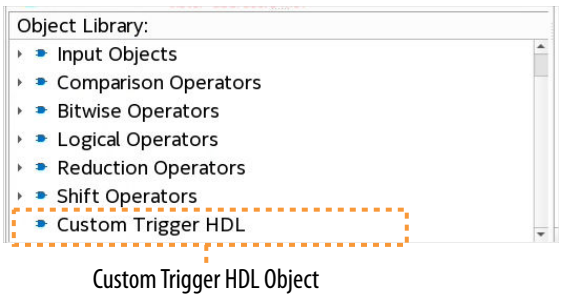


2.4.6.5. Custom Trigger HDL Object

The Signal Tap logic analyzer supports use of your own HDL module to define a custom trigger condition. You can use the Custom Trigger HDL object to simulate your triggering logic and ensure that the logic itself is not faulty. Additionally, you can monitor instances of modules anywhere in the hierarchy of your design, without having to manually route all the necessary connections.

The **Custom Trigger HDL** object appears in the **Object Library** pane of the **Advanced Trigger** editor.

Figure 48. Object Library

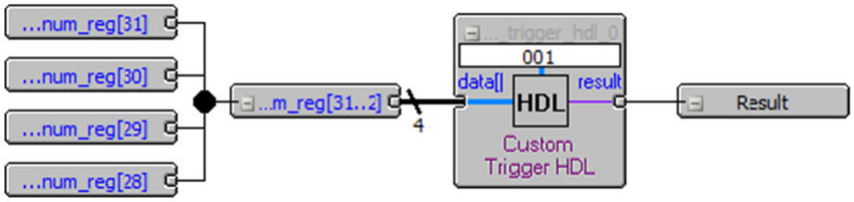


2.4.6.5.1. Using the Custom Trigger HDL Object

To define a custom trigger flow:

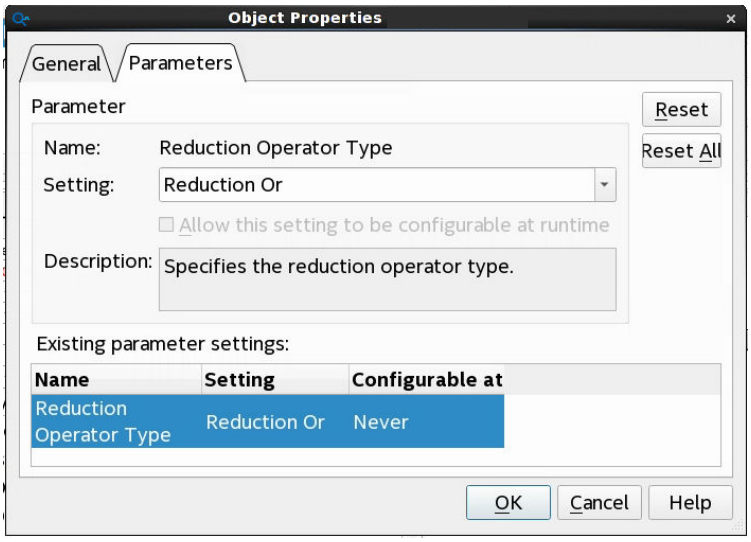
1. Select the trigger you want to edit.
2. Open the **Advanced Trigger** tab by selecting **Advanced** in the **Trigger Conditions** list.
3. Add to your project the Verilog HDL or VHDL source file that contains the trigger module using the **Project Navigator**.
4. Implement the inputs and outputs that your Custom Trigger HDL module requires.
5. Drag in your **Custom Trigger HDL** object and connect the object's data input bus and result output bit to the final trigger result.

Figure 49. Custom Trigger HDL Object



6. Right-click your **Custom Trigger HDL** object and configure the object's properties.

Figure 50. Configure Object Properties



7. Compile your design.
8. Acquire data with Signal Tap using your custom Trigger HDL object.

Example 1. Verilog HDL Triggers

The following trigger uses configuration bitstream:

```
module test_trigger
    (
        input acq_clk, reset,
        input[3:0] data_in,
        input[1:0] pattern_in,
        output reg trigger_out
    );
    always @(pattern_in) begin
        case (pattern_in)
            2'b00:
                trigger_out = &data_in;
            2'b01:
                trigger_out = |data_in;
            2'b10:
                trigger_out = 1'b0;
            2'b11:
                trigger_out = 1'b1;
        endcase
    end
endmodule
```

This trigger does not have configuration bitstream:

```
module test_trigger_no_bs
    (
        input acq_clk, reset,
        input[3:0] data_in,
        output reg trigger_out
    );
    assign trigger_out = &data_in;
endmodule
```

2.4.6.5.2. Required Inputs and Outputs of Custom Trigger HDL Module

Table 12. Custom Trigger HDL Module Required Inputs and Outputs

Name	Description	Input/Output	Required/ Optional
acq_clk	Acquisition clock that Signal Tap uses	Input	Required
reset	Reset that Signal Tap uses when restarting a capture.	Input	Required
data_in	• Data input you connect in the Advanced Trigger editor. • Data your module uses to trigger.	Input	Required
pattern_in	• Module's input for the configuration bitstream property. • Runtime configurable property that you can set from Signal Tap GUI to change the behavior of your trigger logic.	Input	Optional
trigger_out	Output signal of your module that asserts when trigger conditions met.	Output	Required

2.4.6.5.3. Custom Trigger HDL Module Properties

Table 13. Custom Trigger HDL Module Properties

Property	Description
Custom HDL Module Name	Module name of the triggering logic.
Configuration Bitstream	• Allows to create trigger logic that you can configure at runtime, based upon the value of the configuration bitstream. • The Signal Tap logic analyzer reads the configuration bitstream property as binary, therefore the bitstream must contain only the characters `1` and `0`. • The bit-width (number of `1`s and `0`s) must match the `pattern_in` bit width. • A blank configuration bitstream implies that the module does not have a `pattern_in` input.
Pipeline	Specifies the number of pipeline stages in the triggering logic. For example, if after receiving a triggering input the LA needs three clock cycles to assert the trigger output, you can denote a pipeline value of three.

2.4.6.6. Specify Trigger Position

You can specify the amount of data the logic analyzer acquires before and after a trigger event. Positions for Runtime and Power-Up triggers are separate.

The Signal Tap logic analyzer offers three pre-defined ratios of pre-trigger data to post-trigger data:

- **Pre**—saves signal activity that occurred after the trigger (12% pre-trigger, 88% post-trigger).
- **Center**—saves 50% pre-trigger and 50% post-trigger data.
- **Post**—saves signal activity that occurred before the trigger (88% pre-trigger, 12% post-trigger).

These pre-defined ratios apply to both non-segmented buffers and each segment of a buffer.

2.4.6.6.1. Post-fill Count

In a custom state-based triggering flow with the `segment_trigger` and `trigger` buffer control actions, you can use the `post-fill_count` argument to specify a custom trigger position.

- If you do not use the `post-fill_count` argument, the trigger position for the affected buffer defaults to the trigger position you specified in the **Setup** tab.
- In the `trigger` buffer control action (for non-segmented buffers), `post-fill_count` specifies the number of samples to capture before stopping data acquisition.
- In the `segment_trigger` buffer control action (for segmented buffer), `post-fill_count` specifies a data segment.

Note: In the case of `segment_trigger`, acquisition of the current buffer stops immediately if a subsequent triggering action is issued in the next state, regardless of the current buffer's post-fill count. The logic analyzer discards the remaining unfilled post-count acquisitions in the current buffer, and displays them as grayed-out samples in the data window.

When the Signal Tap data window displays the captured data, the trigger position appears as the number of post-count samples from the end of the acquisition segment or buffer.

Sample Number of Trigger Position = (*N* – *Post-Fill Count*)

In this case, *N* is the sample depth of either the acquisition segment or non-segmented buffer.

Related Information

Buffer Control Actions on page 72

2.4.6.7. Power-Up Triggers

Power-Up Triggers capture events that occur during device initialization, immediately after you power or reset the FPGA.

The typical use of Signal Tap logic analyzer is triggering events that occur during normal device operation. You start an analysis manually once the target device fully powers on and the JTAG connection for the device is available. With Signal Tap Power-Up Trigger feature, the Signal Tap logic analyzer captures data immediately after device initialization.

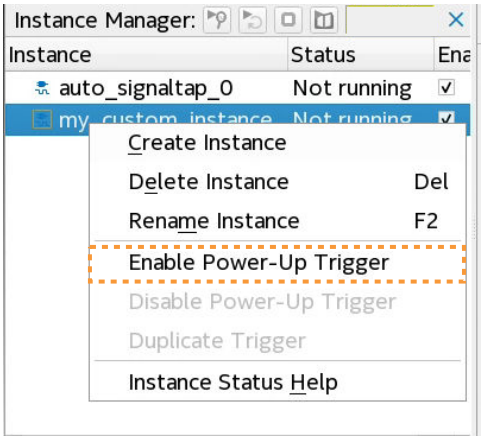
You can add a different Power-Up Trigger to each logic analyzer instance in the **Signal Tap Instance Manager** pane.

2.4.6.7.1. Enabling a Power-Up Trigger

To enable the Power-Up Trigger for Signal Tap instance:

- In the Instance Manager, right-click the Signal Tap instance and click **Enable Power-Up Trigger**.

Figure 51. Enabling Power-Up Trigger in Signal Tap Instance Manager



Power-Up Trigger appears as a child instance of the selected Signal Tap instance. The first time you enable Power-Up Trigger, the **Trigger conditions** column in the **Setup** tab is populated with the default values. Subsequently, when you disable Power-Up Trigger, the current values in the **Setup** tab is retrieved the next time you re-enable Power-Up Trigger.

To disable a Power-Up Trigger, right-click the instance and click **Disable Power-Up Trigger**.

2.4.6.7.2. Configuring Power-Up Trigger Conditions

- Any change that you make to a Power-Up Trigger conditions requires that you recompile the Signal Tap logic analyzer instance, even if a similar change to the Runtime Trigger conditions does not require a recompilation.
- You can also force trigger conditions with the In-System Sources and Probes in conjunction with the Signal Tap logic analyzer. The In-System Sources and Probes feature allows you to drive and sample values on to selected nets over the JTAG chain.

Related Information

Design Debugging Using In-System Sources and Probes on page 145

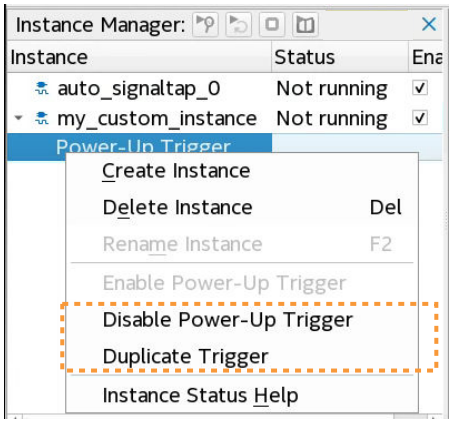
2.4.6.7.3. Managing Signal Tap Instances with Run-Time and Power-Up Trigger Conditions

Inside Instance Manager, on instances that have two types of trigger conditions, Power-Up Trigger conditions are color coded light blue, while Run-Time Trigger conditions remain white.

To switch between the trigger conditions of the Power-Up Trigger and the Run-Time Trigger, double-click the instance name or the Power-Up Trigger name in the **Instance Manager**.

To copy trigger conditions from a Run-Time Trigger to a Power-Up Trigger or vice versa, right-click the trigger name in the **Instance Manager** and click **Duplicate Trigger**. Alternatively, select the trigger name and click **Edit ➤ Duplicate Trigger**.

Figure 52. Instance Manager Commands



Note: Run-time trigger conditions allow fewer adjustments than power-up trigger conditions.

2.4.6.8. External Triggers

External trigger inputs allow you to trigger the Signal Tap logic analyzer from an external source.

The external trigger input behaves like trigger condition 0, in that the condition must evaluate to TRUE before the logic analyzer evaluates any other trigger conditions.

The Signal Tap logic analyzer supplies a signal to trigger external devices or other logic analyzer instances. These features allow you to synchronize external logic analysis equipment with the internal logic analyzer. Power-Up Triggers can use the external triggers feature, but they must use the same source or target signal as their associated Run-Time Trigger.

You can use external triggers to perform cross-triggering on a hard processor system (HPS):

- The processor debugger allows you to configure the HPS to obey or disregard cross-trigger request from the FPGA, and to issue or not issue cross-trigger requests to the FPGA.
- The processor debugger in combination with the Signal Tap external trigger feature allow you to develop a dynamic combination of cross-trigger behaviors.
- You can implement a system-level debugging solution for an Intel FPGA SoC by using the cross-triggering feature with the ARM Development Studio 5 (DS-5) software.

2.4.6.9. Trigger Condition Flow Control

The Trigger Condition Flow Control allows you to define the relationship between a set of triggering conditions. Signal Tap logic analyzer **Signal Configuration** pane offers two flow control mechanisms for organizing trigger conditions:

- **Sequential Triggering**—default triggering flow. Sequential triggering allows you to define up to 10 triggering levels that must be satisfied before the acquisition buffer finishes capturing.
- **State-Based Triggering**—gives the greatest control over your acquisition buffer. Custom-based triggering allows you to organize trigger conditions into states based on a conditional flow that you define.

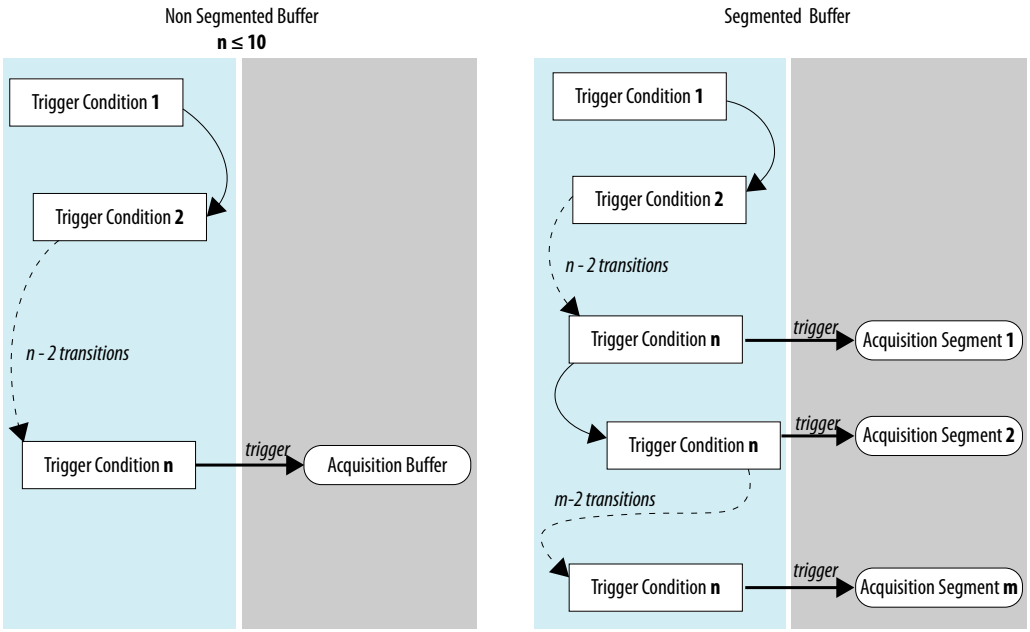
You can use sequential or state based triggering with either a segmented or a non-segmented buffer.

2.4.6.10. Sequential Triggering

When you specify a sequential trigger the Signal Tap logic analyzer sequentially evaluates each the conditions. The sequential triggering flow allows you to cascade up to 10 levels of triggering conditions.

When the last triggering condition evaluates to TRUE, the Signal Tap logic analyzer starts the data acquisition. For segmented buffers, every acquisition segment after the first starts on the last condition that you specified. The Signal Tap **Node** annotates this final condition column with Seg if a segmented buffer is enabled. The Simple Sequential Triggering feature allows you to specify basic triggers, comparison triggers, advanced triggers, or a mix of all three. The following figure illustrates the simple sequential triggering flow for non-segmented and segmented buffers. The acquisition buffer starts capture when all n triggering levels are satisfied, where $n \leq 10$.

Figure 53. Sequential Triggering Flow



The Signal Tap logic analyzer considers external triggers as level 0, evaluating external triggers before any other trigger condition.

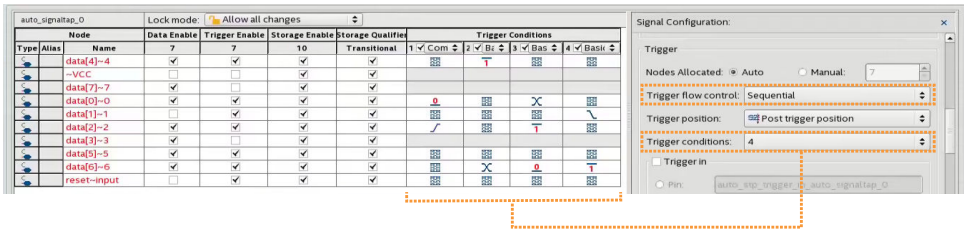
2.4.6.10.1. Configuring the Sequential Triggering Flow

To configure Signal Tap logic analyzer for sequential triggering:

1. On **Trigger Flow Control**, select **Sequential**
2. On **Trigger Conditions**, select the number of trigger conditions from the drop-down list.
   The **Node List** pane now displays the same number of trigger condition columns.
3. Configure each trigger condition in the **Node List** pane.

   You can enable/disable any trigger condition from the column header.

Figure 54. Sequential Triggering Flow Configuration



2.4.6.11. State-Based Triggering

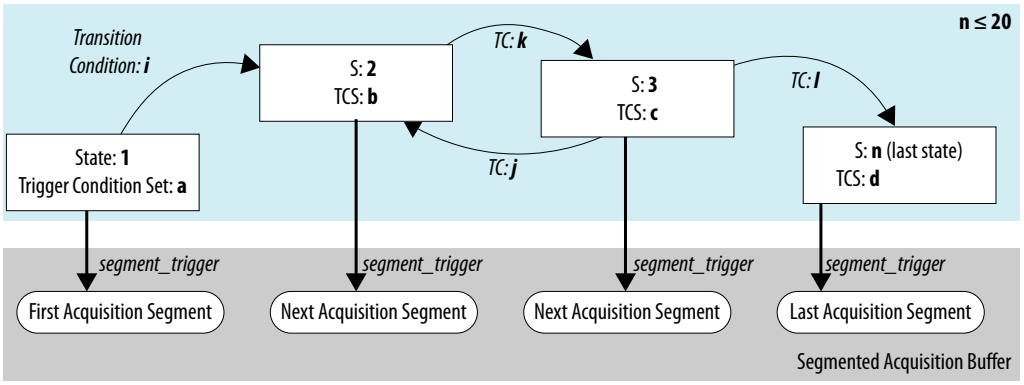
With state-based triggering, a state diagram organizes the events that trigger the acquisition buffer. The states capture all actions that the acquisition buffer performs, and each state contains conditional expressions that define transition conditions.

Custom state-based triggering grants control over triggering condition arrangement. Because the logic analyzer only captures samples of interest, custom state-based triggering allows for more efficient use of the space available in the acquisition buffer.

To help you describe the relationship between triggering conditions, the state-based triggering flow provides tooltips in the GUI. Additionally, you can use the Signal Tap Trigger Flow Description Language, which is based upon conditional expressions.

Each state allows you to define a set of conditional expressions. Conditional expressions are Boolean expressions that depend on a combination of triggering conditions, counters, and status flags. You configure the triggering conditions within the **Setup** tab. The Signal Tap logic analyzer custom-based triggering flow provides counters and status flags.

Figure 55. State-Based Triggering Flow



Within each conditional expression you define a set of actions. Actions include triggering the acquisition buffer to stop capture, a modification to either a counter or status flag, or a state transition.

Trigger actions can apply to either a single segment of a segmented acquisition buffer or to the entire non-segmented acquisition buffer. Each trigger action provides an optional count that specifies the number of samples the buffer captures before the logic analyzer stops acquisition of the current segment. The count argument allows you to control the amount of data the buffer captures before and after a triggering event occurs.

Resource manipulation actions allow you to increment and decrement counters or set and clear status flags. The logic analyzer uses counter and status flag resources as optional inputs in conditional expressions. Counters and status flags are useful for counting the number of occurrences of certain events and for aiding in triggering flow control.

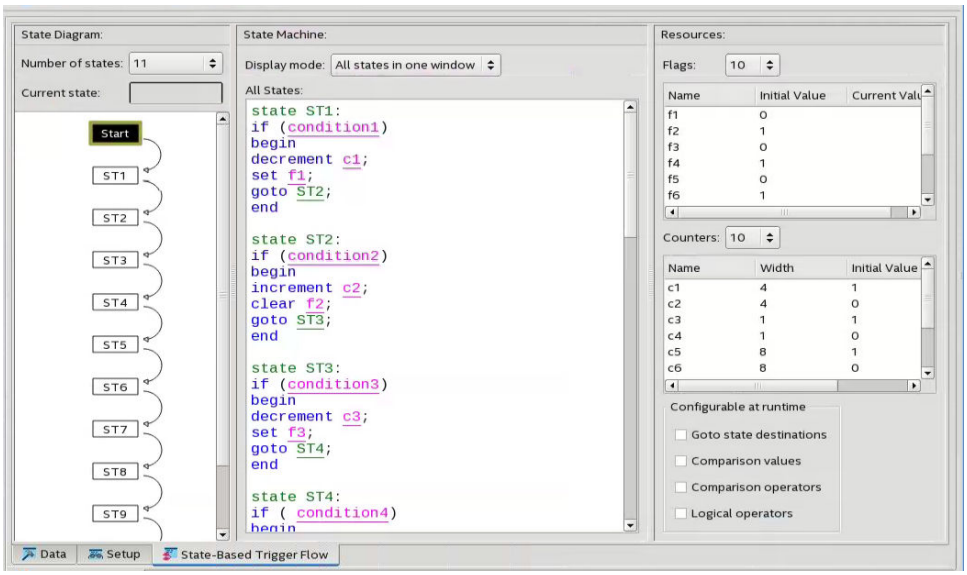
The state-based triggering flow allows you to capture a sequence of events that may not necessarily be contiguous in time. For example, a communication transaction between two devices that includes a hand shaking protocol containing a sequence of acknowledgments.

2.4.6.11.1. State-Based Triggering Flow Tab

The **State-Based Trigger Flow** tab is the control interface for the custom state-based triggering flow.

This tab is only available when you select **State-Based** on the **Trigger Flow Control** list. If you specify **Trigger Flow Control** as **Sequential**, the **State-Based Trigger Flow** tab is not visible.

Figure 56. State-Based Triggering Flow Tab



The **State-Based Trigger Flow** tab contains three panes:

2.4.6.11.2. State Machine Pane

The **State Machine** pane contains the text entry boxes where you define the triggering flow and actions associated with each state.

- You can define the triggering flow using the Signal Tap Trigger Flow Description Language, a simple language based on "if-else" conditional statements.
- Tooltips appear when you move the mouse over the cursor, to guide command entry into the state boxes.
- The GUI provides a syntax check on your flow description in real-time and highlights any errors in the text flow.

The State Machine description text boxes default to show one text box per state. You can also have the entire flow description shown in a single text field. This option can be useful when copying and pasting a flow description from a template or an external text editor. To toggle between one window per state, or all states in one window, select the appropriate option under **State Display mode.**

Related Information

Signal Tap Trigger Flow Description Language on page 68

2.4.6.11.3. Resources Pane

The **Resources** pane allows you to declare status flags and counters for your Custom Triggering Flow's conditional expressions.

- You can increment/decrement counters or set/clear status flags within your triggering flow.
- You can specify up to 20 counters and 20 status flags.
- To initialize counter and status flags, right-click the row in the table and select **Set Initial Value.**
- To specify a counter width, right-click the counter in the table and select **Set Width**.
- To assist in debugging your trigger flow specification, the logic analyzer dynamically updates counters and flag values after acquisition starts.

The **Configurable at runtime** settings allow you to control which options can change at runtime without requiring a recompilation.

Table 14. Runtime Reconfigurable Settings, State-Based Triggering Flow

Setting	Description
Destination of `goto` action	Allows you to modify the destination of the state transition at runtime.
Comparison values	Allows you to modify comparison values in Boolean expressions at runtime. In addition, you can modify the `segment_trigger` and trigger action post-fill count argument at runtime.
Comparison operators	Allows you to modify the operators in Boolean expressions at runtime.
Logical operators	Allows you to modify the logical operators in Boolean expressions at runtime.

2.4.6.11.4. State Diagram Pane

The **State Diagram** pane provides a graphical overview of your triggering flow. this pane displays the number of available states and the state transitions. To adjust the number of available states, use the menu above the graphical overview.

2.4.6.11.5. Signal Tap Trigger Flow Description Language

The Trigger Flow Description Language is based on a list of conditional expressions per state to define a set of actions.

To describe the actions that the logic analyzer evaluates when a state is reached, follow this syntax:

Syntax of Trigger Flow Description Language

```
state <state_label>:
    <action_list>
    if (<boolean_expression>)
        <action_list>
    [else if (<boolean_expression>)
```

```
        <action_list>]
    [else
        <action_list>]
```

- Non-terminals are delimited by "<>".
- Optional arguments are delimited by "[]".
- The priority for evaluation of conditional statements is from top to bottom.
- The Trigger Flow Description Language allows multiple `else if` conditions.

Trigger that Skips Clock Cycles after Hitting Condition on page 71
Storage Qualification with Post-Fill Count Value Less than m on page 72
Resource Manipulation Action on page 72
Buffer Control Actions on page 72
State Transition Action on page 73

Related Information

Custom State-Based Triggering Flow Examples on page 114

<state_label>

Identifies a given state. You use the state label to start describing the actions the logic analyzer evaluates once said state is reached. You can also use the state label with the `goto` command.

The state description header syntax is:
`state` *<state_label>*

The description of a state ends with the beginning of another state or the end of the whole trigger flow description.

<boolean_expression>

Collection of operators and operands that evaluate into a Boolean result. The operators can be logical or relational. Depending on the operator, the operand can reference a trigger condition, a counter and a register, or a numeric value. To group a set of operands within an expression, you use parentheses.

Table 15. Logical Operators

Logical operators accept any boolean expression as an operand.

Operator	Description	Syntax
!	NOT operator	`! expr1`
&&	AND operator	`expr1 && expr2`
||	OR operator	`expr1 || expr2`

Table 16. Relational Operators

You use relational operators on counters or status flags.

Operator	Description	Syntax
>	Greater than	`<identifier> > <numerical_value>`
>=	Greater than or Equal to	`<identifier> >= <numerical_value>`
==	Equals	`<identifier> == <numerical_value>`
!=	Does not equal	`<identifier> != <numerical_value>`
<=	Less than or equal to	`<identifier> <= <numerical_value>`
<	Less than	`<identifier> < <numerical_value>`

Notes to table:
1. *<identifier>* indicates a counter or status flag.
2. *<numerical_value>* indicates an integer.

Note:

- The *<boolean_expression>* in an `if` statement can contain a single event or multiple event conditions.
- When the boolean expression evaluates TRUE, the logic analyzer evaluates all the commands in the *<action_list>* concurrently.

<action_list>

List of actions that the logic analyzer performs within a state once a condition is satisfied.

- Each action must end with a semicolon (`;`).
- If you specify more than one action within an `if` or an `else if` clause, you must delimit the `action_list` with `begin` and `end` tokens.

Possible actions include:

Buffer Control Actions

Actions that control the acquisition buffer.

Table 17. Buffer Control Actions

Action	Description	Syntax
`trigger`	Stops the acquisition for the current buffer and ends analysis. This command is required in every flow definition.	`trigger <post-fill_count>;`
`segment_trigger`	Available only in segmented acquisition mode. Ends acquisition of the current segment. After evaluating this command, the Signal Tap logic analyzer starts acquiring from the next segment. If all segments are written, the logic analyzer overwrites the oldest segment with the latest sample. When a trigger action is evaluated the acquisition stops.	`segment_trigger <post-fill_count>;`

continued...

Action	Description	Syntax
`start_store`	Active only in state-based storage qualifier mode. Asserts the `write_enable` to the Signal Tap acquisition buffer.	`start_store`
`stop_store`	Active only in state-based storage qualifier mode. De-asserts the `write_enable` signal to the Signal Tap acquisition buffer.	`stop_store`

Both `trigger` and `segment_trigger` actions accept an optional `post-fill_count` argument.

State Transition Action

Specifies the next state in the custom state control flow. The syntax is: `goto` *<state_label>*;

Trigger that Skips Clock Cycles after Hitting Condition

Trigger flow description that skips three clock cycles of samples after hitting condition 1

Code:

```
State 1: ST1
    start_store
    if ( condition1 )
    begin
       stop_store;
       goto ST2;
    end
State 2: ST2
    if (c1 < 3)
       increment c1; //skip three clock cycles; c1 initialized to 0
    else if (c1 == 3)
    begin
       start_store;//start_store necessary to enable writing to finish
                   //acquisition
       trigger;
    end
```

The figures show the data transaction on a continuous capture and the data capture when you apply the Trigger flow description.

Figure 57. Continuous Capture of Data Transaction

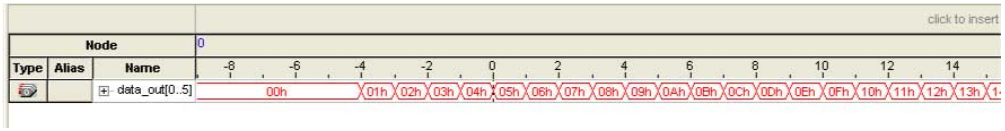

Figure 58. Capture of Data Transaction with Trigger Flow Description Applied

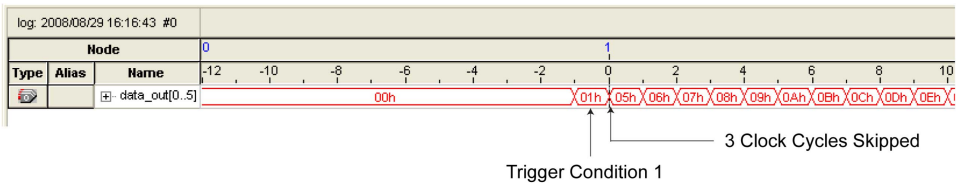
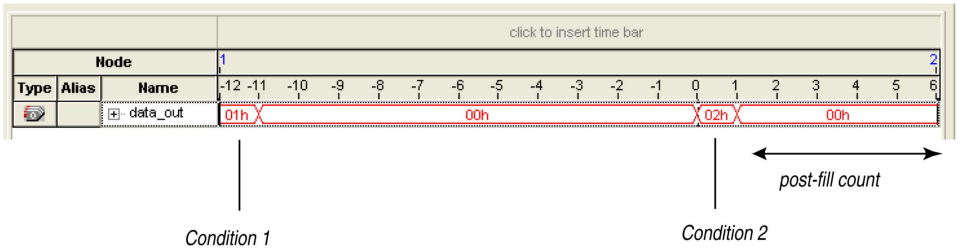


Storage Qualification with Post-Fill Count Value Less than m

The data capture finishes successfully. It uses a buffer with a sample depth of 64, *m* = *n* = *10*, and `post-fill count = 5`.

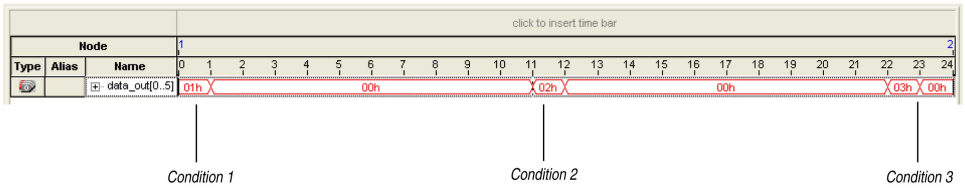
Real data acquisition of the previous scenario

Figure 59. Storage Qualification with Post-Fill Count Value Less than m (Acquisition Successfully Completes)



The combination of using counters, Boolean and relational operators in conjunction with the `start_store` and `stop_store` commands can give a clock-cycle level of resolution to controlling the samples that are written into the acquisition buffer.

Figure 60. Waveform After Forcing the Analysis to Stop



Resource Manipulation Action

The resources the trigger flow description uses can be either counters or status flags.

Table 18. Resource Manipulation Actions

Action	Description	Syntax
`increment`	Increments a counter resource by 1	`increment <counter_identifier>;`
`decrement`	Decrements a counter resource by 1	`decrement <counter_identifier>;`
`reset`	Resets counter resource to initial value	`reset <counter_identifier>;`
`set`	Sets a status flag to 1	`set <register_flag_identifier>;`
`clear`	Sets a status flag to 0	`clear <register_flag_identifier>;`

Buffer Control Actions

Actions that control the acquisition buffer.

Table 19. Buffer Control Actions

Action	Description	Syntax
`trigger`	Stops the acquisition for the current buffer and ends analysis. This command is required in every flow definition.	`trigger <post-fill_count>;`
`segment_trigger`	Available only in segmented acquisition mode. Ends acquisition of the current segment. After evaluating this command, the Signal Tap logic analyzer starts acquiring from the next segment. If all segments are written, the logic analyzer overwrites the oldest segment with the latest sample. When a trigger action is evaluated the acquisition stops.	`segment_trigger <post-fill_count>;`
`start_store`	Active only in state-based storage qualifier mode. Asserts the `write_enable` to the Signal Tap acquisition buffer.	`start_store`
`stop_store`	Active only in state-based storage qualifier mode. De-asserts the `write_enable` signal to the Signal Tap acquisition buffer.	`stop_store`

Both `trigger` and `segment_trigger` actions accept an optional `post-fill_count` argument.

Related Information

Post-fill Count on page 61

State Transition Action

Specifies the next state in the custom state control flow. The syntax is:
`goto` *<state_label>*;

2.4.6.11.6. State-Based Storage Qualifier Feature

Selecting a state-based storage qualifier type enables the `start_store` and `stop_store` actions. When you use these actions in conjunction with the expressions of the State-based trigger flow, you get maximum flexibility to control data written into the acquisition buffer.

Note: You can only apply the `start_store` and `stop_store` commands to a non-segmented buffer.

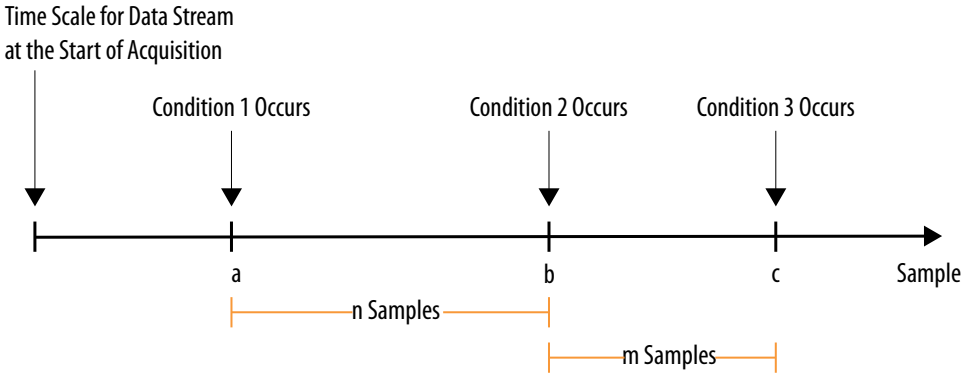
The `start_store` and `stop_store` commands are similar to the start and stop conditions of the **start/stop** storage qualifier mode. If you enable storage qualification, the Signal Tap logic analyzer doesn't write data into the acquisition buffer until the `start_store` command occurs. However, in the state-based storage qualifier type you must include a `trigger` command as part of the trigger flow description. This `trigger` command is necessary to complete the acquisition and display the results on the waveform display.

Storage Qualification Feature for the State-Based Trigger Flow

This trigger flow description contains three trigger conditions that occur at different times after you click **Start Analysis**:

```
State 1: ST1:
    if ( condition1 )
       start_store;
    else if ( condition2 )
       trigger value;
    else if ( condition3 )
       stop_store;
```

Figure 61. Capture Scenario for Storage Qualification with the State-Based Trigger Flow



When you apply the trigger flow to the scenario in the figure:

1. The Signal Tap logic analyzer does not write into the acquisition buffer until **Condition 1** occurs (sample **a**).
2. When **Condition 2** occurs (sample **b**), the logic analyzer evaluates the `trigger value` command, and continues to write into the buffer to finish the acquisition.
3. The trigger flow specifies a `stop_store` command at sample **c**, which occurs `m` samples after the trigger point.
4. If the data acquisition finishes the post-fill acquisition samples before **Condition 3** occurs, the logic analyzer finishes the acquisition and displays the contents of the waveform. In this case, the capture ends if the post-fill count value is < `m`.
5. If the post-fill count value in the Trigger Flow description 1 is > `m` samples, the buffer pauses acquisition indefinitely, provided there is no recurrence of Condition 1 to trigger the logic analyzer to start capturing data again.

The Signal Tap logic analyzer continues to evaluate the `stop_store` and `start_store` commands even after evaluating the trigger. If the acquisition paused, click **Stop Analysis** to manually stop and force the acquisition to trigger. You can use counter values, flags, and the State diagram to help you perform the trigger flow. The counter values, flags, and the current state update in real-time during a data acquisition.

2.4.6.12. Trigger Lock Mode

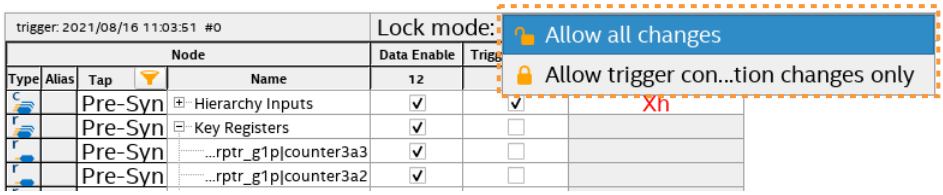
Trigger lock mode restricts changes to only the configuration settings that you specify as **Configurable at runtime**. The runtime configurable settings for the **Custom Trigger Flow** tab are on by default.

Note: You may get some performance advantages by disabling some of the runtime configurable options.

You can restrict changes to your Signal Tap configuration to include only the options that do not require a recompilation. Trigger lock-mode allows you to make changes that reflect immediately in the device.

1. On the **Setup** tab, point to **Lock mode** and select **Allow trigger condition changes only**.

Figure 62. Allow Trigger Conditions Change Only



2. Modify the Trigger Flow conditions.

2.4.7. Specifying Pipeline Settings

The **Pipeline factor** setting indicates the number of pipeline registers that the Intel Quartus Prime software can add to boost the f_{MAX} of the Signal Tap logic analyzer.

To specify the pipeline factor from the Signal Tap GUI:

- In the **Signal Configuration** pane, specify a **pipeline factor** ranging from 0 to 5. The default value is 0.

Note: Setting the pipeline factor does not guarantee an increase in f_{MAX}, as the pipeline registers may not be in the critical paths.

Alternatively, you can specify pipeline parameters as part of HDL instantiation, as Creating a Signal Tap Instance by HDL Instantiation on page 35 describes.

Note: The Signal Tap Intel FPGA IP is not optimized for the Intel Hyperflex architecture.

2.4.8. Filtering Relevant Samples

The Storage Qualifier feature allows you to filter out individual samples not relevant to debugging your design.

The Signal Tap logic analyzer offers a snapshot in time of the data that the acquisition buffers store. By default, the Signal Tap logic analyzer writes into acquisition memory with data samples on every clock cycle. With a non-segmented buffer, there is one data window that represents a comprehensive snapshot of the data stream. Conversely, segmented buffers use several smaller sampling windows spread out over more time, with each sampling window representing a contiguous data set.

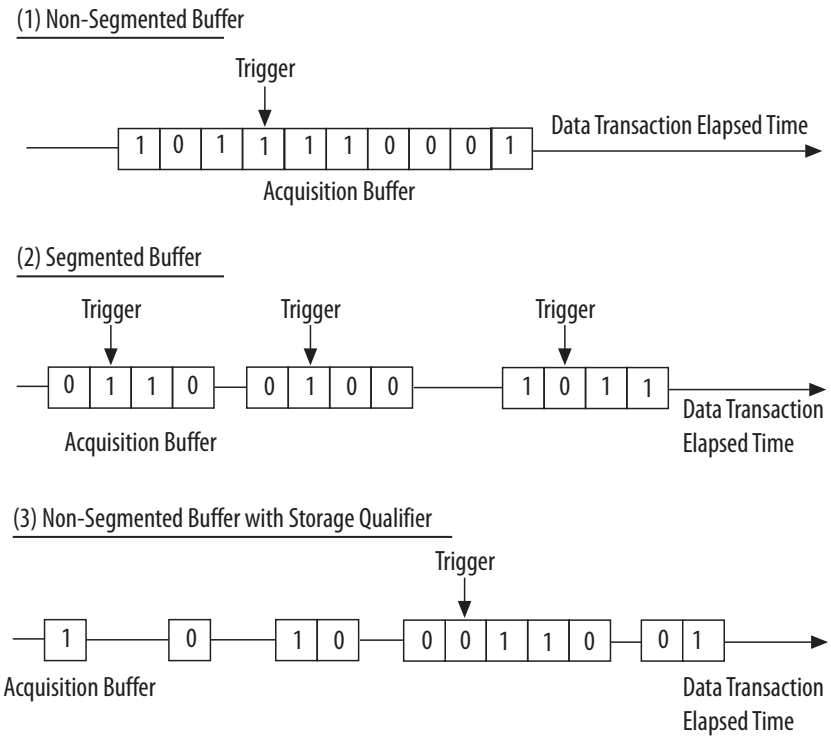
With analysis using acquisition buffers you can capture most functional errors in a chosen signal set, provided adequate trigger conditions and a generous sample depth for the acquisition. However, each data window can have a considerable amount of unnecessary data; for example, long periods of idle signals between data bursts. The default behavior in the Signal Tap logic analyzer doesn't discard the redundant sample bits.

The Storage Qualifier feature allows you to establish a condition that acts as a write enable to the buffer during each clock cycle of data acquisition, thus allowing a more efficient use of acquisition memory over a longer period of analysis.

Because you can create a discontinuity between any two samples in the buffer, the Storage Qualifier feature is equivalent to creating a custom segmented buffer in which the number and size of segment boundaries are adjustable.

Note: You can only use the Storage Qualifier feature with a non-segmented buffer. The IP Catalog flow only supports the Input Port mode for the Storage Qualifier feature.

Figure 63. Data Acquisition Using Different Modes of Controlling the Acquisition Buffer



Notes to figure:

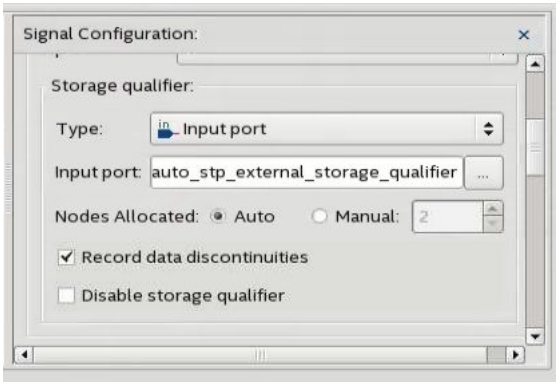
1. Non-segmented buffers capture a fixed sample window of contiguous data.
2. Segmented buffers divide the buffer into fixed sized segments, with each segment having an equal sample depth.
3. Storage Qualifier allows you to define a custom sampling window for each segment you create with a qualifying condition, thus potentially allowing a larger time scale of coverage.

There are six storage qualifier types available under the Storage Qualifier feature:

- **Continuous** (default) Turns the Storage Qualifier off.
- **Input port**
- **Transitional**

- **Conditional**
- **Start/Stop**
- **State-based**

Figure 64. Storage Qualifier Settings



Upon the start of an acquisition, the Signal Tap logic analyzer examines each clock cycle and writes the data into the buffer based upon the storage qualifier type and condition. Acquisition stops when a defined set of trigger conditions occur.

The Signal Tap logic analyzer evaluates trigger conditions independently of storage qualifier conditions.

2.4.8.1. Input Port Mode

When using the Input port mode, the Signal Tap logic analyzer takes any signal from your design as an input. During acquisition, if the signal is high on the clock edge, the Signal Tap logic analyzer stores the data in the buffer. If the signal is low on the clock edge, the logic analyzer ignores the data sample. If you don't specify an internal node, the logic analyzer creates and connects a pin to this input port.

When creating a Signal Tap logic analyzer instance with the Signal Tap logic analyzer GUI, specify the **Storage Qualifier** signal for the **Input port** field located on the **Setup** tab. You must specify this port for your project to compile.

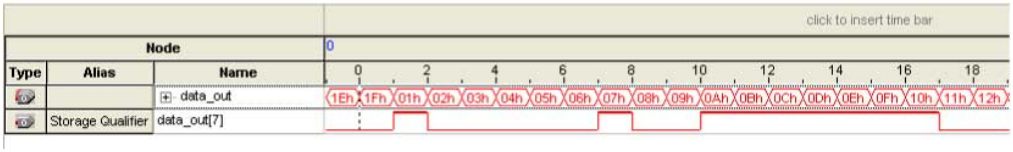
When creating a Signal Tap logic analyzer instance through HDL instantiation, specify the **Storage Qualifier** parameter to include in the instantiation template. You can then connect this port to a signal in your RTL. If you enable the input port storage qualifier, the port accepts a signal and predicates when signals are recorded into the acquisition buffer before or after the specified trigger condition occurs. That is, the trigger you specify is responsible for triggering and moving the logic analyzer into the post-fill state. The input port storage qualifier signal you select controls the recording of samples.

The following example compares and contrasts two waveforms of the same data, one without storage qualifier enabled (**Continuous** means always record samples, effectively no storage qualifier), and the other with **Input Port** mode. The bottom signal in the waveform, `data_out[7]`,is the input port storage qualifier signal. The continuous mode waveform shows 01h, 07h, 0Ah, 0Bh, 0Ch, 0Dh, 0Eh, 0Fh, 10h as the sequence of `data_out[7]` bus values where the storage qualifier signal is asserted. The lower waveform for input port storage qualifier shows how this same

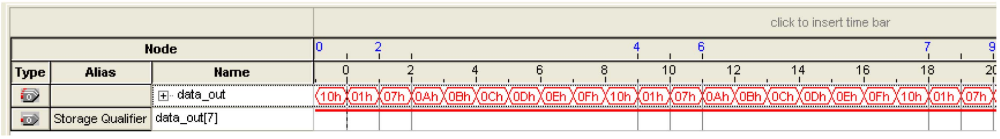
traffic pattern of the `data_out` bus is recorded when you enable the input port storage qualifier. Values recorded are a repeating sequence of the 01h, 07h, 0Ah, 0Bh, 0Ch, 0Dh, 0Eh, 0Fh, 10h (same as **Continuous** mode).

Figure 65. Comparing Continuous and Input Port Capture Mode in Data Acquisition of a Recurring Data Pattern

- **Continuous** Mode:



- **Input Port** Storage Qualifier:



2.4.8.2. Transitional Mode

In **Transitional** mode, the logic analyzer monitors changes in a set of signals, and writes new data in the acquisition buffer only after detecting a change. You select the signals for monitoring using the check boxes in the **Storage Qualifier** column.

Figure 66. Transitional Storage Qualifier Setup

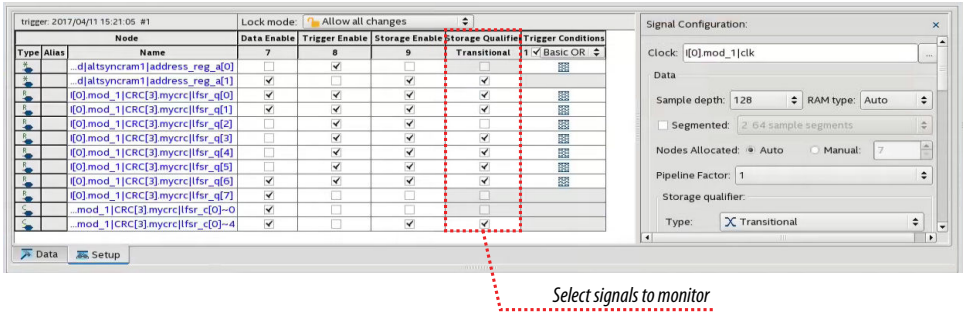


Figure 67. Comparing Continuous and Transitional Capture Mode in Data Acquisition of a Recurring Data Pattern

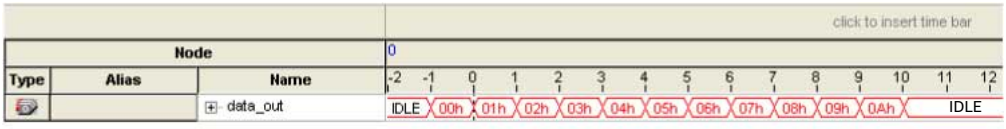
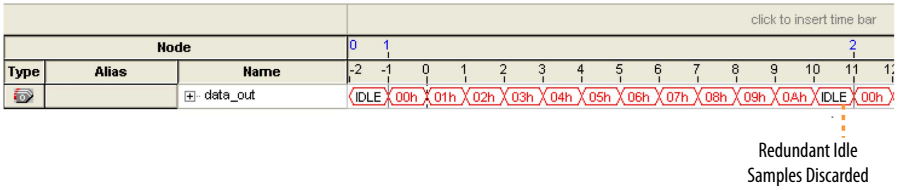
- **Continuous** mode:



- **Transitional** mode:



2.4.8.3. Conditional Mode

In **Conditional** mode, the Signal Tap logic analyzer determines whether to store a sample by evaluating a combinational function of predefined signals within the node list. The Signal Tap logic analyzer writes into the buffer during the clock cycles in which the condition you specify evaluates TRUE.

You can select either **Basic AND**, **Basic OR**, **Comparison**, or **Advanced** storage qualifier conditions. A **Basic AND** or **Basic OR** condition matches each signal to one of the following:

- **Don't Care**
- **Low**
- **High**
- **Falling Edge**
- **Rising Edge**
- **Either Edge**

If you specify a **Basic AND** storage qualifier condition for more than one signal, the Signal Tap logic analyzer evaluates the logical AND of the conditions.

You can specify any other combinational or relational operators with the enabled signal set for storage qualification through advanced storage conditions.

You can define storage qualification conditions similar to the manner in which you define trigger conditions.

Figure 68. Conditional Storage Qualifier Setup

The figure details the conditional storage qualifier setup in the `.stp` file.

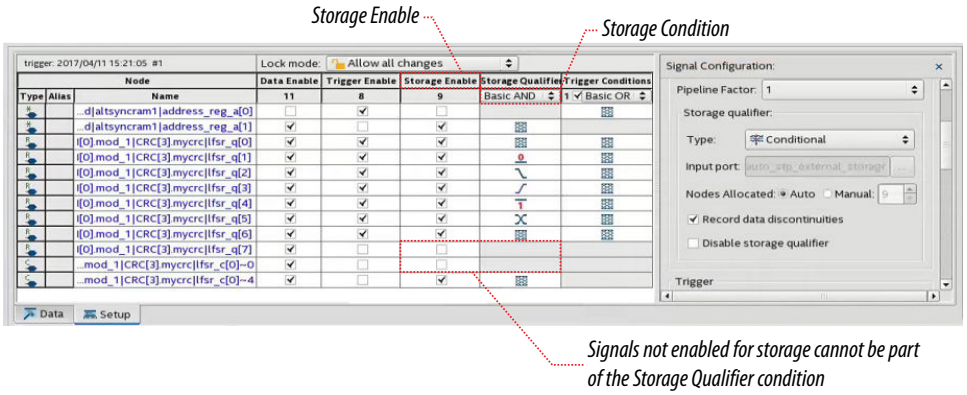


Figure 69. Comparing Continuous and Conditional Capture Mode in Data Acquisition of a Recurring Data Pattern

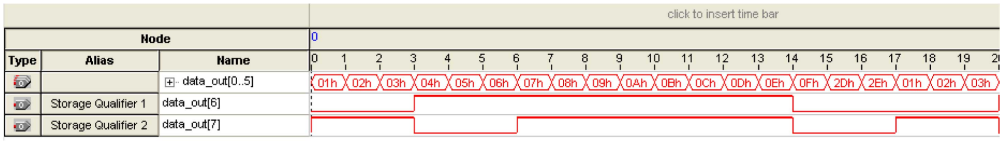
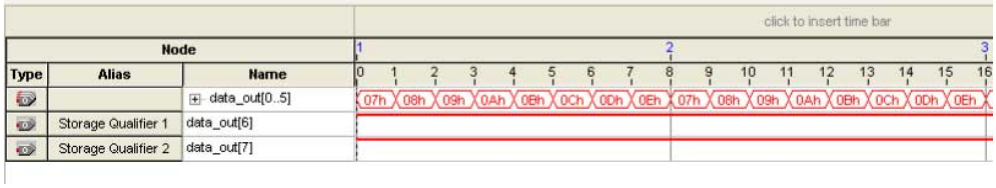
The data pattern is the same in both cases.

- **Continuous** sampling capture mode:



- **Conditional** sampling capture mode:



Related Information

- Basic Trigger Conditions on page 52
- Comparison Trigger Conditions on page 54
- Advanced Trigger Conditions on page 56

2.4.8.4. Start/Stop Mode

The **Start/Stop** mode uses two sets of conditions, one to start data capture and one to stop data capture. If the start condition evaluates to TRUE, the Signal Tap logic analyzer stores the buffer data every clock cycle until the stop condition evaluates to TRUE, which then pauses the data capture. The logic analyzer ignores additional start signals received after the data capture starts. If both start and stop evaluate to TRUE at the same time, the logic analyzer captures a single cycle.

Note: You can force a trigger by pressing the **Stop** button if the buffer fails to fill to completion due to a stop condition or if the start condition never occurs.

Figure 70. Start/Stop Mode Storage Qualifier Setup

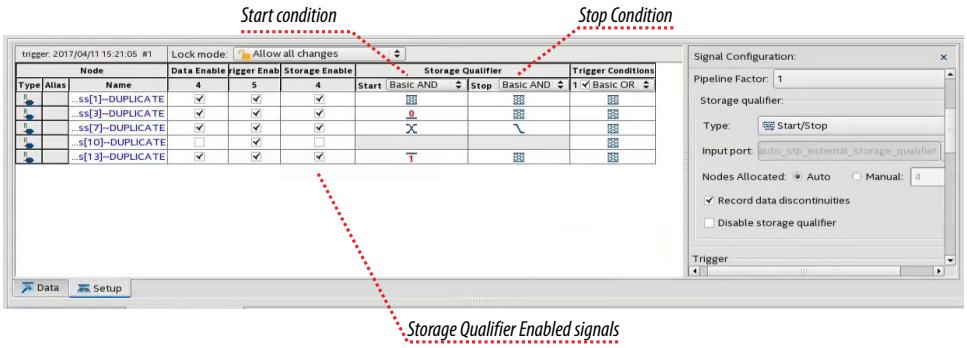


Figure 71. Comparing Continuous and Start/Stop Acquisition Modes for a Recurring Data Pattern

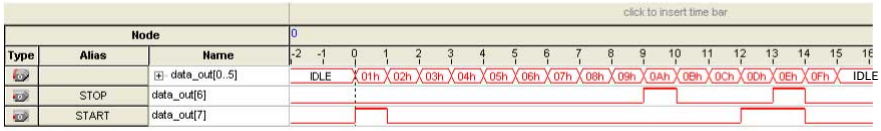
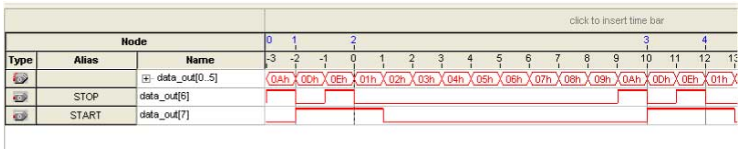
- **Continuous** Mode:



- **Start/Stop** Storage Qualifier:



2.4.8.5. State-Based Mode

The State-based storage qualification mode is part of the State-based triggering flow. The state based triggering flow evaluates a conditional language to define how the Signal Tap logic analyzer writes data into the buffer. With the State-based trigger flow, you have command over boolean and relational operators to guide the execution flow for the target acquisition buffer.

When you enable the storage qualifier feature for the State-based flow, two additional commands become available: `start_store` and `stop_store`. These commands are similar to the Start/Stop capture conditions. Upon the start of acquisition, the Signal Tap logic analyzer doesn't write data into the buffer until a `start_store` action is performed. The `stop_store` command pauses the acquisition. If both `start_store` and `stop_store` actions occur within the same clock cycle, the logic analyzer stores a single sample into the acquisition buffer.

Related Information

State-Based Triggering on page 65

2.4.8.6. Showing Data Discontinuities

When you turn on **Record data discontinuities**, the Signal Tap logic analyzer marks the samples during which the acquisition paused from a storage qualifier. This marker is displayed in the waveform viewer after acquisition completes.

2.4.8.7. Disable the Storage Qualifier

You can disable the storage qualifier with the **Disable Storage Qualifier** option, and then perform a continuous capture. The **Disable Storage Qualifier** option is run-time reconfigurable. Changing the storage qualifier mode from the **Type** field requires recompilation of the project.

2.5. Step 3: Compile the Design and Signal Tap Instances

After you configure one or more Signal Tap instances and define trigger conditions, you must compile your project that includes the Signal Tap logic analyzer, prior to device configuration.

When you define a Signal Tap instance in the logic analyzer GUI or with HDL instantiation, the Signal Tap logic analyzer instance becomes part of your design for compilation.

To run full compilation of the design that includes the Signal Tap logic analyzer instance:

- Click **Processing ➤ Start Compilation**

You can employ various techniques to preserve specific signals for debugging during compilation, and to reduce overall compilation time and iterations. Refer to the following sections for more details.

2.5.1. Recompiling Only Signal Tap Changes

Certain Signal Tap configuration changes require a full recompilation of the design to implement. However, you can use the **Start Recompile** command to implement the following types of configuration changes without running a full design compilation.

Table 20. Signal Tap Configuration Changes Not Requiring Full Compilation

Change the post-fit tap target	Increase the number of post-fit targets
Change the post-fit tap inputs to a Basic AND trigger	Change the post-fit tap inputs to a Basic OR trigger
Change an Advanced trigger (post-fit inputs or logic)	Convert a pre-synthesis tap into a post-fit tap

Start Recompile appends Signal Tap node changes to the existing finalized snapshot, without changing placement and routing outside of the Signal Tap partition.

To recompile Signal Tap configuration changes only, follow these steps:

1. Make supported changes to the Signal Tap configuration in the **Signal Configuration** pane, according to Signal Tap Configuration Changes Not Requiring Full Compilation.
2. In the Signal Tap window, click **Processing ➤ Start Recompile**, or click the **Start Recompile** button. A dialog box displays whether each change is Supported or Unsupported by **Start Recompile**.

Figure 72. Signal Tap Toolbar Start Recompile Button and Command

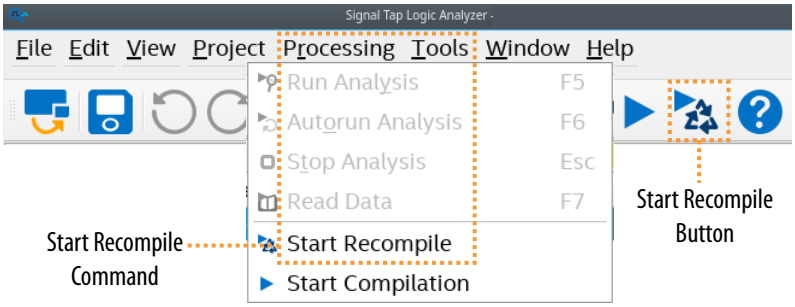


Figure 73. Recompilation Changes List

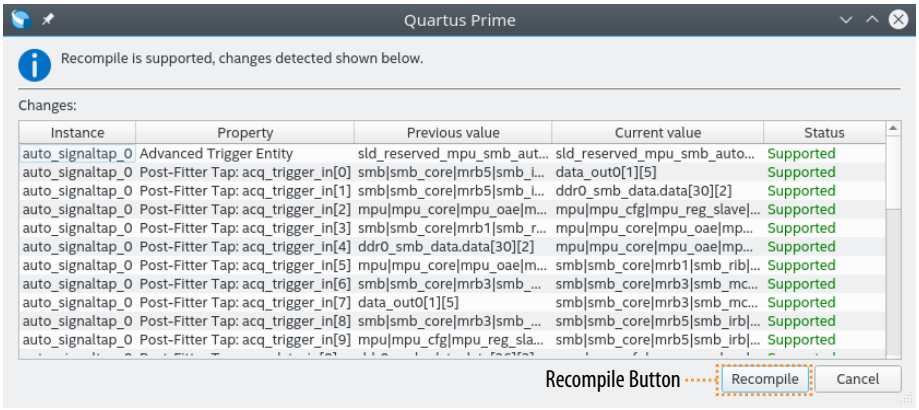

3. If the Signal Tap configuration changes have a **Status** of Supported, click the **Recompile** button to recompile and implement only the Signal Tap configuration changes, as Recompilation Changes List shows.
4. For any change with **Status** of Unsupported, you must either revert the change to **Previous value**, or click **Processing ➤ Start Compilation** in Signal Tap to perform a full compilation to implement the change.

Figure 74. Signal Tap Toolbar Start Compilation Button and Command

Changing the Post-Fit Target Nodes on page 86

2.5.2. Timing Preservation

The following techniques can help you preserve timing in designs that include the Signal Tap logic analyzer:

- Avoid adding critical path signals to the `.stp` file.
- Minimize the number of combinational signals you add to the `.stp` file, and add registers whenever possible.
- Specify an f_{MAX} constraint for each clock in the design.

Related Information

Timing Closure and Optimization
In *Intel Quartus Prime Pro Edition User Guide: Design Optimization*

2.5.3. Performance and Resource Considerations

When you perform logic analysis of your design, you can see the necessary trade-off between runtime flexibility, timing performance, and resource usage. The Signal Tap logic analyzer allows you to select runtime configurable parameters to balance the need for runtime flexibility, speed, and area.

The default values of the runtime configurable parameters provide maximum flexibility, so you can complete debugging as quickly as possible; however, you can adjust these settings to determine whether there is a more appropriate configuration for your design. Because performance results are design-dependent, try these options in different combinations until you achieve the desired balance between functionality, performance, and utilization.

2.5.3.1. Increasing Signal Tap Logic Performance

If Signal Tap logic is part of your critical path, follow these tips to speed up the performance of the Signal Tap logic:

- **Disable runtime configurable options**—runtime flexibility features expend some device resources. If you use Advanced Triggers or State-based triggering flow, disable runtime configurable parameters to a boost in f_{MAX} of the Signal Tap logic. If you use the State-based triggering flow, disable the **Goto state destination** option and perform a recompilation before disabling the other runtime configurable options. The **Goto state destination** option has the greatest impact on f_{MAX}, compared to the other runtime configurable options.
- **Minimize the number of signals that have Trigger Enable selected**—By default, the Signal Tap logic analyzer enables the **Trigger Enable** option for all signals that you add to the `.stp` file. For signals that you do not plan to use as triggers, turn this option off.
- **Turn on Physical Synthesis for register retiming**—If many (more than the number of inputs that fit in a LAB) enabled triggering signals fan-in logic to a gate-based triggering condition (basic trigger condition or a logical reduction operator in the advanced trigger tab), turn on **Perform register retiming**. This can help balance combinational logic across LABs.

2.5.3.2. Reducing Signal Tap Device Resources

If your design has resource constraints, follow these tips to reduce the logic or memory the Signal Tap logic analyzer requires:

- **Disable runtime configurable options**—disabling runtime configurability for advanced trigger conditions or runtime configurable options in the State-based triggering flow results in fewer LEs.
- **Minimize the number of segments in the acquisition buffer**—you can reduce the logic resources that the Signal Tap logic analyzer requires if you limit the segments in your sampling buffer.
- **Disable the Data Enable for signals that you use only for triggering**—by default, the Signal Tap logic analyzer enables **data enable** options for all signals. Turning off the **data enable** option for signals you use only as trigger inputs saves memory resources.

2.6. Step 4: Program the Target Hardware

After you add the Signal Tap logic analyzer instance to your project and fully compile the design, you configure the FPGA target device with your design that includes the Signal Tap logic analyzer instance. You can also program multiple devices with different designs and simultaneously debug them.

When you debug a design with the Signal Tap logic analyzer, you can program a target device directly using the supported JTAG hardware from the Signal Tap window, without using the Intel Quartus Prime Programmer.

Related Information

- Managing Multiple Signal Tap Configurations on page 101
- Intel Quartus Prime Pro Edition User Guide: Programmer

2.6.1. Ensure Compatibility Between .stp and .sof Files

The `.stp` file is compatible with a `.sof` file if the logic analyzer instance parameters, such as the size of the capture buffer and the monitoring and triggering signals, match the programming settings for the target device.

If the files are not compatible, you can still program the device, but you cannot run or control the logic analyzer from the Signal Tap logic analyzer GUI.

Use either of the following methods to ensure compatibility between `.stp` and `.sof` files

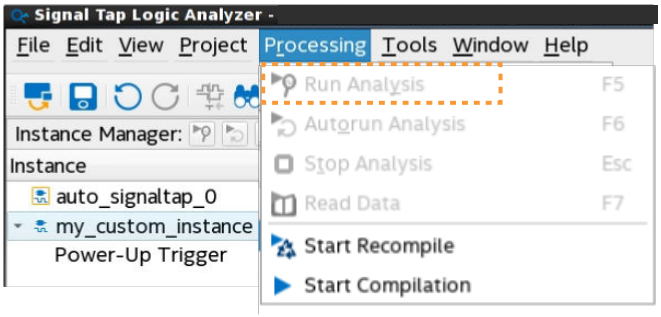
- Attach the .sof file to the .stp file in the SOF Manager. The SOF Manager ensures compatibility between any attached `.sof` files and the current `.stp` file settings automatically, as SOF Manager on page 102 describes.
- To ensure programming compatibility, program the FPGA device with the most recent `.sof` file.

Note: When the Signal Tap logic analyzer detects incompatibility after the analysis starts, the Intel Quartus Prime software generates a system error message containing two CRC values: the expected value and the value retrieved from the `.stp` instance on the device. The CRC value comes from all Signal Tap settings that affect the compilation.

2.7. Step 5: Run the Signal Tap Logic Analyzer

Debugging signals with the Signal Tap logic analyzer GUI is similar to debugging with an external logic analyzer. During normal device operation, you control the logic analyzer through the JTAG connection, specifying the start time for trigger conditions to begin capturing data.

Figure 75. Starting Signal Tap Analysis



1. Select the Signal Tap instance, and then initialize the logic analyzer for that instance by clicking **Processing ➤ Run Analysis** in the Signal Tap logic analyzer GUI.
2. When a trigger event occurs, the logic analyzer stores the captured data in the FPGA device's memory buffer, and then transfers this data to the **Signal Configuration** pane **Data** tab. You can perform the equivalent of a force trigger instruction that allows you to view the captured data currently in the buffer without a trigger event occurring.

You can also use In-System Sources and Probes in conjunction with the Signal Tap logic analyzer to force trigger conditions. The In-System Sources and Probes feature allows you to drive and sample values on to selected signals over the JTAG chain.

2.7.1. Changing the Post-Fit Signal Tap Target Nodes

After performing full compilation of your design and Signal Tap instance, you can subsequently make iterative changes to the post-fit Signal Tap nodes that you want to target, without rerunning full compilation to implement the changes.

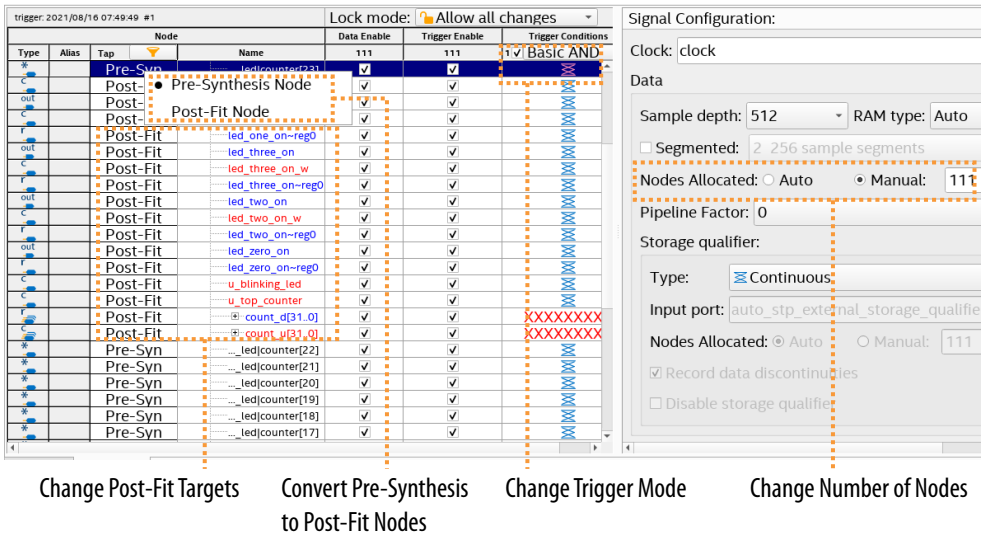
The Signal Tap **Node** list displays whether a target node is **Pre-Syn** (pre-synthesis) or **Post-Fit** in the filterable **Tap** column.

To modify the post-fit Signal Tap nodes:

1. Optionally, mark signals for debug, as Preserving Signals for Monitoring and Debugging describes.

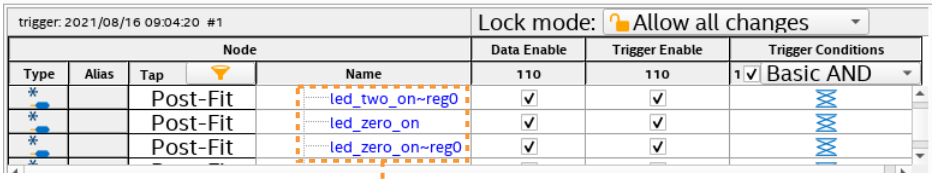
   Note: You cannot change all pre-synthesis nodes to post-fit nodes, unless you are changing the nodes before running full compilation. Once you preserve any signal with `preserve_for_debug`, you can change those preserved pre-synthesis nodes to post-fit nodes.
2. In the **Signal Configuration** pane, modify any of the following properties for nodes with a **Tap** of **Post-Fit**:

Figure 76. Changing the Post-Fit Signal Tap Nodes



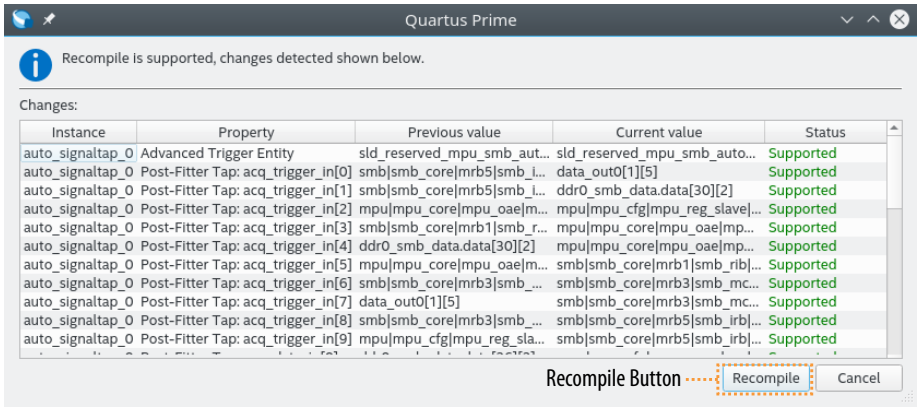
- In the **Name** column, modify or add a new post-fit Signal Tap node target, regardless of the trigger mode.
- In the **Trigger Conditions** column, modify the trigger mode. You can add the post-fit Signal Tap node inputs to a **Basic AND** or **Basic OR** trigger.
- In **Nodes Allocated**, you can specify the **Manual** option to increase or decrease the number of post-fit node targets. You can use manual allocation to help you avoid any major logic change that may require a full recompilation. The data input width affects memory use. The trigger input and storage input width affects the complexity of the condition logic, which can increase the device resource use and the complexity of timing closure.
- Right-click any pre-synthesis Signal Tap node to convert to a post-fit Signal Tap node. The conversion is only successful if Signal Tap can resolve pre-synthesis to post-fit name mapping. Otherwise, the node appears in red and connected to ground. When conversion is successful the post-fit taps names appear in blue text.

Figure 77. Post-fit Taps Names Appear in Blue Text



3. After your post-fit node changes are complete, click **Processing ➤ Start Recompile** to implement only the Signal Tap node changes. A dialog box appears that lists the changes you are implementing, and whether recompilation supports the change.

Figure 78. Recompilation Changes List



4. For any change with **Status** of **Unsupported**, you must either revert the change to **Previous value**, or perform a full compilation to implement the change.
5. Click the **Recompile** button, as Recompilation Changes List shows. Recompilation uses the Engineering Change Order (ECO) compilation flow to append your Signal Tap node changes to the existing finalized snapshot, without changing placement and routing outside the Signal Tap partition.

   Note: The recompilation only applies to the project database if the recompilation is successful. Otherwise, the last successful compilation results remain unchanged.
6. View the changes in the following Compilation Reports following recompilation:

Figure 79. Connections to In-System Debugging Report

Lists each tap target and whether the connection successfully routes (is Connected after recompilation)

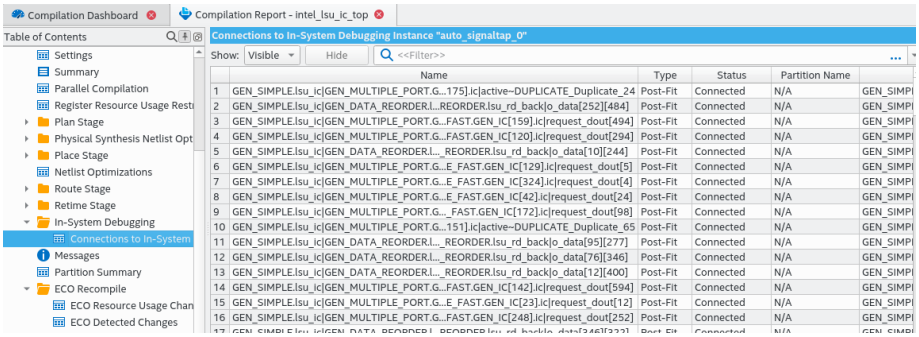


Figure 80. ECO Detected Changes Report

Lists each tap change that you implement with recompilation.

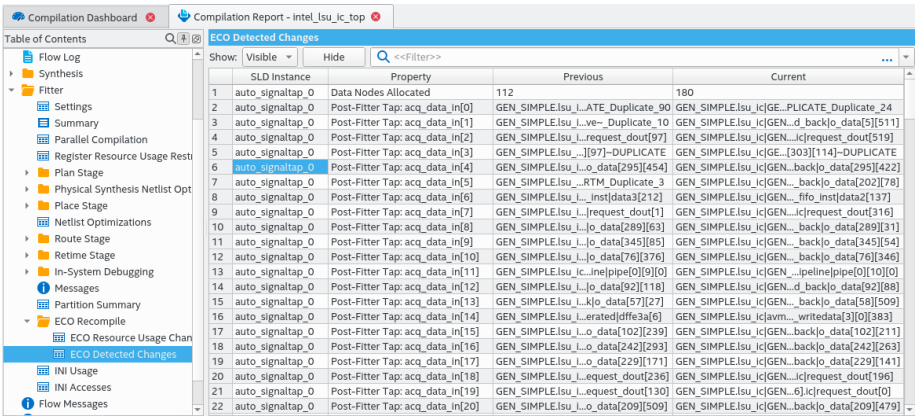

Figure 81. ECO Resource Usage Change

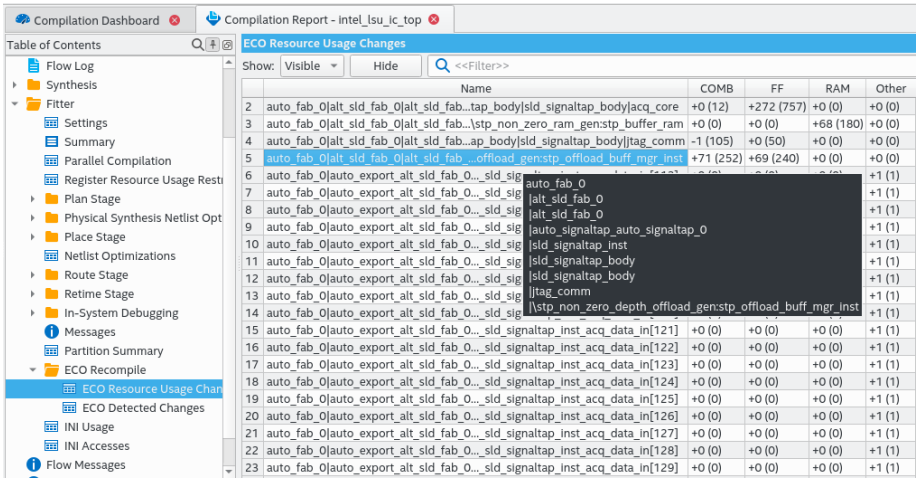
Shows the device resource area change that recompilation implements. Use this report to approximate whether additional changes to the Signal Tap configuration are likely to succeed in combination with the overall design utilization reports.



Related Information

- Recompiling Signal Tap Configuration Changes on page 82
- Using the ECO Compilation Flow in *Intel Quartus Prime Pro Edition User Guide: Design Optimization*

2.7.2. Runtime Reconfigurable Options

When you use Runtime Trigger mode, you can change certain settings in the `.stp` without requiring recompilation of the design.

Table 21. Runtime Reconfigurable Features

Runtime Reconfigurable Setting	Description
Basic Trigger Conditions and Basic Storage Qualifier Conditions	Change without recompiling all signals that have the Trigger condition turned on to any basic trigger condition value
Comparison Trigger Conditions and Comparison Storage Qualifier Conditions	All the comparison operands, the comparison numeric values, and the interval bound values are runtime-configurable. You can also switch from Comparison to **Basic OR** trigger at runtime without recompiling.
Advanced Trigger Conditions and Advanced Storage Qualifier Conditions	Many operators include runtime configurable settings. For example, all comparison operators are runtime-configurable. Configurable settings appear with a white background in the block representation. This runtime reconfigurable option is turned on in the **Object Properties** dialog box.
Switching between a storage-qualified and a continuous acquisition	Within any storage-qualified mode, you can switch to continuous capture mode without recompiling the design. To enable this feature, turn on **disable storage qualifier**.
State-based trigger flow parameters	Refer to *Runtime Reconfigurable Settings, State-Based Triggering Flow*

Runtime Reconfigurable options can save time during the debugging cycle by allowing you to cover a wider possible range of events, without requiring design recompilation. You may experience a slight impact to the performance and logic utilization. You can turn off runtime re-configurability for advanced trigger conditions and the state-based trigger flow parameters, boosting performance and decreasing area utilization.

To configure the `.stp` file to prevent changes that normally require recompilation in the **Setup** tab, select the **Allow Trigger Condition changes only** lock mode above the node list.

This example illustrates a potential use case for Runtime Reconfigurable features, by providing a storage qualified enabled State-based trigger flow description, and showing how to modify the size of a capture window at runtime without a recompile. This example gives you equivalent functionality to a segmented buffer with a single trigger condition where the segment sizes are runtime reconfigurable.

```
state ST1:
if ( condition1 && (c1 <= m) )// each "segment"  triggers on condition // 1
begin                            // m  = number of total "segments"
   start_store;
   increment c1;
   goto ST2:
end

else (c1 > m )                 // This else condition handles the last
                               // segment.
begin
    start_store
    trigger (n-1)
end

state ST2:
if ( c2 >= n)                 //n = number of samples to capture in each
                              //segment.
begin
    reset c2;
    stop_store;
    goto ST1;
end

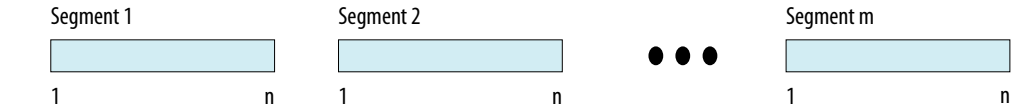
else (c2 < n)
begin
```

```
    increment c2;
    goto ST2;
end
```

Note: *m* x *n* must equal the sample depth to efficiently use the space in the sample buffer.

The next figure shows the segmented buffer that the trigger flow example describes.

Figure 82. Segmented Buffer Created with Storage Qualifier and State-Based Trigger



During runtime, you can modify the values `m` and `n`. Changing the `m` and `n` values in the trigger flow description adjust the segment boundaries without recompiling.

You can add states into the trigger flow description and selectively mask out specific states and enable other ones at runtime with status flags.

This example is like the previous example with an additional state inserted. You use this extra state to specify a different trigger condition that does not use the storage qualifier feature. You insert status flags into the conditional statements to control the execution of the trigger flow.

```
state ST1 :
    if (condition2  && f1)             // additional state for non-segmented
                                       // acquisition set f1 to enable state
        begin
             start_store;
             trigger
        end
    else if (! f1)
        goto ST2;
state ST2:
    if ( (condition1 && (c1 <= m)  && f2) // f2 status flag used to mask state.
Set f2
                                          // to enable
        begin
           start_store;
           increment c1;
           goto ST3:
        end
    else (c1 > m )
           start_store;
   trigger (n-1)
    end
state ST3:
    if ( c2 >= n)
        begin
            reset c2;
            stop_store;
            goto ST1;
        end
    else (c2 < n)
    begin
        increment c2;
        goto ST2;
    end
```

2.7.3. Signal Tap Status Messages

The following table describes the text messages that might appear in the Signal Tap Status Indicator in the **Instance Manager** pane before, during, or after data acquisition. These messages allow you to monitor the state of the logic analyzer and identify the operation that the logic analyzer is performing.

Table 22. Messages in the Signal Tap Status Indicator

Message	Message Description
Not running	The Signal Tap logic analyzer is not running. This message appears when there is no connection to a device, or the device is not configured.
(Power-Up Trigger) Waiting for clock (1)	The Signal Tap logic analyzer is performing a Runtime or Power-Up Trigger acquisition and is waiting for the clock signal to transition.
Acquiring (Power-Up) pre-trigger data (1)	The trigger condition is not yet evaluated. If the acquisition mode is non-segmented buffer, and the storage qualifier type is continuous, the Signal Tap logic analyzer collects a full buffer of data.
Trigger In conditions met	Trigger In conditions are met. The Signal Tap logic analyzer is waiting for the first trigger condition to occur. This message only appears when a Trigger In condition exists.
Waiting for (Power-up) trigger (1)	The Signal Tap logic analyzer is waiting for the trigger event to occur.
Trigger level <x> met	Trigger condition *x* occurred. The Signal Tap logic analyzer is waiting for condition x + 1 to occur.
Acquiring (power-up) post-trigger data (1)	The entire trigger event occurred. The Signal Tap logic analyzer is acquiring the post-trigger data. You define the amount of post-trigger data to collect (between 12%, 50%, and 88%) when you select the non-segmented buffer acquisition mode.
Offload acquired (Power-Up) data (1)	The JTAG chain is transmitting data to the Intel Quartus Prime software.
Ready to acquire	The Signal Tap logic analyzer is waiting for you to initialize the analyzer.

1. This message can appear for both Runtime and Power-Up Trigger events. When referring to a Power-Up Trigger, the text in parentheses appears.

Note: In segmented acquisition mode, pre-trigger and post-trigger do not apply.

2.8. Step 6: Analyze Signal Tap Captured Data

The Signal Tap logic analyzer GUI allows you to examine the data that you capture manually or with a trigger. In the Data view, you can isolate the data of interest with the drag-to-zoom feature, enabled with a left-click. You can save the data for later analysis, or convert the data to other formats for sharing and further study.

- To simplify reading and interpreting the signal data you capture, set up mnemonic tables, either manually or with a plug-in.
- To speed up debugging, use the **Locate** feature in the **Signal Tap node** list to find the locations of problem nodes in other tools in the Intel Quartus Prime software.

The following topics describe viewing, saving, and exporting Signal Tap analysis captured data:

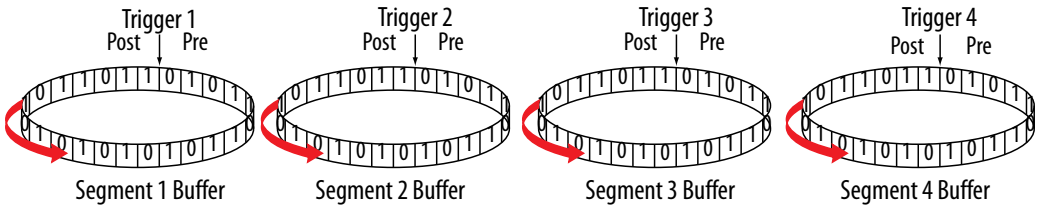
2.8.1. Viewing Capture Data Using Segmented Buffers

Segmented buffers allow you to capture recurring events or sequences of events that span over a long period.

Each acquisition segment acts as a non-segmented buffer, continuously capturing data after activation. When you run analyses with segmented buffers, the Signal Tap logic analyzer captures back-to-back data for each acquisition segment within the data buffer. You define the trigger flow, or the type and order in which the trigger conditions evaluate for each buffer, either in the Sequential trigger flow control or in the Custom State-based trigger flow control.

The following figure shows a segmented acquisition buffer with four segments represented as four separate non-segmented buffers.

Figure 83. Segmented Acquisition Buffer

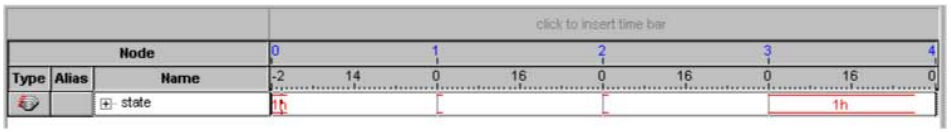


When the Signal Tap logic analyzer finishes an acquisition with a segment and advances to the next segment to start a new acquisition, the data capture that appears in the waveform viewer depends on when a trigger condition occurs. The figure illustrates the data capture method. The Trigger markers—Trigger 1, Trigger 2, Trigger 3 and Trigger 4—refer to the evaluation of the `segment_trigger` and `trigger` commands in the Custom State-based trigger flow. In sequential flows, the Trigger markers for segments 2 through 4 refer to the final trigger condition that you specify within the **Setup** tab.

If the Segment 1 Buffer is the active segment and Trigger 1 occurs, the Signal Tap logic analyzer starts evaluating Trigger 2 immediately. Data Acquisition for the Segment 2 buffer starts when either the Segment 1 Buffer finishes its post-fill count, or when Trigger 2 evaluates as TRUE, whichever condition occurs first. Thus, trigger conditions associated with the next buffer in the data capture sequence can preempt the post-fill count of the current active buffer. This allows the Signal Tap logic analyzer to accurately capture all the trigger conditions that occurred. Unused samples appear as a blank space in the waveform viewer.

Figure 84. Segmented Capture with Preemption of Acquisition Segments

The figure shows a capture using sequential flow control with the trigger condition for each segment specified as **Don't Care**.



Each segment before the last captures only one sample, because the next trigger condition immediately preempts capture of the current buffer. The trigger position for all segments is specified as pre-trigger (12% of the data is before the trigger condition and 88% of the data is after the trigger position). Because the last segment starts immediately with the trigger condition, the segment contains only post-trigger data. The three empty samples in the last segment are left over from the pre-trigger samples that the Signal Tap logic analyzer allocated to the buffer.

For the sequential trigger flow, the **Trigger Position** option applies to every segment in the buffer. A custom state-based trigger flow provides maximum flexibility defining the trigger position. By adjusting the trigger position specific to the debugging requirements, you can help maximize the use of the allocated buffer space.

Related Information

Segmented Buffer on page 45

2.8.2. Viewing Data with Different Acquisition Modes

Different acquisition modes capture different amounts of data immediately after running the Signal Tap logic analyzer and before any trigger conditions occur.

Non-Segmented Buffers in Continuous Mode

In configurations with non-segmented buffers running in continuous mode, the buffer must be full of sampled data before evaluating any trigger condition. Only after the buffer is full, the Signal Tap logic analyzer starts retrieving data through the JTAG connection and evaluates the trigger condition.

If you click the **Stop Analysis** button, Signal Tap prevents the buffer from dumping data during the first acquisition prior to a trigger condition.

Buffers with Storage Qualification

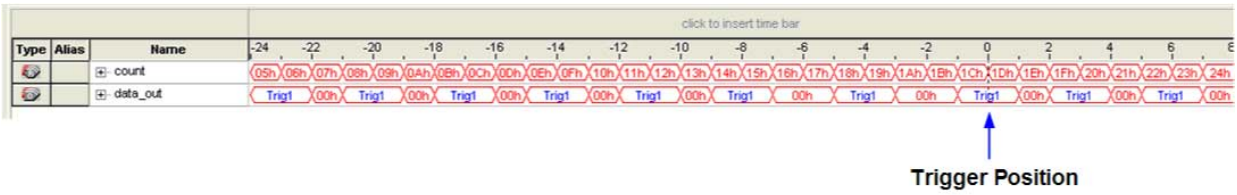
For buffers using a storage qualification mode, the Signal Tap logic analyzer immediately evaluates all trigger conditions while writing samples into the acquisition memory. This evaluation is especially important when using any storage qualification on the data set. The logic analyzer may miss a trigger condition if it waits to capture a full buffer's worth of data before evaluating any trigger conditions.

If a trigger activates before the specified amount of pre-trigger data has occurred, the Signal Tap logic analyzer begins filling memory with post-trigger data, regardless of the amount of pre-trigger data you specify. For example, if you set the trigger position to 50% and set the logic analyzer to trigger on a processor reset, start the logic analyzer, and then power on the target system, the trigger activates. However, the logic analyzer memory contains only post-trigger data, and not any pre-trigger data, because the trigger event has higher precedence than the capture of pre-trigger data.

2.8.2.1. Continuous Mode and a Storage Qualifier Examples

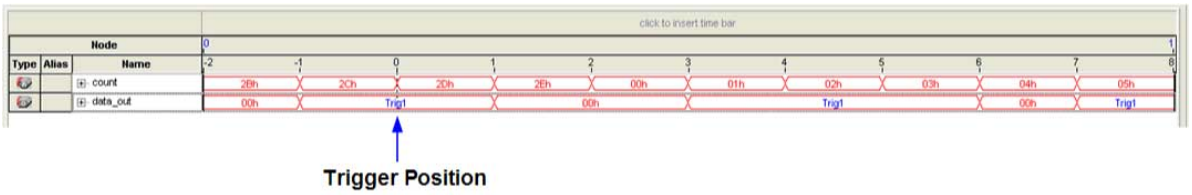
The following show the capture differences between a non-segmented buffer in continuous mode and a non-segmented buffer using a storage qualifier. The configuration of the logic analyzer waveforms is a base trigger condition, sample depth of 64 bits, and **Post trigger position**.

Figure 85. Signal Tap Logic Analyzer Continuous Data Capture



In the continuous data capture, Trig1 occurs several times in the data buffer before the Signal Tap logic analyzer trigger activates. The buffer must be full before the logic analyzer evaluates any trigger condition. After the trigger condition occurs, the logic analyzer continues acquisition for eight additional samples (12% of the buffer, as defined by the "post-trigger" position).

Figure 86. Signal Tap Logic Analyzer Conditional Data Capture



Note to figure:

1. Conditional capture, storage always enabled, post-fill count.
2. The Signal Tap logic analyzer captures a recurring pattern using a non-segmented buffer in conditional mode. The configuration of the logic analyzer is a basic trigger condition "Trig1" and sample depth of 64 bits. The **Trigger in** condition is **Don't care**, so the buffer captures all samples.

In conditional capture the logic analyzer triggers immediately. As in continuous capture, the logic analyzer completes the acquisition with eight samples, or 12% of 64, the sample capacity of the acquisition buffer.

2.8.3. Creating Mnemonics for Bit Patterns

A mnemonic table allows you to assign a meaningful name to a set of bit patterns, such as a bus. To create a mnemonic table:

1. Right-click the **Setup** or **Data** tab of a Signal Tap instance, and click **Mnemonic Table Setup**.
2. Create a mnemonic table by entering sets of bit patterns and specifying a label to represent each pattern.
3. Assign the table to a group of signals by right-clicking the group, clicking **Bus Display Format**, and selecting the mnemonic table.
4. On the **Setup** tab, you can create basic triggers with meaningful names by right-clicking an entry in the **Trigger Conditions** column and selecting a label from the table you assigned to the signal group.

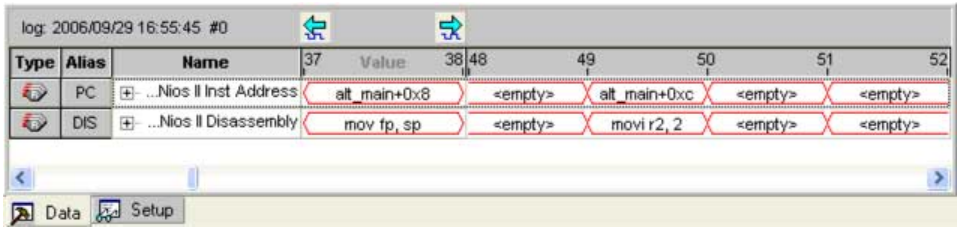
On the **Data** tab, if data captured matches a bit pattern contained in an assigned mnemonic table, the Signal Tap GUI replaces the signal group data with the appropriate label, simplifying the visual inspection of expected data patterns.

2.8.3.1. Adding Mnemonics with a Plug-In

When you use a plug-in to add signals to an `.stp`, mnemonic tables for the added signals are automatically created and assigned to the signals defined in the plug-in. To enable these mnemonic tables manually, right-click the name of the signal or signal group. On the **Bus Display Format** shortcut menu, click the name of the mnemonic table that matches the plug-in.

As an example, the Nios II plug-in helps you to monitor signal activity for your design as the code is executed. If you set up the logic analyzer to trigger on a function name in your Nios II code based on data from an `.elf`, you can see the function name in the **Instruction Address** signal group at the trigger sample, along with the corresponding disassembled code in the **Disassembly** signal group, as shown in Figure 13–52. Captured data samples around the trigger are referenced as offset addresses from the trigger function name.

Figure 87. Data Tab when the Nios II Plug-In is Used



2.8.4. Locating a Node in the Design

When you find the source of an error in your design using the Signal Tap logic analyzer, you can use the node locate feature to locate that signal in various Intel Quartus Prime design visualization tools, as well as in the design file. Locating the node allows you to visualize the source of the problem quickly and correct the issue. To locate a signal from the Signal Tap logic analyzer, right-click the signal in the `.stp`, and click **Locate in ➤ <tool name>**.

You can locate a signal from the node list with the following tools:

- Assignment Editor
- Pin Planner
- Timing Closure Floorplan
- Chip Planner
- Resource Property Editor
- Technology Map Viewer
- RTL Viewer
- Design File

2.8.5. Saving Captured Signal Tap Data

When you save a data capture, the Signal Tap logic analyzer stores this data in the active `.stp` file, and the **Data Log** adds the capture as a log entry under the current configuration.

When you set Signal Tap analysis to **Autorun Analysis**, which starts the Signal Tap logic analyzer in a repetitive acquisition mode, the logic analyzer creates a separate entry in the **Data Log** to store the data captured each time the trigger occurs. This preservation allows you to review the captured data for each trigger event.

The default name for a log derives from the time stamp when the logic analyzer acquires the data. As a best practice, rename the data log with a more meaningful name.

The organization of logs is hierarchical; the logic analyzer groups similar logs of captured data in trigger sets.

Related Information

Data Log Pane on page 101

2.8.6. Exporting Captured Signal Tap Data

You can export captured data to the following file formats, for use with other EDA simulation tools:

- Comma Separated Values File (`.csv`)
- Table File (`.tbl`)
- Value Change Dump File (`.vcd`)
- Vector Waveform File (`.vwf`)
- Graphics format files (`.jpg`, `.bmp`)

To export the captured data from the Signal Tap logic analyzer, click **File ➤ Export**, and then specify the **File Name**, **Export Format**, and **Clock Period**.

2.8.7. Creating a Signal Tap List File

You can generate a Signal Tap list file that contains all the data the logic analyzer captures for a trigger event, in text format.

The Signal Tap list file is especially useful when combined with a plug-in that includes instruction code disassembly. You can view the order of instruction code execution during the same time period of the trigger event.

To create a Signal Tap list file, click **File ➤ Create/Update ➤ Create Signal Tap List File**.

Each row of the list file corresponds to one captured sample in the buffer. Columns correspond to the value of each of the captured signals or signal groups for that sample. If you defined a mnemonic table for the captured data, a matching entry from the table replaces the numerical values in the list.

2.9. Other Signal Tap Debugging Flows

Refer to the following information about more advanced (non-standard) Signal Tap debugging flows and alternative methods.

2.9.1. Signal Tap and Simulator Integration

You can use Signal Tap signal and acquisition data directly in your supported simulator for enhanced visibility into internal signal states in a design hierarchy. The **Add Simulator Aware Nodes** command intelligently analyzes the circuit to determine the minimum set of nodes needed to tap to gain full visibility into the selected hierarchy's cone of logic.

Signal Tap can also transform the Signal Tap data into an RTL simulation testbench for any level of the design hierarchy. This simulation testbench allows you to export acquired Signal Tap hardware data directly into your RTL simulator and observe signal states beyond Signal Tap observability.

The following topics describe these Signal Tap and Simulator Integration features in detail:

- Adding Simulator-Aware Signal Tap Nodes on page 48
- Generating a Simulation Testbench from Signal Tap Data on page 98

Simulator Integration Beta Limitations

This version of the Signal Tap and simulator integration feature is a beta release. The following known limitations apply to this beta release:

- Supports only Verilog HDL simulation.
- Supports testbench generation only within the current project directory.

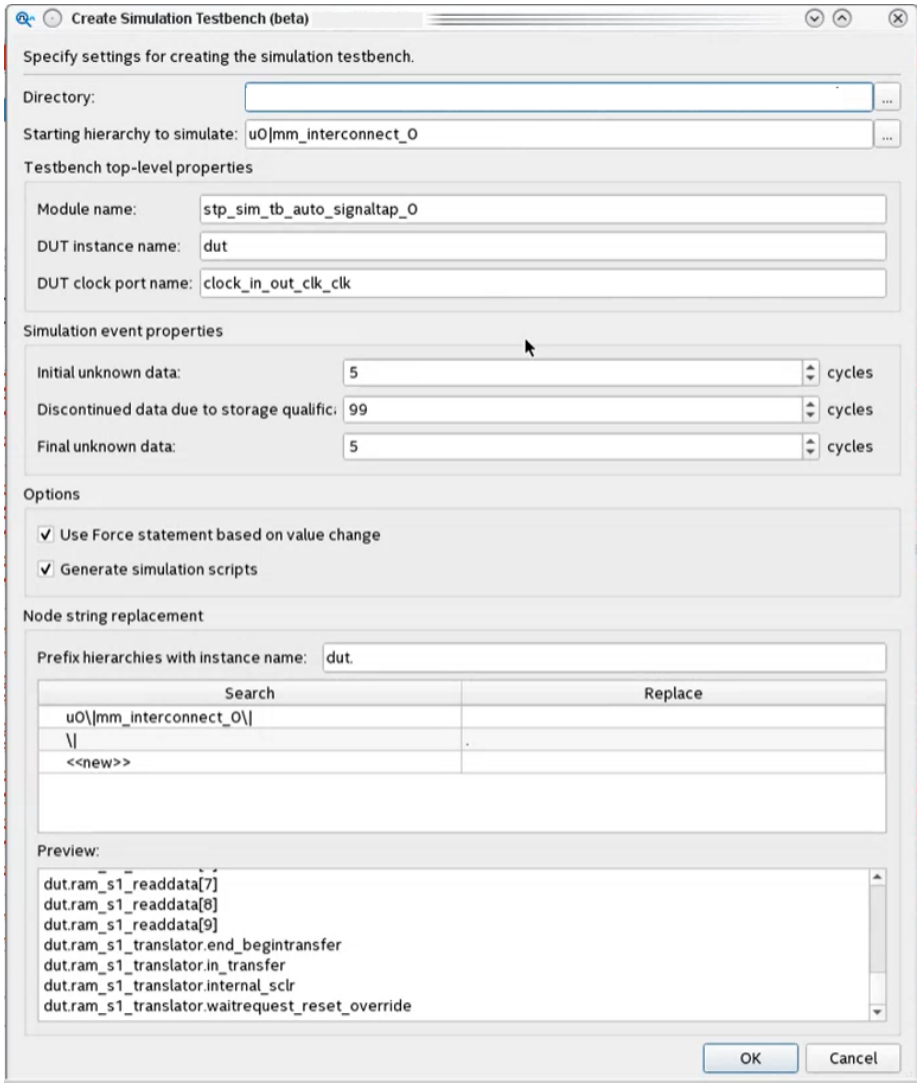
2.9.1.1. Generating a Simulation Testbench from Signal Tap Data

You can use Signal Tap to capture signal data about your running system, and then automatically generate an RTL simulation testbench directly from this capture data for use in your supported simulator.

To generate a simulation testbench from Signal Tap data, follow these steps:

1. Add simulator-aware Signal Tap nodes to the logic analyzer, as Adding Simulator-Aware Signal Tap Nodes on page 48 describes.
2. Run Signal Tap analysis, as Step 5: Run the Signal Tap Logic Analyzer on page 86 describes.

Figure 88. Create Simulation Testbench



3. In the Signal Tap window, click **File ➤ Create Simulation Testbench**. Retain defaults and click **OK**. The testbench generates in a vendor-specific directory. Refer to Create Simulation Testbench Dialog Box Settings on page 100.
4. Source the generated simulator setup script in your supported simulator. For example:

```
source msim_setup.tcl
```

5. Use the commands in the setup script to compile and load the testbench into a supported simulator. For example, in the Questa or ModelSim simulators:

```
ld_debug
```

   Note: Signal Tap uses a Verilog HDL `force` statement to inject the Signal Tap data into the simulator.

6. Add signals to the waveform and run the simulation in your simulator.
7. View the results of simulation in your simulator.

2.9.1.2. Create Simulation Testbench Dialog Box Settings

The following options are available for RTL simulation testbench generation from the Signal Tap **Create Simulation Testbench Dialog Box**. The default values derive from Signal Tap signal data.

Table 23. Create Simulation Testbench Dialog Box (Signal Tap Logic Analyzer)

Name	Description
Directory	Specifies the directory to generated save RTL simulation testbench files. *Note:* Signal Tap currently supports testbench generation only within the current project directory.
Starting hierarchy to simulate	Specifies the design hierarchy level to include in the simulation. The default location is a subdirectory of the project with the hierarchy name.
Testbench top level properties	Specifies the following testbench properties. By default, these values populate from the Signal Tap data: • **Module name**—specifies the name of the design module that you want to simulate, as specified in Signal Tap • **DUT instance name**—specifies the default instance name for the design under test (DUT) in your simulator. The default is **DUT**. This name appears in your simulator. • **DUT clock port name**—specifies the clock port name of the design under test (DUT) for simulation. Signal Tap automatically derives this value based on the **DUT instance name**.
Simulation event properties	Specifies the following testbench properties. By default, these values populate from the Signal Tap data: • **Initial unknown data**—specifies the number of clock cycles for which the data value is initially unknown at the start of simulation. • **Discontinued data due to storage qualification**—specifies the number of clock cycles for which the data is discontinued because of lack of storage. • **Final unknown data**—specifies the number of clock cycles for which the data is unknown initially at the end of simulation.
Options	The following options must be enabled for testbench generation: • **Use force statement based on value change**—specifies the number of clock cycles for which the data value is initially unknown at the start of simulation. *Note:* Signal Tap uses a Verilog HDL `force` statement to inject the Signal Tap data into the simulator. • **Generate simulation scripts**—specifies that simulation scripts generate in vendor specific subdirectories during testbench generation. Source these scripts in your simulator to setup simulation.
Node string replacement	Specifies options for nomenclature and syntax within the generated testbench:

continued...

Name	Description
	• **Prefix hierarchies with instance name**—specifies the instance name that prepends to hierarchy names in the testbench. In general, the derived default value is suitable. • **Search|Replace**—specifies the search and replace strings for **Node string replacement**.
Preview	Displays the result of the **Node string replacement** settings within the testbench.

2.9.2. Managing Multiple Signal Tap Configurations

You can debug different blocks in your design by grouping related monitoring signals. Similarly, you can use a group of signals to define multiple trigger conditions. Each combination of signals, capture settings, and trigger conditions determines a debug configuration, and one configuration can have zero or more associated data logs.

You can save each debug configuration as a different `.stp` file. Alternatively, you can embed multiple configurations within the same `.stp` file, and use the **Data Log** to view and manage each debug configuration.

Note: Each `.stp` pertains to a specific programming (`.sof`) file. To function correctly, the settings in the `.stp` file you use at runtime must match the Signal Tap specifications in the `.sof` file that you use to program the device.

Related Information

Ensure Compatibility Between .stp and .sof Files on page 85

2.9.2.1. Data Log Pane

The **Data Log** pane displays all Signal Tap configurations and data capture results that a single `.stp` file stores.

- To save the current configuration or capture in the **Data Log** of the current `.stp` file, click **Edit ➤ Save to Data Log**.
- To automatically generate a log entry after every data capture, click **Edit ➤ Enable Data Log**. Alternatively, enable the box at the top of the **Data Log** pane.

The **Data Log** displays its contents in a tree hierarchy. The active items display a different icon.

Table 24. Data Log Items

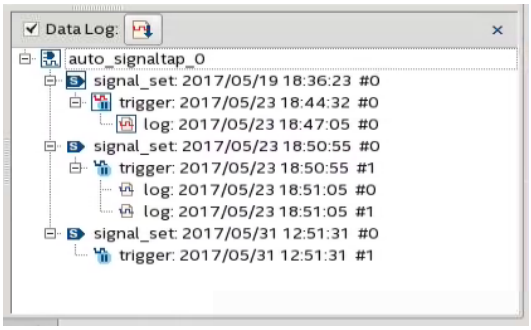
Item	Icon		Contains one or more	Comments
	Unselected	Selected		
Instance			Signal Set	The top-level for a particular Signal Tap instance.
Signal Set			Trigger	The Signal Set changes whenever you add a new signal to a Signal Tap instance. After a change in the Signal Set, you need to recompile.
Trigger			Capture Log	A trigger changes when you change any trigger condition. Some of these changes do not require recompilation.
Capture Log				Contains captured sample data for this particular trigger configuration, for the particular signal set for this particular Signal Tap instance. There can be multiple capture logs for a particular setup if you run the logic analyzer multiple times, as Simple Data Log shows.

The name on each entry displays the wall-clock time when the Signal Tap logic analyzer triggers, and the time elapsed from start acquisition to trigger activation. You can rename entries.

To switch between configurations, double-click an entry in the **Data Log**. As a result, the **Setup** and **Data** tabs update to display the active signal list, trigger conditions, or specified captured data.

Figure 89. Simple Data Log

In this example, the **Data Log** displays one instance with three signal set configurations, two trigger condition setups, and three different captured data sets.



2.9.2.2. SOF Manager

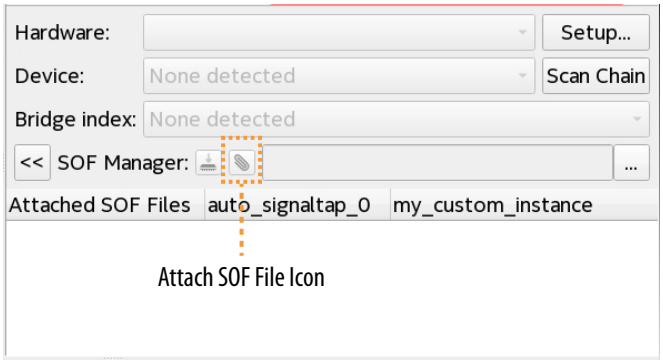
The SOF Manager is in the **JTAG Chain Configuration** pane.

With the SOF Manager you can attach multiple `.sof` files to a single `.stp` file. This attachment allows you to move the `.stp` file to a different location, either on the same computer or across a network, without including the attached `.sof` separately.

The SOF Manager also ensures compatibility between any attached `.sof` files and the current `.stp` file settings automatically, as Ensure Compatibility Between .stp and .sof Files on page 85 describes.

To attach a new `.sof` in the `.stp` file, click the **Attach SOF File** icon .

Figure 90. SOF Manager



As you switch between configurations in the **Data Log**, you can extract the `.sof` that is compatible with that configuration.

To download the new `.sof` to the FPGA, click the **Program Device** icon in the SOF Manager, after ensuring that the configuration of your `.stp` is compatible with the design to program into the target device.

Related Information

Data Log Pane on page 101

2.9.3. Debugging Partial Reconfiguration Designs with Signal Tap

You can debug a Partial Reconfiguration (PR) design with the Signal Tap logic analyzer. The Signal Tap logic analyzer supports data acquisition in the static and PR regions. You can debug multiple personas present in a PR region and multiple PR regions.

For examples on debugging PR designs targeting specific devices, refer to *AN 841: Signal Tap Tutorial for Intel Stratix® 10 Partial Reconfiguration Design* or *AN 845: Signal Tap Tutorial for Intel Arria® 10 Partial Reconfiguration Design*.

Related Information

- AN 841: Signal Tap Tutorial for Intel Stratix 10 Partial Reconfiguration Design
- AN 845: Signal Tap Tutorial for Intel Arria 10 Partial Reconfiguration Design

2.9.3.1. Signal Tap Guidelines for PR Designs

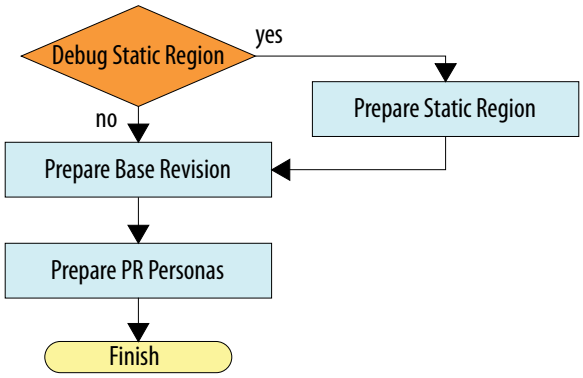
Follow these guidelines to obtain the best results when debugging PR designs with the Signal Tap logic analyzer:

- Include one `.stp` file per project revision.
- Tap pre-synthesis nodes only. In the Node Finder, filter by **Signal Tap: pre-synthesis**.
- Do not tap nodes in the default persona (the personas you use in the base revision compile). Create a new PR implementation revision that instantiates the default persona, and tap nodes in the new revision.

- Store all the tapped nodes from a PR persona in one `.stp` file, to enable debugging the entire persona using only one Signal Tap window.
- Do not tap across PR regions, or from a static region to a PR region in the same `.stp` file.
- Each Signal Tap window opens only one `.stp` file. Therefore, to debug more than one partition simultaneously, you must use stand-alone Signal Tap from the command-line.

2.9.3.2. PR Design Setup for Signal Tap Debug

Figure 91. Setting Up PR Design for Debug with Signal Tap



To debug a PR design, you must instantiate SLD JTAG bridges when generating the base revision, and then define debug components for all PR personas. Optionally, you can specify signals to tap in the static region. After configuring all the PR personas in the design, you can continue the PR design flow.

Related Information

- Debug Fabric for Partial Reconfiguration Designs on page 20
- Partial Reconfiguration Design Flow, Intel Quartus Prime Pro Edition User Guide: Partial Reconfiguration

2.9.3.2.1. Preparing the Static Region for Signal Tap Debugging

To debug the static region in your PR design:

1. Tap nodes in the static region exclusively.
2. Save the `.stp` file with a name that identifies the file with the static region.
3. Enable Signal Tap in your project, and include the `.stp` file in the base revision.

Note: Do not tap signals in the default PR personas.

2.9.3.2.2. Preparing the Base Revision for Signal Tap Debugging

In the base revision, for each PR region that you want to debug in the design:

1. Instantiate the SLD JTAG Bridge Agent Intel FPGA IP in the static region.
2. Instantiate the SLD JTAG Bridge Host Intel FPGA IP in the PR region of the default persona.

You can use the IP Catalog or Platform Designer to instantiate SLD JTAG Bridge components.

Related Information

- Instantiating the SLD JTAG Bridge Agent on page 17
- Instantiating the SLD JTAG Bridge Host on page 18

2.9.3.2.3. Preparing PR Personas for Signal Tap Debugging

Before you create revisions for personas in your design, you must instantiate debug IP components and tap signals.

For each PR persona that you want to debug:

1. Instantiate the SLD JTAG Bridge Host Intel FPGA IP in the PR persona.
2. Tap pre-synthesis nodes in the PR persona only.
3. Save in a new `.stp` file with a name that identifies the persona.
4. Use the new `.stp` file in the implementation revision.

If you do not want to debug a particular persona, drive the `tdo` output signal to 0.

2.9.3.3. Performing Data Acquisition in a PR design

After generating the `.sof` and `.rbf` files for the revisions you want to debug, you are ready to program your device and debug with the Signal Tap logic analyzer.

To perform data acquisition:

1. Program the base image into your device.
2. Partially reconfigure the device with the persona that you want to debug.
3. Open the Signal Tap logic analyzer by clicking **Tools ➤ Signal Tap logic analyzer** in the Intel Quartus Prime software.

   The logic analyzer opens and loads the `.stp` file set in the current active revision.
4. To debug other regions in your design, open new Signal Tap windows by opening the other region's `.stp` file from the Intel Quartus Prime main window.

   Alternatively, use the command-line:

   ```
   quartus_stpw <stp_file_other_region.stp>
   ```
5. Debug your design with Signal Tap.

To debug another revision, you must partially reconfigure your design with the corresponding `.rbf` file.

2.9.4. Debugging Block-Based Designs with Signal Tap

The Intel Quartus Prime Pro Edition software supports verification of block-based design flows with the Signal Tap logic analyzer.

Verifying a block-based design requires planning to ensure visibility of logic inside partitions and communication with the Signal Tap logic analyzer. The preparation steps depend on whether you are reusing a core partition or a root partition.

For information about designing with reusable blocks, refer to the *Intel Quartus Prime Pro Edition User Guide: Block-Based Design*. For step-by-step block-based design debugging instructions, refer to *AN 847: Signal Tap Tutorial with Design Block Reuse for Intel Arria 10 FPGA Development Board*.

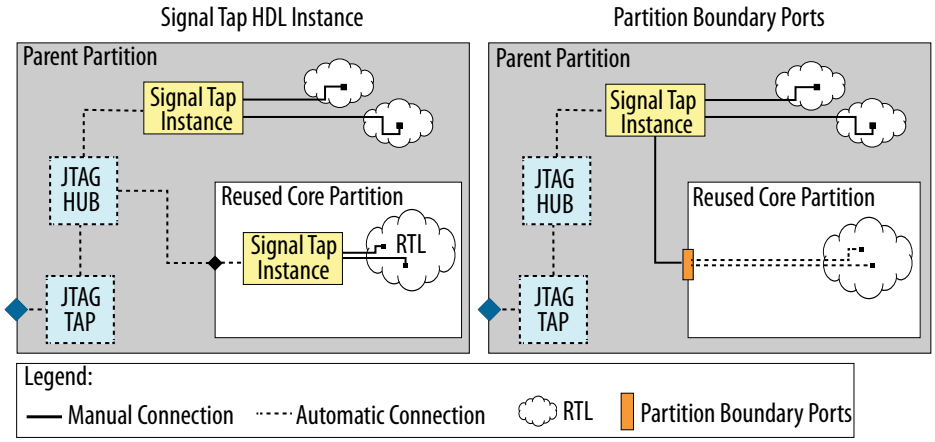
Related Information

Intel Quartus Prime Pro Edition User Guide: Block-Based Design

2.9.4.1. Signal Tap Debugging with a Core Partition

To perform Signal Tap debugging in a core design partition that you reuse from another project, you identify the signals of interest, and then make those signals visible to a Signal Tap logic analyzer instance. The Intel Quartus Prime software supports two methods to make the reused core partition signals visible for Signal Tap monitoring: by creating partition boundary ports, or by Signal Tap HDL instantiation.

Figure 92. Debug Setup with Reused Core Partition



2.9.4.1.1. Partition Boundary Ports Method

Partition boundary ports expose core partition nodes to the top-level partition. Boundary ports simplify the management of hierarchical blocks by tunneling through layers of logic without making RTL changes. The partition boundary ports method includes these high-level steps:

1. In the project that exports the partition, define boundary ports for all potential Signal Tap nodes in the core partition. Define partition boundary ports with the **Create Partition Boundary Ports** assignment in the Assignment Editor. When you assign a bus, the assignment applies to the root name of the debug port, with each bit enumerated.
2. In the project that exports the partition, create a black box file that includes the partition boundary ports, to allows tapping these ports as pre-synthesis or post-fit nodes in another project.
3. In the project that reuses the partition, run Analysis & Synthesis on the reused partition. All valid ports with the **Create Partition Boundary Ports** become visible in the project. After synthesis you can verify the partition boundary ports in the Create Partition Boundary Ports report in the **In-System Debugging** folder under **Synthesis** reports.
4. Tap the partition boundary ports to connect to a Signal Tap instance in the top-level partition. You can also tap logic from the top-level partition to this Signal Tap instance. When using this method, the project requires only one Signal Tap instance to debug both the top-level and the reused core partition.

The following procedures explain these steps in more detail.

2.9.4.1.2. Debug a Core Partition through Partition Boundary Ports

To use Signal Tap to debug a design that includes a core partition exported with partition boundary ports from another project, follow these steps:

1. Add to your project the black-box file that you create in Export a Core Partition with Partition Boundary Ports on page 107.
2. To run synthesis, double-click **Analysis & Synthesis** on the Compilation Dashboard.
3. Define a Signal Tap instance with the Signal Tap GUI, or by instantiating a Signal Tap HDL instance in the top level root partition, as Step 1: Add the Signal Tap Logic Analyzer to the Project on page 34 describes.
4. Connect the partition boundary ports of the reused core partition to the HDL instance, or add post-synthesis or post-fit nodes to the **Signal Configuration** tab in the Signal Tap logic analyzer GUI.
5. To create a design partition, click **Assignments ➤ Design Partitions Window**. Define a partition and assign the exported partition `.qdb` file as the **Partition Database File** option.
6. Compile the design, including all partitions and the Signal Tap instance.
7. Program the Intel FPGA device with the design and Signal Tap instances.
8. Perform data acquisition with the Signal Tap logic analyzer GUI.

2.9.4.1.3. Export a Core Partition with Partition Boundary Ports

To export a core partition with partition boundary ports for reuse and Signal Tap debugging in another project, follow these steps:

1. To run synthesis, double-click **Analysis & Synthesis** on the Compilation Dashboard.
2. Define a design partition for reuse that contains only core logic. Click **Assignments ➤ Design Partitions Window** to define the partition.
3. To create partition boundary ports for the core partition, specify the **Create Partition Boundary Ports** assignment in the Assignment Editor for partition ports.
4. Click **Project ➤ Export Design Partition**. By default, the `.qdb` file you export includes any Signal Tap HDL instances for the partition.
5. Compile the design and Signal Tap instance.
6. Create a black box file that defines only the port and module or entity definitions, without any logic.
7. Manually copy the exported partition `.qdb` file and any black box file to the other project.

Optionally, you can verify signals in the root and core partitions in the Developer project with the Signal Tap logic analyzer.

2.9.4.1.4. Signal Tap HDL Instance Method

To use the Signal Tap HDL instance method, you first create a Signal Tap HDL instance in the reusable core partition, and then connect the signals of interest to that instance. The Compiler ensures top-level visibility of Signal Tap instances inside partitions. Since the root partition and the core partition have separated HDL instances, the Signal Tap files are also separate.

When you reuse the partition in another project, you must generate one Signal Tap file in the target project for each HDL instance present in the reused partition.

Debug a Core Partition Exported with Signal Tap HDL Instances

To use Signal Tap to debug a design that includes a core partition exported with Signal Tap HDL instances, follow these steps:

1. Add to your project the black-box file that you create in Export a Core Partition with Signal Tap HDL Instances on page 109.
2. To create a design partition, click **Assignments ➤ Design Partitions Window**. Define a partition and assign the exported partition `.qdb` file as the **Partition Database File** option.
3. Create a Signal Tap file for the top-level partition as Step 1: Add the Signal Tap Logic Analyzer to the Project on page 34 describes.
4. Compile the design and Signal Tap instances.
5. Generate a Signal Tap file for the reused Core Partition with the **File ➤ Create/Update ➤ Create Signal Tap File from Design Instance** command.
6. Program the Intel FPGA device with the design and Signal Tap instances.
7. Perform hardware verification of top-level partition with the Signal Tap instance defined in Step 3.
8. Perform hardware verification of the Reused Core Partition with the Signal Tap instance defined in Step 5.

2.9.4.1.5. Export a Core Partition with Signal Tap HDL Instances

To export a core partition with Signal Tap HDL instances for reuse and eventual Signal Tap debugging in another project, follow these steps:

1. To run synthesis, double-click **Analysis & Synthesis** on the Compilation Dashboard.
2. Define a design partition for reuse that contains only core logic. Click **Assignments ➤ Design Partitions Window** to define the partition.
3. Add a Signal Tap HDL instance to the core partition, connecting it to nodes of interest.
4. Click **Project ➤ Export Design Partition**. By default, the `.qdb` file you export includes any Signal Tap HDL instances for the partition.
5. Create a black box file that defines only the port and module or entity definitions, without any logic.
6. Manually copy the exported partition `.qdb` file and any black box file to the other project.

2.9.4.1.6. Debug a Core Partition Exported with Signal Tap HDL Instances

To use Signal Tap to debug a design that includes a core partition exported with Signal Tap HDL instances, follow these steps:

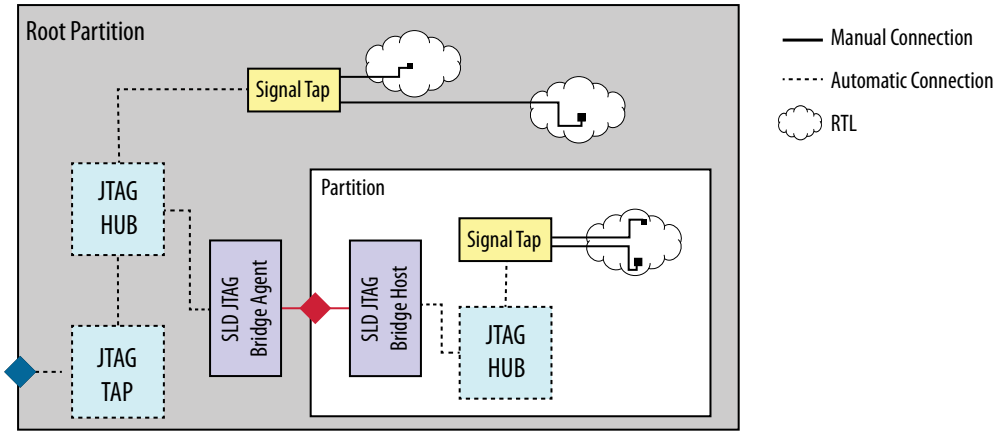
1. Add to your project the black-box file that you create in Export a Core Partition with Signal Tap HDL Instances on page 109.
2. To create a design partition, click **Assignments ➤ Design Partitions Window**. Define a partition and assign the exported partition `.qdb` file as the **Partition Database File** option.
3. Create a Signal Tap file for the top-level partition as Step 1: Add the Signal Tap Logic Analyzer to the Project on page 34 describes.
4. Compile the design and Signal Tap instances.
5. Generate a Signal Tap file for the reused Core Partition with the **File ➤ Create/Update ➤ Create Signal Tap File from Design Instance** command.
6. Program the Intel FPGA device with the design and Signal Tap instances.
7. Perform hardware verification of top-level partition with the Signal Tap instance defined in Step 3.
8. Perform hardware verification of the Reused Core Partition with the Signal Tap instance defined in Step 5.

2.9.4.2. Signal Tap Debugging with a Root Partition

In a project that reuses a root partition, you enable debugging of the root partition and the core partition independently, with separate Signal Tap instances in each partition. In the project that exports the partition, you add the Signal Tap instance to the root partition. Additionally, you extend the debug fabric into the reserved core partition with a debug bridge. This bridge allows subsequent instantiation of Signal Tap when reusing the partition in another project.

You implement the debug bridge with the SLD JTAG Bridge Agent Intel FPGA IP and SLD JTAG Bridge Host Intel FPGA IP pair for each reserved core boundary in the design. You instantiate the SLD JTAG Bridge Agent IP in the root partition, and the SLD JTAG Bridge Host IP in the core partition.

Figure 93. Debug Setup with Reused Root Partition



For details about the debug bridge, refer to the *SLD JTAG Bridge* in the *System Debugging Tools Overview* chapter.

Related Information

SLD JTAG Bridge on page 14

2.9.4.2.1. Export the Root Partition with SLD JTAG Bridge

To export a reusable root partition with SLD JTAG Bridge that allows debugging of core partitions in another project, follow these steps.

1. Create a reserved core partition and define a Logic Lock region.
2. Generate and instantiate SLD JTAG Bridge Agent in the root partition.

   The combination of agent and host allows debugging the reserved core partition in Consumer projects.
3. Generate and instantiate the SLD JTAG Bridge Host in the reserved core partition.
4. Add a Signal Tap instance to the root partition, as Step 1: Add the Signal Tap Logic Analyzer to the Project on page 34 describes.
5. In the Signal Tap instance, specify the signals for monitoring. This action allows debugging the root partition in the Developer and Consumer projects.
6. Compile the design and Signal Tap instance.
7. Click **Project ➤ Export Design Partition**. By default, the `.qdb` file you export includes any Signal Tap HDL instances for the partition.
8. Manually copy files to the project that reuses the root partition:
   - In designs targeting the Intel Arria 10 device family, copy `.qdb` and `.sdc` files.
   - In designs targeting the Intel Stratix 10 device family copy the `.qdb` file.

In designs with multiple child partitions, you must provide the hierarchy path and the associated index of the JTAG Bridge Instance Agents in the design to the Consumer.

2.9.4.2.2. Debugging an Exported Root Partition and Core Partition Simultaneously using the SLD JTAG Bridge

When you reuse an exported root partition in another project, the exported `.qdb` includes the Signal Tap connection to signals in the root partition, and the SLD JTAG Bridge Agent IP, which allows debugging logic in the core partition.

To perform Signal Tap debugging in a project that includes a reused root partition:

1. Add the exported `.qdb` (and `.sdc`) files to the project that reuses them.
2. From the IP Catalog, parameterize and instantiate the SLD JTAG Bridge Host Intel FPGA IP in the core partition.
3. Run the Analysis & Synthesis stage of the Compiler.
4. Create a Signal Tap instance in the core partition, as Step 1: Add the Signal Tap Logic Analyzer to the Project on page 34 describes.
5. In the Signal Tap instance, specify post-synthesis signals for monitoring.

   Note: You can only tap signals in the core partition.
6. Compile the design and Signal Tap instance.
7. Generate a Signal Tap file for the reused root partition with the `quartus_stp` command.
8. Program the device.
9. Perform hardware verification of the reserved core partition with the Signal Tap instance defined in Step 3.
10. Perform hardware verification of the reused root partition with the Signal Tap instance defined in Step 7.

2.9.4.3. Compiler Snapshots and Signal Tap Debugging

When you reuse a design partition exported from another project, the design partition preserves the results of a specific snapshot of the compilation. Whenever possible, it is easiest to specify the signals for monitoring in the original project that exports the partition.

Adding new signals to a Signal Tap instance in a reused partition requires the Fitter to connect and route these signals. This is only possible when:

- The reused partition contains the Synthesis snapshot—reused partitions that contain the Placed or Final snapshot do not allow adding more signals to the Signal Tap instance for monitoring, because you cannot create additional boundary ports.
- The signal that you want to tap is a post-fit signal—adding pre-synthesis Signal Tap signals is not possible, because that requires resynthesis of the partition.

Related Information

Signals Unavailable for Signal Tap Debugging on page 51

2.9.4.3.1. Add Post-Fit Nodes when Reusing a Partition Containing a Synthesis Snapshot

You can add post-fit nodes for Signal Tap debug when reusing a design partition containing the synthesis snapshot exported from another project.

To add post-fit nodes to Signal Tap for monitoring:

1. Open the project that reuses the partition, and then compile the reused partition through the Fitter stage.
2. Add a Signal Tap instance to the project that reuses the partition, as Step 1: Add the Signal Tap Logic Analyzer to the Project on page 34 describes.
3. In the Signal Tap GUI, add the post-fit Signal Tap nodes to the **Signal Configuration** tab.
4. Recompile the design from the Place stage by clicking **Processing ➤ Start ➤ Start Fitter (Place)**.

   The Fitter attaches the Signal Tap nodes to the existing synthesized nodes.

2.9.5. Debugging Devices that use Configuration Bitstream Security

Some Intel FPGA device families support bitstream decryption during configuration using an on-device AES decryption engine. You can still use the Signal Tap logic analyzer to analyze functional data within the FPGA with such devices. However, JTAG configuration is not possible after programming the security key into the device.

Use an unencrypted bitstream during the prototype and debugging phases of the design, to allow programming file generation and reconfiguration of the device over the JTAG connection while debugging.

If you must use the Signal Tap logic analyzer with an encrypted bitstream, first configure the device with an encrypted configuration file using Passive Serial (PS), Fast Passive Parallel (FPP), or Active Serial (AS) configuration modes. The design must contain at least one instance of the Signal Tap logic analyzer. After configuring the FPGA with a Signal Tap instance and the design, you can open the Signal Tap logic analyzer GUI and scan the chain to acquire data with the JTAG connection.

2.9.6. Signal Tap Data Capture with the MATLAB MEX Function

When you use MATLAB for DSP design, you can acquire data from the Signal Tap logic analyzer directly into a matrix in the MATLAB environment. To use this method, you call the MATLAB MEX function, `alt_signaltap_run`, that the Intel Quartus Prime software includes. If you use the MATLAB MEX function in a loop, you can perform as many acquisitions in the same amount of time as when using Signal Tap in the Intel Quartus Prime software environment.

Note: The MATLAB MEX function for Signal Tap is available in the Windows* version and Linux version of the Intel Quartus Prime software. This function is compatible with MATLAB Release 14 Original Release Version 7 and later.

To set up the Intel Quartus Prime software and the MATLAB environment to perform Signal Tap acquisitions:

1. In the Intel Quartus Prime software, create an `.stp` file.
2. In the node list in the **Data** tab of the Signal Tap logic analyzer Editor, organize the signals and groups of signals into the order in which you want them to appear in the MATLAB matrix.

   Each column of the imported matrix represents a single Signal Tap acquisition sample, while each row represents a signal or group of signals in the order you defined in the **Data** tab.

   Note: Signal groups that the Signal Tap logic analyzer acquires and transfers into the MATLAB MEX function have a width limit of 32 signals. To use the MATLAB MEX function with a bus or signal group that contains more than 32 signals, split the group into smaller groups that do not exceed the limit.
3. Save the `.stp` file and compile your design. Program your device and run the Signal Tap logic analyzer to ensure your trigger conditions and signal acquisition work correctly.
4. In the MATLAB environment, add the Intel Quartus Prime binary directory to your path with the following command:

   ```
   addpath <Quartus install directory>\win
   ```

   You can view the help file for the MEX function by entering the following command in MATLAB without any operators:

   ```
   alt_signaltap_run
   ```
5. Use the MATLAB MEX function to open the JTAG connection to the device and run the Signal Tap logic analyzer to acquire data. When you finish acquiring data, close the JTAG connection.

   To open the JTAG connection and begin acquiring captured data directly into a MATLAB matrix called `stp`, use the following command:

   ```
   stp = alt_signaltap_run \
   ('<stp filename>'[,('signed'|'unsigned')[,'<instance names>'[, \
   '<signalset name>'[,'<trigger name>']]]]);
   ```

   When capturing data, you must assign a filename, for example, *<stp filename>* as a requirement of the MATLAB MEX function. The following table describes other MATLAB MEX function options:

Table 25. Signal Tap MATLAB MEX Function Options

Option	Usage	Description
`signed` `unsigned`	`'signed'` `'unsigned'`	The **signed** option turns signal group data into 32-bit two's-complement signed integers. The MSB of the group as defined in the Signal Tap **Data** tab is the sign bit. The **unsigned** option keeps the data as an unsigned integer. The default is **signed**.
<instance name>	`'auto_signaltap_0'`	Specify a Signal Tap instance if more than one instance is defined. The default is the first instance in the `.stp`, `auto_signaltap_0`.
<signal set name> *<trigger name>*	`'my_signalset'` `'my_trigger'`	Specify the signal set and trigger from the Signal Tap data log if multiple configurations are present in the `.stp`. The default is the active signal set and trigger in the file.

During data acquisition, you can enable or disable verbose mode to see the status of the logic analyzer. To enable or disable verbose mode, use the following commands:

```
alt_signaltap_run('VERBOSE_ON');-alt_signaltap_run('VERBOSE_OFF');
```

When you finish acquiring data, close the JTAG connection with the following command:

```
alt_signaltap_run('END_CONNECTION');
```

For more information about the use of MATLAB MEX functions in MATLAB, refer to the MATLAB Help.

2.10. Signal Tap Logic Analyzer Design Examples

Application Note 845: Signal Tap Tutorial for Intel Arria 10 Partial Reconfiguration Design includes a design example that demonstrates Signal Tap debugging with a partial reconfiguration design. The design example has one 32-bit counter. At the board level, the design connects the clock to a 50MHz source, and connects the output to four LEDs on the FPGA. Selecting the output from the counter bits in a specific sequence causes the LEDs to blink at a specific frequency example demonstrates initiating a DMA transfer. The tutorial demonstrates how to tap signals in a PR design by extending the debug fabric to the PR regions when creating the base revision, and then defining debug components in the implementation revisions.

Application Note 446: Debugging Nios II Systems with the Signal Tap Logic Analyzer includes a design example with a Nios II processor, a direct memory access (DMA) controller, on-chip memory, and an interface to external SDRAM memory. After you press a button, the processor initiates a DMA transfer, which you analyze using the Signal Tap logic analyzer. In this example, the Nios II processor executes a simple C program from on-chip memory and waits for you to press a button.

- AN 446: Debugging Nios II Systems with the Signal Tap Logic Analyzer

2.11. Custom State-Based Triggering Flow Examples

The custom state-based triggering flow in the Signal Tap logic analyzer GUI can organize multiple triggering conditions for precise control over the acquisition buffer. The following examples demonstrate defining a custom triggering flow. You can easily copy the examples directly into the state machine description box by specifying the **All states in one window** option.

Related Information

On-chip Debugging Design Examples website

2.11.1. Trigger Example 1: Custom Trigger Position

Actions to the acquisition buffer can accept an optional post-count argument. This post-count argument enables you to define a custom triggering position for each segment in the acquisition buffer.

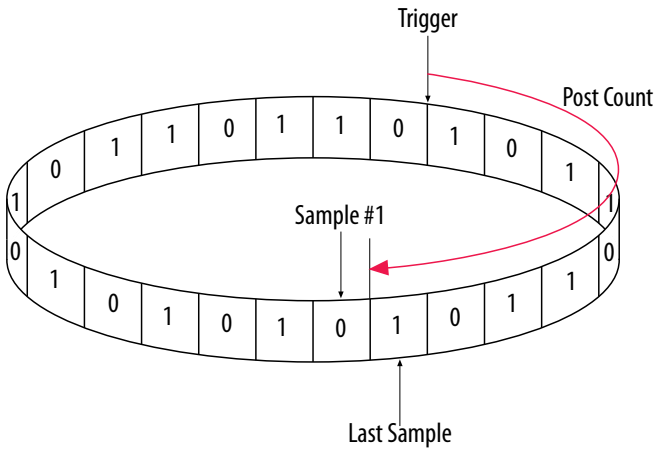
The following example shows how to apply a trigger position to all segments in the acquisition buffer. The example describes a triggering flow for an acquisition buffer split into four segments. If each acquisition segment is 64 samples in depth, the trigger position for each buffer is at sample #34. The acquisition stops after all segments are filled once.

```
if (c1 == 3 && condition1)
    trigger 30;
else if ( condition1 )
begin
    segment_trigger 30;
    increment c1;
end
```

Each segment acts as a non-segmented buffer that continuously updates the memory contents with the signal values.

The **Data** tab displays the last acquisition before stopping the buffer as the last sample number in the affected segment. The trigger position in the affected segment is then defined by *N* – `post count fill`, where *N* is the number of samples per segment.

Figure 94. Specifying a Custom Trigger Position



2.11.2. Trigger Example 2: Trigger When triggercond1 Occurs Ten Times between triggercond2 and triggercond3

You can use a custom trigger flow to count a sequence of events before triggering the acquisition buffer, as the following example shows. This example uses three basic triggering conditions configured in the Signal Tap **Setup** tab.

This example triggers the acquisition buffer when `condition1` occurs after `condition3` and occurs ten times prior to `condition3`. If `condition3` occurs prior to ten repetitions of `condition1`, the state machine transitions to a permanent wait state.

```
state ST1:
if ( condition2  )
begin
   reset c1;
   goto ST2;
end
```

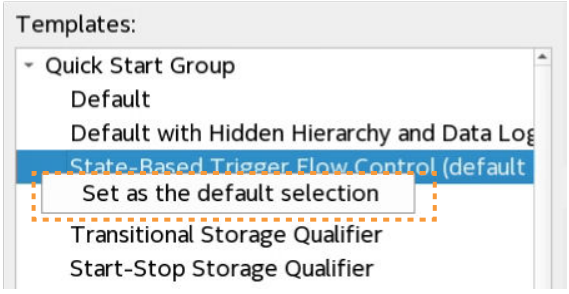
```
State ST2 :
if ( condition1 )
    increment c1;
else if (condition3 && c1 < 10)
    goto ST3;
else if ( condition3 && c1 >= 10)
    trigger;
ST3:
goto ST3;
```

2.12. Signal Tap File Templates

Signal Tap file templates provide preset settings for various trigger conditions, interfaces, and state-based triggering flows. The following Signal Tap file templates are available whenever you open a new Signal Tap session or create a new `.stp` file.

Right-click any template in the **New File from Template** dialog box, and then click **Set as the default selection** to always open new `.stp` files in that template by default.

Figure 95. Settings Default Signal Tap File Template



Note: Refer to the **New File from Template** dialog box for complete descriptions of all templates.

Table 26. Quick Start Signal Tap File Templates

Template	Summary Description
Default	The most basic and compact setup that is suitable for many debugging needs
Default with Hidden Hierarchy and Data Log	The same setup as the Default template, with additional Hierarchy Display and Data Log windows for trigger condition setup.
State-Based Trigger Flow Control	Starts with three conditions setup to replicate the basic sequential trigger flow control.
Conditional Storage Qualifier	Enables the **Conditional** storage qualifier and **Basic OR** condition. This setup provides a versatile storage qualifier condition expression.
Transitional Storage Qualifier	Enables the **Transitional** storage qualifier. The **Transitional** storage qualifier simply detects changes in data.
Start-Stop Storage Qualifier	Enables the **Start/Stop** storage qualifier and the **Basic OR** condition. Provides two conditions to frame the data.
State-Based Storage Qualifier	Provides more sophisticated qualification conditions for use with state machine expressions. You must use the State-Based Storage Qualifier template in conjunction with the state-based trigger flow control

continued...

Template	Summary Description
Input Port Storage Qualifier	Enables the **Input port** storage qualifier to provide total control of the storage qualifier condition by supporting development of custom logic outside of the Signal Tap logic hierarchy.
Trivial Advanced Trigger Condition	Enables the **Advanced** trigger condition. The **Advanced** condition provides the most flexibility to express complex conditions. The **Advanced** trigger condition scales from a simple wire to the most complex logical expression. This template starts with the simplest condition.
Trigger Position Defined Using Sample Count	Supports specifying an exact number of samples to store after the trigger position, using the **State-Based Trigger Flow Control** template as a reference.
Cross-triggering Between STP Instances	Enables "Cross-triggering by using the **Trigger out** from one instance as the **Trigger in** of another instance, when using multiple Signal Tap instances.
Setup for Incremental Compilation	Specifies a fixed input width for signal inputs. This technique allows efficient incremental compilation by reducing the amount of Signal Tap logic change, and by adding only post-fit nodes to tap.
Define Trigger Condition in RTL	Supports defining a custom trigger condition in the RTL language of your choice.

Table 27. Standard Interface Signal Tap File Templates

Template	Summary Description
Capture Avalon Memory Mapped Transactions	Allows you to use the storage qualifier feature to store only meaningful Avalon memory-mapped interface transactions.
Simple Avalon Streaming Interface Bus Performance Analysis	Supports recording of event time for analysis of the data packet flow in an Avalon streaming interface.
Use Counters in the State-based Flow Control to Collect Stats	Use counters to track of the number of packets produced (`pkt_counter`), number of data beats produced (`pkt_beat_counter`), and number of data beats consumed (`stream_beat_counter`).

Table 28. State-Based Triggering Design Flow Examples Signal Tap File Templates

Template	Setup Description
Trigger on an Event Absent for Greater Than or Equal to 5 Clock Cycles	Requires setup of one basic trigger condition in the **Setup** tab to the value that you want.
Trigger on Event Absent for Less Than 5 Clock Cycles	Requires setup of one basic trigger condition in the **Setup** tab to the value that you want.
Trigger on 5th Occurrence of a Group Value	Requires setup of one basic trigger condition in the **Setup** tab to the value that you want.
Trigger on the 5th Transition of a Group Value	Requires setup of an edge-sensitive trigger condition to detect all bus transitions to the desired group value. Requires edge detection for any data bus bit logically ANDed with a comparison to the desired group value. An advanced trigger condition is necessary in this case.
Trigger After Condition1 is Followed by Condition2	Requires setup of three basic trigger conditions in the **Setup** tab to the values you specify. The first two trigger conditions are set to the desired group values. The third trigger condition is set to capture some type of idle transaction across the bus between the first and second conditions.
Trigger on Condition1 Immediately Followed by Condition2	Requires setup of two basic trigger conditions in the **Setup** tab to the group values that you want.
Trigger on Condition2 Not Occurring Between Condition1 and Condition3	Requires setup of three basic trigger conditions in the **Setup** tab to the group values that you want.

continued...

Template	Setup Description
Trigger on the 5th Consecutive Occurrence of Condition1	Requires setup of one basic trigger condition in the **Setup** tab to the value you want.
Trigger After a Violation of Sequence From Condition1 To Condition4	Requires setup of four basic trigger conditions to the sequence values that you want.
Trigger on a Sequence of Edges	Requires setup of three edge-sensitive basic trigger conditions for the sequence that you want.
Trigger on Condition1 Followed by Condition2 After 5 Clock Cycles	Requires setup of two basic trigger conditions to the group values that you want.
Trigger on Condition1 Followed by Condition2 Within 5 Samples	Requires setup of two basic trigger conditions to the group values that you want.
Trigger on Condition1 Not Followed by Condition2 Within 5 Samples	Requires setup of two basic trigger conditions to the group values that you want.
Trigger After 5 Consecutive Transitions	Requires setup of a trigger condition to capture any transition activity on the monitored bus. This example requires an Advanced trigger condition because the example requires an OR condition.
Trigger When Condition1 Occurs Less Than 5 Times Between Condition2 and Condition3	Requires setup of three edge-sensitive trigger conditions, with each trigger condition containing a comparison to the desired group value.

2.13. Running the Stand-Alone Version of Signal Tap

You can optionally install a stand-alone version of the Signal Tap logic analyzer, rather than using the Signal Tap logic analyzer integrated with the Intel Quartus Prime software.

The stand-alone version of Signal Tap is particularly useful in a lab environment that lacks a suitable workstation for a complete Intel Quartus Prime installation, or lacks a full Intel Quartus Prime software license.

The standalone version of the Signal Tap logic analyzer includes and requires use of the Intel Quartus Prime stand-alone Programmer, which is also available from the Download Center for FPGAs.

2.14. Signal Tap Scripting Support

The Intel Quartus Prime software supports automation of Signal Tap controls in a Tcl scripting environment, or with the `quartus_stp` executable. For detailed information about scripting command options, refer to the Intel Quartus Prime command-line and Tcl API help by typing `quartus_sh --qhelp` at the command prompt.

Related Information

Intel Quartus Prime Pro Edition User Guide: Scripting

2.14.1. Signal Tap Command-Line Options

You can use the following options with the `quartus_stp` executable:

Table 29. quartus_stp Command-Line Options

Option	Usage	Description
`--stp_file <stp_filename>`	Required	Specifies the name of the `.stp` file.
`--enable`	Optional	Sets the `ENABLE_SIGNALTAP` option to `ON` in the project's `.qsf` file, so the Signal Tap logic analyzer runs in the next compilation. If you omit this option, the Intel Quartus Prime software uses the current value of `ENABLE_SIGNALTAP` in the `.qsf` file. Writes subsequent Signal Tap assignments to the `.stp` that appears in the `.qsf` file. If the `.qsf` file does not specify a `.stp` file, you must use the `--stp_file` option.
`--disable`	Optional	Sets the `ENABLE_SIGNALTAP` option to `OFF` in the project's `.qsf` file, so the Signal Tap logic analyzer does not in the next compilation. If you omit the `--disable` option, the Intel Quartus Prime software uses the current value of `ENABLE_SIGNALTAP` in the `.qsf` file.

2.14.2. Data Capture from the Command Line

The `quartus_stp` executable supports a Tcl interface that allows you to capture data without running the Intel Quartus Prime GUI.

Note: You cannot execute Signal Tap Tcl commands from within the Tcl console in the Intel Quartus Prime software.

To execute a Tcl script containing Signal Tap logic analyzer Tcl commands, use:

```
quartus_stp -t <Tcl file>
```

Example 2. Continuously Capturing Data

This excerpt shows commands you can use to continuously capture data. Once the capture meets trigger condition, the Signal Tap logic analyzer starts the capture and stores the data in the data log.

```
#  Open Signal Tap session
open_session -name stp1.stp

###  Start acquisition of instances auto_signaltap_0 and
###  auto_signaltap_1 at the same time

# Calling run_multiple_end starts all instances
run_multiple_start

run -instance auto_signaltap_0 -signal_set signal_set_1 -trigger \
     trigger_1 -data_log log_1 -timeout 5
run -instance auto_signaltap_1 -signal_set signal_set_1 -trigger \
     trigger_1 -data_log log_1 -timeout 5

run_multiple_end

# Close Signal Tap session
close_session
```

Related Information

::quartus::stp
In *Intel Quartus Prime Help*

2.15. Signal Tap File Version Compatibility

If you open a `.stp` file created in a previous version of the Intel Quartus Prime software in a newer version of the software, you can no longer open that `.stp` file in the previous version of the Intel Quartus Prime software.

If you open an Intel Quartus Prime project that includes a `.stp` file from a previous version of the software in a later version of the Intel Quartus Prime software, the software may require you to update the `.stp` configuration file before you can compile the project. Update the configuration file by simply opening the `.stp` in the Signal Tap logic analyzer GUI. If configuration update is required, Signal Tap confirms that you want to update the `.stp` to match the current version of the Intel Quartus Prime software.

Note: The Intel Quartus Prime Pro Edition software uses a new methodology for settings and assignments. For example, Signal Tap assignments include only the `instance` name, not the `entity:instance` name. Refer to *Migrating to Intel Quartus Prime Pro Edition* for more information about migrating existing Signal Tap files (`.stp`) to Intel Quartus Prime Pro Edition.

2.16. Design Debugging with the Signal Tap Logic Analyzer Revision History

The following revision history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.12.04	23.4	• Added support for != operator to *Comparison Trigger Conditions* topic.
2023.10.02	23.3	• Enhanced the information in *Enabling a Power-Up Trigger*. • Made a minor correction in the image in *Specifying the Buffer Acquisition Mode*. • Made a minor correction in the description in *Managing Signal Tap Instances with Run-Time and Power-Up Trigger Conditions*.
2022.07.08	22.1	• Fixed broken link in *Custom State-Based Triggering Flow Examples*.
2022.03.28	22.1	• Added *Organizing Signals in the Signal Tap Logic Analyzer* topic. • Removed incorrect links from *Intel Quartus Prime Pro Edition User Guide Debug Tools Archives* topic.
2021.10.13	21.3	• Added *Recompiling Only Signal Tap Changes* topic. • Changed title of *Prevent Changes Requiring Recompilation* to *Preventing Changes that Require Full Recompilation* and revised figures.

continued...

Document Version	Intel Quartus Prime Version	Changes
2021.10.04	21.3	• Updated *Signal Tap Logic Analyzer Introduction* with *Signal Tap Logic Analyzer and Simulator Integration* section. • Added description of Autorun mode to *Managing Signal Tap Instances* topic. • Added new *Adding Simulator-Aware Signal Tap Nodes* topic. • Added new *Add Simulator Aware Node Finder Settings* topic. • Added new *Signal Tap and Simulator Integration* topic. • Added new *Generating a Simulation Testbench from Signal Tap Data* topic. • Added new *Create Simulation Testbench Dialog Box Settings* topic. • Revised *Preserving Signals for Monitoring and Debugging* topic for latest techniques and links to other resources. • Revised *Adding Pre-Synthesis or Post-Fit Nodes* for latest techniques and links to other resources. • Added new *Changing the Post-Fit Signal Tap Target Nodes* topic. • Updated *Adding Pre-Synthesis or Post-Fit Nodes* topic for preserve for debug filters. • Added details about SOF Manager to *Ensure Compatibility Between .stp and .sof Files* topic.
2020.09.28	20.3	• Revised "Signal Tap Logic Analyzer Introduction" for screenshot and details about role of Signal Tap Intel FPGA IP. • Revised graphic and wording in "Signal Tap Hardware and Software Requirements" topic. • Revised wording and link to download in "Running the Stand-Alone Version of Signal Tap." • Updated flow diagram and added links to retitled "Signal Tap Debugging Flow" topic. • Retitled "Add the Signal Tap Logic Analyzer to Your Design" to "Step 1: Add the Signal Tap Logic Analyzer to the Project," and referenced new template and added links to next steps. • Added "Creating a Signal Tap Instance with the Signal Tap GUI" topic. • Added new "Signal Tap File Templates" topic. • Added new "Creating a Signal Tap Instance by HDL Instantiation" topic. • Added new "Signal Tap Intel FPGA IP Parameters" topic. • Retitled "Configure the Signal Tap Logic Analyzer" to "Step 2: Configure the Signal Tap Logic Analyzer," and referenced new template and added links to next steps. • Enhanced description in Step 5: Run the Signal Tap Logic Analyzer" topic. • Revised "Adding Signals to the Signal Tap Logic Analyzer" to add detailed steps and screenshot. • Retitled and revised "Adding Nios II Processor Signals" to reflect there is only one plug-in in Intel Quartus Prime Pro Edition. • Revised "Disabling or Enabling Signal Tap Instances" and added screenshot. • Replaced outdated links to AN446 with links to AN845. • Revised headings and steps in "Debugging Block-Based Designs with Signal Tap" section. • Retitled "Debugging Imported Snapshots" to "Compiler Snapshots and Signal Tap Debugging". • Retitled "Backward Compatibility" to "Signal Tap File Version Compatibility." • Removed incorrect statement about debugging multiple designs from "Step 4: Program the Target Hardware" topic.

continued...

Document Version	Intel Quartus Prime Version	Changes
		• Removed reference to obsolete resource checking function from "Ensure Compatibility Between STP and SOF Files" topic. • Removed obsolete "Remote Debugging Using the Signal Tap Logic Analyzer" section. • Removed obsolete "Estimating FPGA Resources" topic.
2019.06.11	18.1.0	Added more explanation to Comparing Continuous and Input Port Capture Mode in Data Acquisition of a Recurring Data Pattern about continuous and input mode.
2019.05.01	18.1.0	In *Adding Signals with a Plug-In* topic, removed outdated information from step 1 about turning on **Create debugging nodes for IP cores**.
2018.09.24	18.1.0	• Added content about debugging designs in block-based flows. • Renamed topic: *Untappable Signals* to *Signals Unavailable for Signal Tap Debugging*.
2018.08.07	18.0.0	Reverted document title to *Debug Tools User Guide: Intel Quartus Prime Pro Edition*.
2018.07.30	18.0.0	Updated Partial Reconfiguration sections to reflect changes in the PR flow.
2018.05.07	18.0.0	• Added note stating Signal Tap IP not optimized for Stratix 10 Devices. • Moved information about debug fabric on PR designs to the *System Debugging Tools Overview* chapter. • Removed restrictions of Rapid Recompile support for Intel Stratix 10 devices.
2017.11.06	17.1.0	• Added support for Incremental Routing in Intel Stratix 10 devices. • Removed unsupported FSM auto detection. • Clarified information about the Data Log Pane. • Updated Figure: Data Log and renamed to Simple Data Log. • Added Figure: Accessing the Advanced Trigger Condition Tab. • Removed outdated information about command-line flow.
2017.05.08	17.0.0	• Added: Open Standalone Signal Tap Logic Analyzer GUI. • Added: Debugging Partial Reconfiguration Designs Using Signal Tap Logic Analyzer. • Updated figures on Create Signal Tap File from Design Instance(s).
2016.10.31	16.1.0	• Implemented Intel rebranding. • Added: Create SignalTap II File from Design Instance(s). • Removed reference to unsupported Talkback feature.
2016.05.03	16.0.0	• Added: Specifying the Pipeline Factor • Added: Comparison Trigger Conditions
2015.11.02	15.1.0	• Changed instances of *Quartus II* to *Intel Quartus Prime*. • Updated content to reflect SignalTap II support in Intel Quartus Prime Pro Edition
2015.05.04	15.0.0	Added content for Floating Point Display Format in table: SignalTap II Logic Analyzer Features and Benefits.
2014.12.15	14.1.0	Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Synthesis Optimizations to Compiler Settings.
December 2014	14.1.0	• Added MAX 10 as supported device. • Removed Full Incremental Compilation setting and Post-Fit (Strict) netlist type setting information. • Removed outdated GUI images from "Using Incremental Compilation with the SignalTap II Logic Analyzer" section.

continued...

Document Version	Intel Quartus Prime Version	Changes
June 2014	14.0.0	• DITA conversion. • Replaced MegaWizard Plug-In Manager and Megafunction content with IP Catalog and parameter editor content. • Added flows for custom trigger HDL object, Incremental Route with Rapid Recompile, and nested groups with Basic OR. • GUI changes: toolbar, drag to zoom, disable/enable instance, trigger log time-stamping.
November 2013	13.1.0	Removed HardCopy material. Added section on using cross-triggering with DS-5 tool and added link to white paper 01198. Added section on remote debugging an Altera SoC and added link to application note 693. Updated support for MEX function.
May 2013	13.0.0	• Added recommendation to use the state-based flow for segmented buffers with separate trigger conditions, information about Basic OR trigger condition, and hard processor system (HPS) external triggers. • Updated "Segmented Buffer" on page 13-17, Conditional Mode on page 13-21, Creating Basic Trigger Conditions on page 13-16, and Using External Triggers on page 13-48.
June 2012	12.0.0	Updated Figure 13–5 on page 13–16 and "Adding Signals to the SignalTap II File" on page 13–10.
November 2011	11.0.1	Template update. Minor editorial updates.
May 2011	11.0.0	Updated the requirement for the standalone SignalTap II software.
December 2010	10.0.1	Changed to new document template.
July 2010	10.0.0	• Add new acquisition buffer content to the "View, Analyze, and Use Captured Data" section. • Added script sample for generating hexadecimal CRC values in programmed devices. • Created cross references to Quartus II Help for duplicated procedural content.
November 2009	9.1.0	No change to content.
March 2009	9.0.0	• Updated Table 13–1 • Updated "Using Incremental Compilation with the SignalTap II Logic Analyzer" on page 13–45 • Added new Figure 13–33 • Made minor editorial updates
November 2008	8.1.0	Updated for the Quartus II software version 8.1 release: • Added new section "Using the Storage Qualifier Feature" on page 14–25 • Added description of `start_store` and `stop_store` commands in section "Trigger Condition Flow Control" on page 14–36 • Added new section "Runtime Reconfigurable Options" on page 14–63
May 2008	8.0.0	Updated for the Quartus II software version 8.0: • Added "Debugging Finite State machines" on page 14-24 • Documented various GUI usability enhancements, including improvements to the resource estimator, the bus find feature, and the dynamic display updates to the counter and flag resources in the State-based trigger flow control tab • Added "Capturing Data Using Segmented Buffers" on page 14–16 • Added hyperlinks to referenced documents throughout the chapter • Minor editorial updates

3. Quick Design Verification with Signal Probe

This chapter describes a technique that provides debug access to internal device signals without affecting the design.

The Signal Probe feature in the Intel Quartus Prime Pro Edition software allows you to route an internal node to a top-level I/O. When you start with a fully routed design, you can select and route debugging signals to I/O pins that you previously reserve or are currently unused.

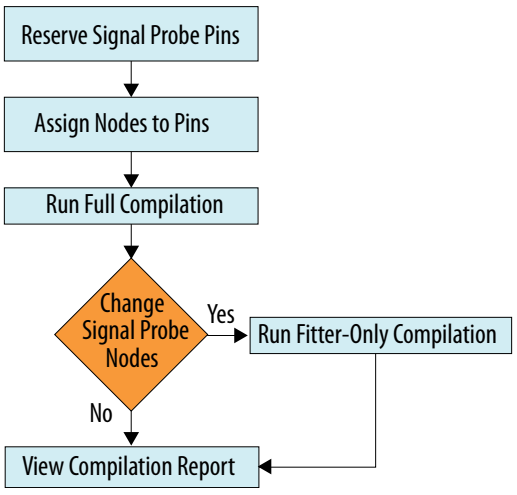
Related Information

System Debugging Tools Overview on page 6

3.1. Signal Probe Debugging Flow

Use the following flow to add Signal Probe debugging and verification capabilities to your design:

Figure 96. Signal Probe Debugging Flow



Step 1: Reserve Signal Probe Pins on page 125
Step 2: Assign Nodes to Signal Probe Pins on page 125
Step 3: Connect the Signal Probe Pin to an Output Pin on page 125
Step 4: Compile the Design on page 126
(Optional) Step 5: Modify the Signal Probe Pins Assignments on page 126
Step 6: Run Fitter-Only Compilation on page 126
Step 7: Check Connection Table in Fitter Report on page 127

3.1.1. Step 1: Reserve Signal Probe Pins

You must first create and reserve a pin for Signal Probe with a Tcl command:

```
set_global_assignment –name CREATE_SIGNALPROBE_PIN <pin_name>
```

pin_name Specifies the name of the Signal Probe pin.

Optionally, you can assign locations for the Signal Probe pins. If you do not assign a location, the Fitter places the pins automatically.

Note: If from the onset of the debugging process you know which internal signals you want to route, you can reserve pins and assign nodes before compilation. This early assignment removes the recompilation step from the flow.

Example 3. Tcl Command to Reserve Signal Probe Pins

```
set_global_assignment -name CREATE_SIGNALPROBE_PIN wizard
set_global_assignment -name CREATE_SIGNALPROBE_PIN probey
```

Related Information

Constraining Designs with Tcl Scripts

3.1.2. Step 2: Assign Nodes to Signal Probe Pins

You can assign any node in the post-compilation netlist to a Signal Probe pin. In the Intel Quartus Prime software, click **View ➤ Node Finder**, and filter by **Signal Tap: post-fitting** to view the nodes you can route.

You specify the node that connects to a Signal Probe pin with a Tcl command:

```
set_instance_assignment –name CONNECT_SIGNALPROBE_PIN <pin_name> \
     –to <node_name>
```

pin_name Specifies the name of the Signal Probe pin that connects to the node.

node_name Specifies the full hierarchy path of the node you want to route.

Example 4. Tcl Commands to Connect Pins to Internal Nodes

```
# Make assignments to connect nodes of interest to pins
set_instance_assignment -name CONNECT_SIGNALPROBE_PIN wizard -to sprobe_me1
set_instance_assignment -name CONNECT_SIGNALPROBE_PIN probey -to sprobe_me2
```

3.1.3. Step 3: Connect the Signal Probe Pin to an Output Pin

Once you reserve pins and assign internal nodes to the Signal Probe pins, you must connect the Signal Probe pin to an external output pin.

Example 5. Tcl Command to Specify Signal Probe Pin Assignment

```
set_instance_assignment –name CONNECT_SIGNALPROBE_PIN <pin_name> –to <node_name>
```

3.1.4. Step 4: Compile the Design

Perform a full compilation of the design. You can use Intel Quartus Prime software GUI, a command line executable, or the following Tcl command to start the Compiler

Example 6. Tcl Command to Compile the Design

```
execute_flow -compile
```

At this point in the design flow, you can determine the nodes that you want to debug.

Related Information

Design Compilation

3.1.5. (Optional) Step 5: Modify the Signal Probe Pins Assignments

As long as you reserve the pins (with CREATE_SIGNALPROBE_PIN) before running full compilation, you can optionally add or modify the node that connects to a reserved Signal Probe pin (with CONNECT_SIGNALPROBE_PIN) without rerunning a full compilation. Rather, you can run a Fitter-only compilation to implement the Signal Probe pin assignment change.

Note: If you modify the physical I/O pin assignments with (with CREATE_SIGNALPROBE_PIN) after running compilation, you must rerun full compilation to implement those changes before using Signal Probe.

Example 7. Tcl Command to Specify Signal Probe Pin Assignment

```
set_instance_assignment –name CONNECT_SIGNALPROBE_PIN <pin_name> –to <node_name>
```

3.1.6. Step 6: Run Fitter-Only Compilation

After re-assigning nodes to the Signal Probe pins, you can run a Fitter-only compilation (using `--recompile`) to implement the post-fit change without rerunning a full compilation.

Example 8. Tcl Command to Run Fitter-Only Compile

```
# Run the fitter with --recompile to preserve timing
# and quickly connect the Signal Probe pins
execute_module -tool fit -args {--recompile}
```

After recompilation, you are ready to program the device and debug the design.

Related Information

- Using the ECO Compilation Flow in *Intel Quartus Prime Pro Edition User Guide: Design Optimization*
- Using the ECO Compilation Flow in *Intel Quartus Prime Pro Edition User Guide: Design Optimization*

3.1.7. Step 7: Check Connection Table in Fitter Report

When you compile a design with Signal Probe pins, Compiler generates a connection report showing the connection status to Signal Probe pins.

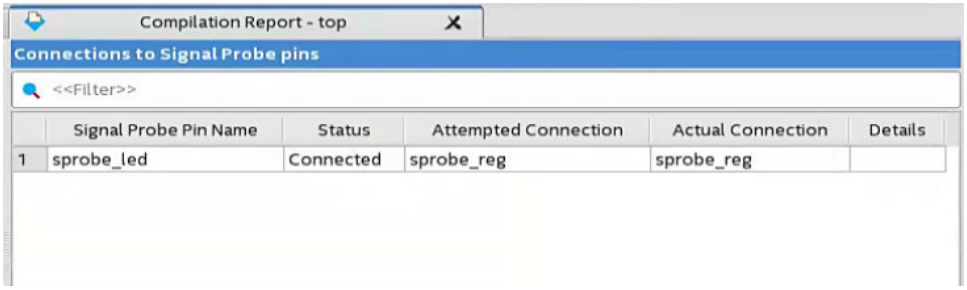
To view this report, click **Processing ➤ Compilation Report**, open the **Fitter ➤ In-System Debugging** folder, and click **Connections to Signal Probe pins**.

The **Status** column indicates whether or not the routing attempt from the nodes to the Signal Probe pins is successful.

Table 30. Status of Signal Probe Connection

Status	Description
Connected	Routing succeeded.
Unconnected	Routing did not succeed. Possible reasons are: • Node belongs to an I/O cell or another hard IP, thus cannot be routed. • Node hierarchy path does not exist in the design. • Node is not **Signal Tap: post-fitting**.

Example 9. Connections to Signal Probe Pins in the Compilation Report



Alternatively, you can find the Signal Probe connection information in the Fitter report file (<*project_name*>.fit.rpt).

Example 10. Connections to Signal Probe Pins in top.fit.rpt

```
+----------------------------------------------------------------------------
+
; Connections to Signal Probe
pins                                                ;

3.2. Quick Design Verification with Signal Probe Revision History

Document Version	Intel Quartus Prime Version	Changes
2021.10.04	21.3	• Removed references to obsolete Rapid Recompile feature. • Updated *Signal Probe Debugging Flow* topic for new optional step and added flow diagram. • Added step numbers to tasks in flow to emphasize order of operations. • Added *(Optional) Step 4: Modify the Signal Probe Pins Assignments* topic. • Revised wording in *Step 5: Run Fitter-Only Compilation*. • Revised screenshot and wording in *Step 6: Check Connection Table in Fitter Report*. • Added new *Step 3: Connect the Signal Probe Pin to an Output Pin* topic.
2018.05.07	18.0.0	Initial release for Intel Quartus Prime Pro Edition software.

4. In-System Debugging Using External Logic Analyzers

4.1. About the Intel Quartus Prime Logic Analyzer Interface

The Intel Quartus Prime Logic Analyzer Interface (LAI) allows you to use an external logic analyzer and a minimal number of Intel-supported device I/O pins to examine the behavior of internal signals while your design is running at full speed on your Intel-supported device.

The LAI connects a large set of internal device signals to a small number of output pins. You can connect these output pins to an external logic analyzer for debugging purposes. In the Intel Quartus Prime LAI, the internal signals are grouped together, distributed to a user-configurable multiplexer, and then output to available I/O pins on your Intel-supported device. Instead of having a one-to-one relationship between internal signals and output pins, the Intel Quartus Prime LAI enables you to map many internal signals to a smaller number of output pins. The exact number of internal signals that you can map to an output pin varies based on the multiplexer settings in the Intel Quartus Prime LAI.

Note: The term "logic analyzer" when used in this document includes both logic analyzers and oscilloscopes equipped with digital channels, commonly referred to as mixed signal analyzers or MSOs.

The LAI does not support Hard Processor System (HPS) I/Os.

Related Information

Devices Support Center

4.2. Choosing a Logic Analyzer

The Intel Quartus Prime software offers the following two general purpose on-chip debugging tools for debugging a large set of RTL signals from your design:

- The Signal Tap Logic Analyzer
- An external logic analyzer, which connects to internal signals in your Intel-supported device by using the Intel Quartus Prime LAI

Table 31. Comparing the Signal Tap Logic Analyzer with the Logic Analyzer Interface

Feature	Description	Recommended Logic Analyzer
Sample Depth	You have access to a wider sample depth with an external logic analyzer. In the Signal Tap Logic Analyzer, the maximum sample depth is set to	LAI

continued...

Feature	Description	Recommended Logic Analyzer
	128 Kb, which is a device constraint. However, with an external logic analyzer, there are no device constraints, providing you a wider sample depth.	
Debugging Timing Issues	Using an external logic analyzer provides you with access to a "timing" mode, which enables you to debug combined streams of data.	LAI
Performance	You frequently have limited routing resources available to place and route when you use the Signal Tap Logic Analyzer with your design. An external logic analyzer adds minimal logic, which removes resource limits on place-and-route.	LAI
Triggering Capability	The Signal Tap Logic Analyzer offers triggering capabilities that are comparable to external logic analyzers.	LAI or Signal Tap
Use of Output Pins	Using the Signal Tap Logic Analyzer, no additional output pins are required. Using an external logic analyzer requires the use of additional output pins.	Signal Tap
Acquisition Speed	With the Signal Tap Logic Analyzer, you can acquire data at speeds of over 200 MHz. You can achieve the same acquisition speeds with an external logic analyzer; however, you must consider signal integrity issues.	Signal Tap

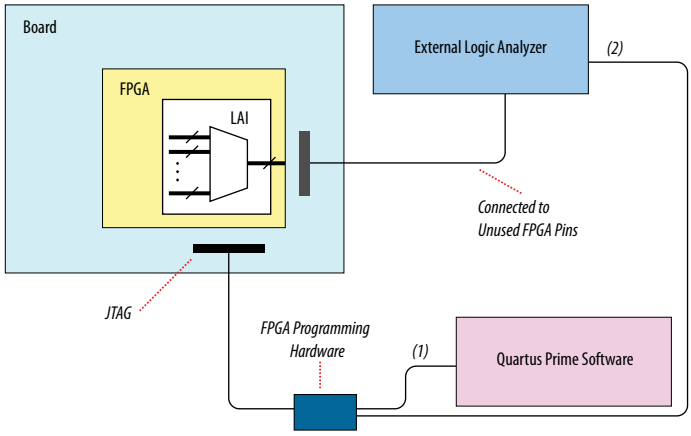
System Debugging Tools Overview on page 6

4.2.1. Required Components

To perform analysis using the LAI you need the following components:

- Intel Quartus Prime software version 15.1 or later
- The device under test
- An external logic analyzer
- An Intel FPGA communications cable
- A cable to connect the Intel-supported device to the external logic analyzer

Figure 97. LAI and Hardware Setup

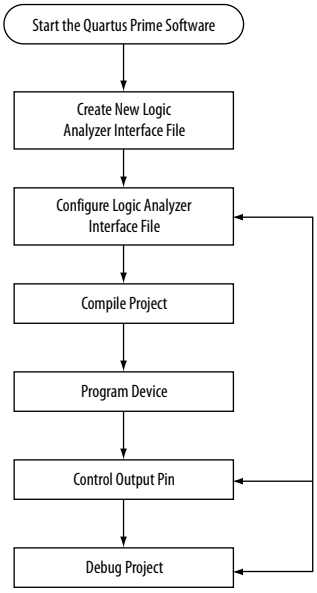


Notes to figure:

1. Configuration and control of the LAI using a computer loaded with the Intel Quartus Prime software via the JTAG port.
2. Configuration and control of the LAI using a third-party vendor logic analyzer via unused FPGA pins. Support varies by vendor.

4.3. Flow for Using the LAI

Figure 98. LAI Workflow

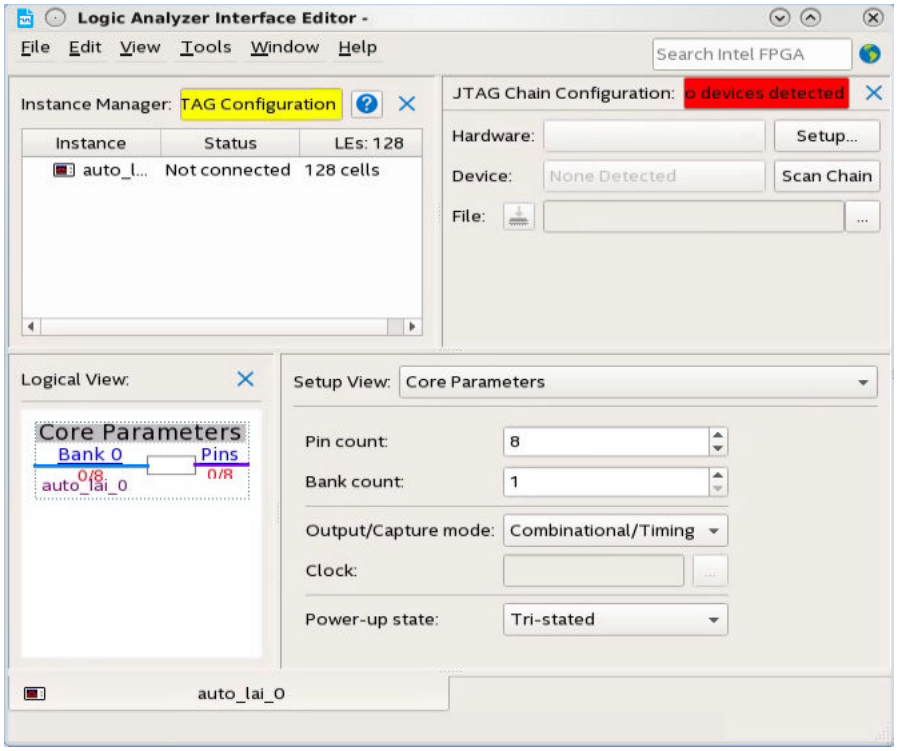


4.3.1. Defining Parameters for the Logic Analyzer Interface

The **Logic Analyzer Interface Editor** allows you to define the parameters of the LAI.

- Click **Tools ➤ Logic Analyzer Interface Editor**.

Figure 99. Logic Analyzer Interface Editor



- In the **Setup View** list, select **Core Parameters**.
- Specify the parameters of the LAI instance.

Related Information

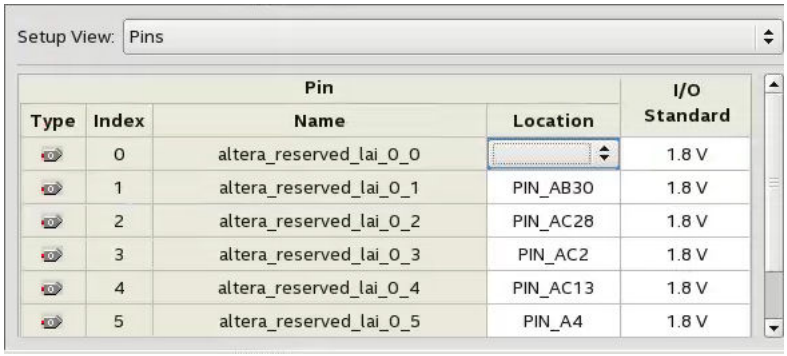
LAI Core Parameters on page 135

4.3.2. Mapping the LAI File Pins to Available I/O Pins

To assign pin locations for the LAI:

1. Select **Pins** in the **Setup View** list

Figure 100. Mapping LAI file Pins



2. Double-click the **Location** column next to the reserved pins in the **Name** column, and select a pin from the list.
3. Right-click the selected pin and locate in the Pin Planner.

Related Information

Managing Device I/O Pins
In *Intel Quartus Prime Pro Edition User Guide: Design Constraints*

4.3.3. Mapping Internal Signals to the LAI Banks

After specifying the number of banks to use in the **Core Parameters** settings page, you must assign internal signals for each bank in the LAI.

1. Click the **Setup View** arrow and select **Bank n** or **All Banks**.
2. To view all the bank connections, click **Setup View** and then select **All Banks**.
3. Before making bank assignments, right click the Node list and select **Add Nodes** to open the **Node Finder**.
4. Find the signals that you want to acquire.
5. Drag the signals from the **Node Finder** dialog box into the bank **Setup View**.

   When adding signals, use **Signal Tap: pre-synthesis** for non-incrementally routed instances and **Signal Tap: post-fitting** for incrementally routed instances

   As you continue to make assignments in the bank **Setup View**, the schematic of the LAI in the **Logical View** pane begins to reflect the changes.
6. Continue making assignments for each bank in the **Setup View** until you add all the internal signals that you want to acquire.

Related Information

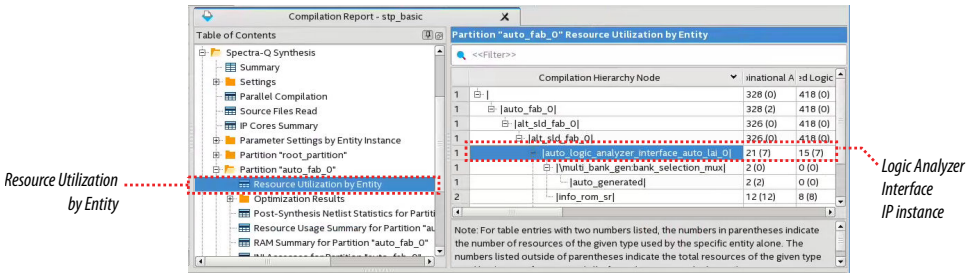
Node Finder Command
In *Intel Quartus Prime Help*

4.3.4. Compiling Your Intel Quartus Prime Project

After you save your `.lai` file, a dialog box prompts you to enable the Logic Analyzer Interface instance for the active project. Alternatively, you can define the `.lai` file your project uses in the **Global Project Settings** dialog box. After specifying the name of your `.lai` file, compile your project.

To verify the Logic Analyzer Interface is properly compiled with your project, open the **Compilation Report** tab and select Resource Utilization by Entity, nested under Partition "auto_fab_0". The LAI IP instance appears in the Compilation Hierarchy Node column, nested under the internal module of `auto_fab_0`

Figure 101. LAI Instance in Compilation Report



4.3.5. Programming Your Intel-Supported Device Using the LAI

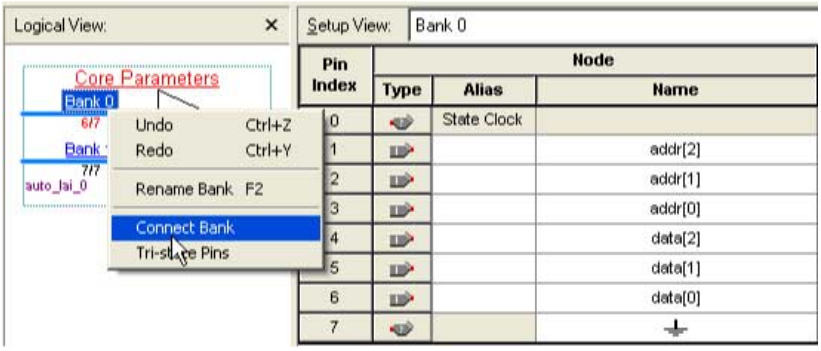
After compilation completes, you must configure your Intel-supported device before using the LAI.

You can use the LAI with multiple devices in your JTAG chain. Your JTAG chain can also consist of devices that do not support the LAI or non-Intel, JTAG-compliant devices. To use the LAI in more than one Intel-supported device, create an `.lai` file and configure an `.lai` file for each Intel-supported device that you want to analyze.

4.4. Controlling the Active Bank During Runtime

When you have programmed your Intel-supported device, you can control which bank you map to the reserved `.lai` file output pins. To control which bank you map, in the schematic in the Logical View, right-click the bank and click **Connect Bank**.

Figure 102. Configuring Banks



4.4.1. Acquiring Data on Your Logic Analyzer

To acquire data on your logic analyzer, you must establish a connection between your device and the external logic analyzer. For more information about this process and for guidelines about how to establish connections between debugging headers and logic analyzers, refer to the documentation for your logic analyzer.

4.5. LAI Core Parameters

The table lists the LAI file core parameters:

Table 32. LAI File Core Parameters

Parameter	Range Value	Description
Pin Count	1 - 255	Number of pins dedicated to the LAI. You must connect the pins to a debug header on the board. Within the device, The Compiler maps each pin to a user-configurable number of internal signals.
Bank Count	1 - 255	Number of internal signals that you want to map to each pin. For example, a **Bank Count** of 8 implies that you connect eight internal signals to each pin.
Output/Capture Mode		Specifies the acquisition mode. The two options are: • **Combinational/Timing**—This acquisition mode uses the external logic analyzer's internal clock to determine when to sample data. This acquisition mode requires you to manually determine the sample frequency to debug and verify the system, because the data sampling is asynchronous to the Intel-supported device. This mode is effective if you want to measure timing information such as channel-to-channel skew. For more information about the sampling frequency and the speeds at which it can run, refer to the external logic analyzer's data sheet. • **Registered/State**—This acquisition mode determines when to sample from a signal on the system under test. Consequently, the data samples are synchronous with the Intel-supported device. The **Registered/State** mode provides a functional view of the Intel-supported device while it is running. This mode is effective when you verify the functionality of the design.
Clock		Specifies the sample clock. You can use any signal in the design as a sample clock. However, for best results, use a clock with an operating frequency fast enough to sample the data that you want to acquire. *Note:* The **Clock** parameter is available only when **Output/Capture Mode** is set to **Registered State**.
Power-Up State		Specifies the power-up state of the pins designated for use with the LAI. You can select tri-stated for all pins, or selecting a particular bank that you enable.

4.6. In-System Debugging Using External Logic Analyzers Revision History

The following revision history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.10.02	23.3	• Made a minor correction in the description in *Required Components*. • Removed the figure notes in *Flow for Using the LAI*.
2022.07.08	22.1	• Fixed broken link in "About the Intel Quartus Prime Logic Analyzer Interface"

continued...

Document Version	Intel Quartus Prime Version	Changes
2018.05.07	18.0.0	• Moved list of LAI File Core Parameters from *Configuring the File Core Parameters* to its own topic, and added links.
2017.05.08	17.0.0	• Updated *Compiling Your Intel Quartus Prime Project* • Updated figure: LAI Instance in Compilation Report.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2015.11.02	15.1.0	Changed instances of *Quartus II* to *Intel Quartus Prime*.
June 2014	14.0.0	• Dita conversion • Added limitation about HPS I/O support
June 2012	12.0.0	Removed survey link
November 2011	10.1.1	Changed to new document template
December 2010	10.1.0	• Minor editorial updates • Changed to new document template
August 2010	10.0.1	Corrected links
July 2010	10.0.0	• Created links to the Intel Quartus Prime Help • Editorial updates • Removed Referenced Documents section
November 2009	9.1.0	• Removed references to APEX devices • Editorial updates
March 2009	9.0.0	• Minor editorial updates • Removed Figures 15–4, 15–5, and 15–11 from 8.1 version
November 2008	8.1.0	Changed to 8-1/2 x 11 page size. No change to content
May 2008	8.0.0	• Updated device support list on page 15–3 • Added links to referenced documents throughout the chapter • Added "Referenced Documents" • Added reference to *Section V. In-System Debugging* • Minor editorial updates

5. In-System Modification of Memory and Constants

The Intel Quartus Prime In-System Memory Content Editor (ISMCE) allows to view and update memories and constants at runtime through the JTAG interface. By testing changes to memory contents in the FPGA while the design is running, you can identify, test, and resolve issues.

The ability to read data from memories and constants can help you identify the source of problems, and the write capability allows you to bypass functional issues by writing expected data.

When you use the In-System Memory Content Editor in conjunction with the Signal Tap logic analyzer, you can view and debug your design in the hardware lab.

Related Information

- System Debugging Tools Overview on page 6
- Design Debugging with the Signal Tap Logic Analyzer on page 29

5.1. IP Cores Supporting In System Memory Content Editor

You can use the In System Memory Content Editor (ISMCE) with the following Intel FPGA IP cores in the current version of the Intel Quartus Prime Pro Edition software:

Table 33. IP Cores Supporting ISMCE

Device Family	IP Supported for ISMCE
Intel Agilex® 7 devices Intel Stratix 10 devices Intel Cyclone® 10 GX devices Intel Arria 10 devices	• RAM: 1-PORT Intel FPGA IP • ROM: 1-PORT Intel FPGA IP

Note: To use the ISMCE tool with designs migrated from an older device to the Intel Stratix 10 device or the Intel Agilex 7 device, you must first replace instances of the altsyncram Intel FPGA IP with the altera_syncram Intel FPGA IP.

Related Information

  In *Embedded Memory (RAM: 1-PORT, RAM: 2-PORT, ROM: 1-PORT, and ROM: 2-PORT) User Guide*
- Intel Agilex 7 Embedded Memory User Guide

5.2. Debug Flow with the In-System Memory Content Editor

To debug a design with the In-System Memory Content Editor:

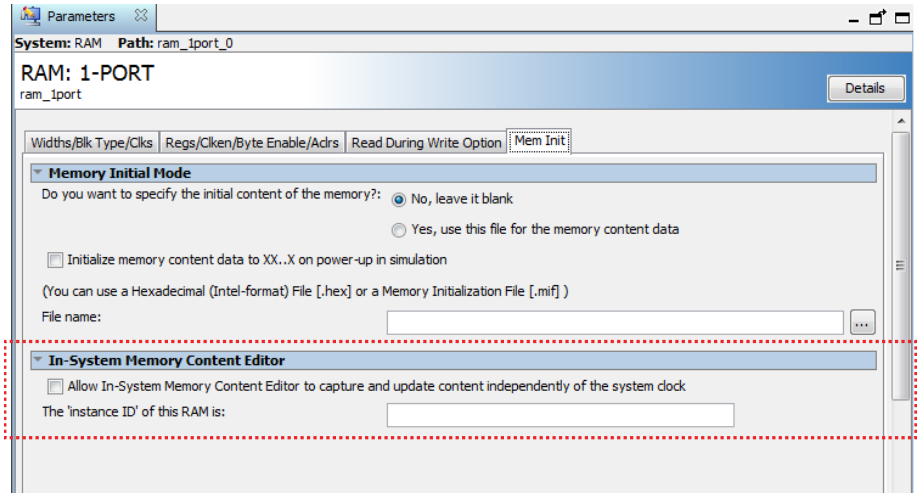
1. Identify the memories and constants that you want to access at runtime.
2. Specify in the design the memory or constant that must be run-time modifiable.
3. Perform a full compilation.
4. Program the device.
5. Launch the In-System Memory Content Editor.
   The In-System Memory Content Editor retrieves all instances of run-time configurable memories and constants by scanning the JTAG chain and sending a query to the device selected in the JTAG Chain Configuration pane.
6. Modify the values of the memories or constants, and check the results.

   For example, if a parity bit in a memory is incorrect, you can use the In-System Memory Content Editor to write the correct parity bit values into the RAM, allowing the system to continue functioning. To check the error handling functionality of a design, you can intentionally write incorrect parity bit values into the RAM.

5.3. Enabling Runtime Modification of Instances in the Design

To make an instance of a memory or constant runtime-modifiable:

1. Open the instance with the Parameter Editor.
2. In the Parameter Editor, turn on **Allow In-System Memory Content Editor to capture and update content independently of the system clock**.



3. Recompile the design.

When you specify that a memory or constant is run-time modifiable, the Intel Quartus Prime software changes the default implementation to enable run-time modification without changing the functionality of your design, by:

- Converting single-port RAMs to dual-port RAMs
- Adding logic to avoid memory write collision and maintain read write coherency in device families that do not support true dual-port RAMs, such as the Intel Stratix 10 device family.

5.4. Programming the Device with the In-System Memory Content Editor

After compilation, you must program the design in the FPGA. You can use the **JTAG Chain Configuration** pane to program the device from within the In-System Memory Content Editor.

Related Information

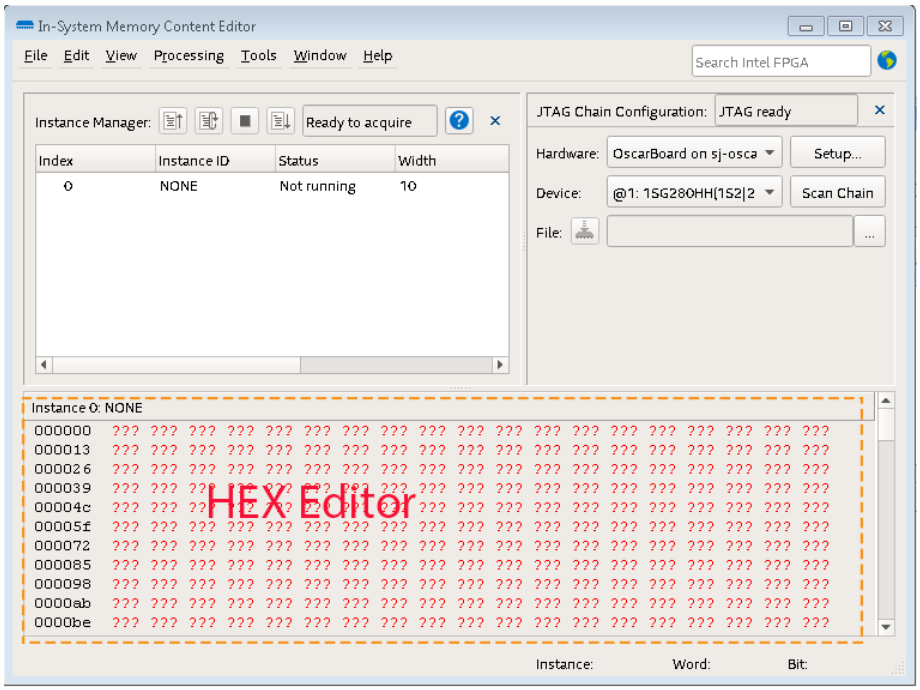
JTAG Chain Configuration Pane (In-System Memory Content Editor)
In *Intel Quartus Prime Help*

5.5. Loading Memory Instances to the ISMCE

To view the content of reconfigurable memory instances:

1. On the Intel Quartus Prime software, click **Tools ➤ In-System Memory Content Editor**.

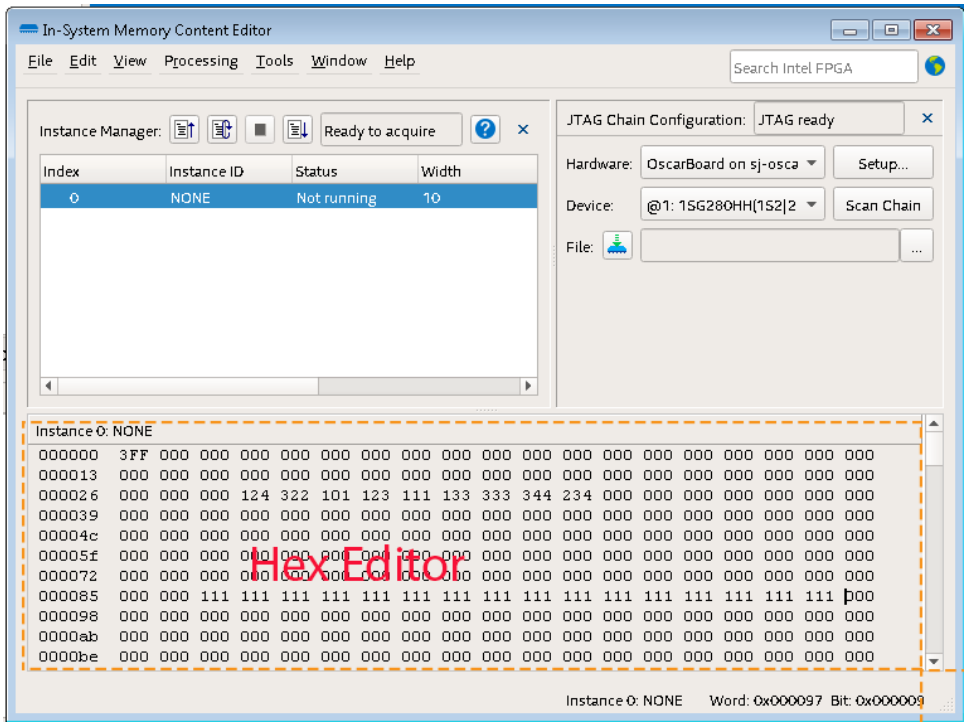
Figure 103. Hex Editor After Scanning JTAG Chain



2. In the **JTAG Chain Configuration** pane, click **Scan Chain**. The In-System Memory Content Editor sends a query to the device in the **JTAG Chain Configuration** pane and retrieves all instances of run-time configurable memories and constants.
   The **Instance Manager** pane lists all the instances of constants and memories that are runtime-modifiable. The **Hex Editor** pane displays the contents of each memory or constant instance. The memory contents in the **Hex Editor** pane appear as red question marks until you read the device.
3. Click an instance from the **Instance manager**, and then click to load the contents of that instance.

The Hex Editor now displays the contents of the instance.

Figure 104. Hex Editor Displaying Instance



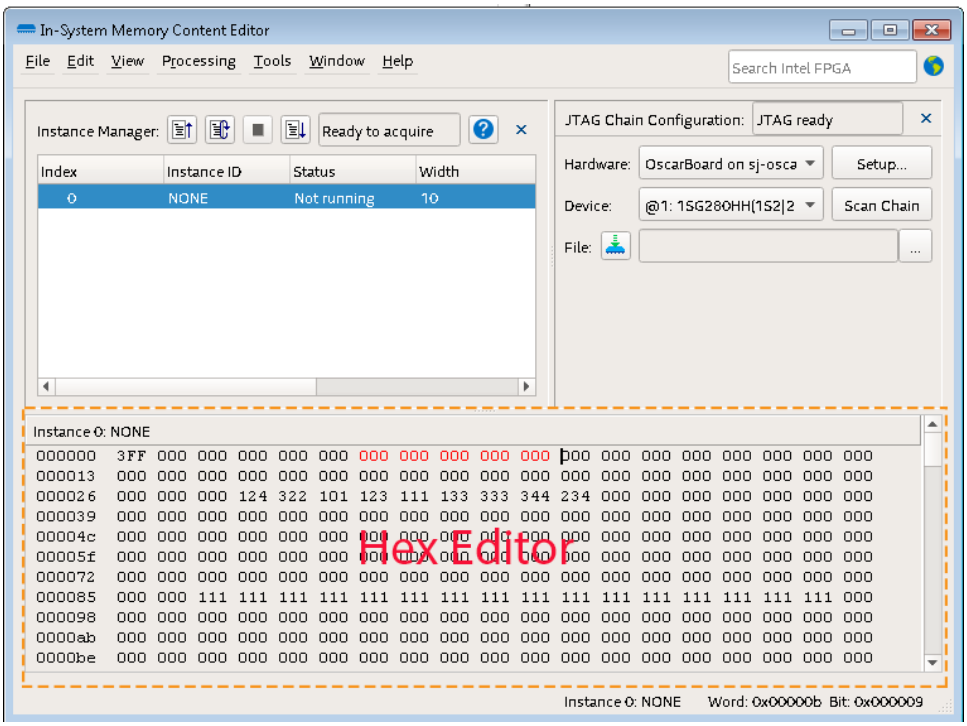
5.6. Monitoring Locations in Memory

The ISMCE allows you to monitor information in memory regions. For example, you can determine if a counter increments, or if a given word changes. For memories connected to a Nios II processor, you can observe how the software uses key regions of memory.

- Click to synchronize the Hex Editor to the current instance's content. The Hex Editor displays in red content that changed with respect to the last device synchronization.
- If you want a live output of the memory contents instead of manually synchronizing, click . Continuous read is analogous to using the Signal Tap logic analyzer in continuous acquisition, with the memory values appearing as words in the Hex Editor instead of toggling waveforms.

Note: For Intel Stratix 10 and Intel Agilex 7 devices only, ISMCE logic can perform read and write operations only when the design logic is idle. If the design logic attempts a write or an address change operation, the design logic prevails, and the ISMCE operation times out. An error message lets you know that the memory connected to the In-System Memory Content Editor instance is in use, and memory content is not updated.

Figure 105. Hex Editor After Manually Editing Content



Related Information

  In *Intel Quartus Prime Help*
- Stop In-System Memory Analysis Command (Processing Menu)
  In *Intel Quartus Prime Help*

5.7. Editing Memory Contents with the Hex Editor Pane

You can edit the contents of instances by typing values directly into the **Hex Editor** pane.

Black content on the **Hex Editor** pane means that the value read is the same as last synchronization.

1. Type content on the pane.
   The **Hex Editor** displays in blue changed content that has not been synchronized to the device.
2. Click to synchronize the content to the device.

Note: For Intel Stratix 10 and Intel Agilex 7 devices only, ISMCE logic can perform read and write operations only when the design logic is idle. If the design logic attempts a write or an address change operation, the design logic prevails, and the ISMCE operation times out. An error message lets you know that the memory connected to the In-System Memory Content Editor instance is in use, and reports the number of successful writes before the design logic requested access to the memory.

  In *Intel Quartus Prime Help*

5.8. Importing and Exporting Memory Files

The In-System Memory Content Editor allows you to import and export data values for memories that are runtime modifiable. Importing from a data file enables you to quickly load an entire memory image. Exporting to a data file allows you to save the contents of the memory for future use.

You can import or export files in `hex` or `mif` formats.

1. To import a file, click **Edit ➤ Import Data from File...**, and then select the file to import.

   If the file is not compatible, unexpected data appears in the Hex Editor.
2. To export memory contents to a file, click **Edit ➤ Export Data to File...**, and then specify the name.

5.9. Access Two or More Devices

If you have more than one device with in-system configurable memories or constants in a JTAG chain, you can launch multiple In-System Memory Content Editors within the Intel Quartus Prime software to access the memories and constants in each of the devices. Each window of the In-System Memory Content Editor can access the memories and constants of a single device.

5.10. Scripting Support

The Intel Quartus Prime software allows you to perform runtime modification of memories and constants in scripted flows.

You can enable memory and constant instances to be runtime modifiable from the HDL code. Additionally, the In-System Memory Content Editor supports reading and writing of memory contents via Tcl commands from the `insystem_memory_edit` package.

5.10.1.1. Getting Information about the insystem_memory_edit Package

You can also get information on the `insystem_memory_edit` package directly from the command line:

- For general information about the package, type:

```
quartus_stp --tcl_eval help -pkg insystem_memory_edit
```

- For information about a command in the package, type:

```
quartus_stp --tcl_eval help -cmd <command_name>
```

5.11. In-System Modification of Memory and Constants Revision History

The following revision history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.04.03	23.1	• Updated product family name to "Intel Agilex 7."
2022.12.12	22.4	• Added support for the Intel Agilex 7 device family.
2018.05.07	18.0.0	• Added support for the Intel Stratix 10 device family. • Removed obsolete example.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2015.11.02	15.1.0	Changed instances of *Quartus II* to *Intel Quartus Prime*.
June 2014	14.0.0	• Dita conversion. • Removed references to megafunction and replaced with IP core.
June 2012	12.0.0	Removed survey link.
November 2011	10.0.3	Template update.
December 2010	10.0.2	Changed to new document template. No change to content.
August 2010	10.0.1	Corrected links
July 2010	10.0.0	• Inserted links to Intel Quartus Prime Help • Removed Reference Documents section
November 2009	9.1.0	• Delete references to APEX devices • Style changes
March 2009	9.0.0	No change to content
November 2008	8.1.0	Changed to 8-1/2 x 11 page size. No change to content.
May 2008	8.0.0	• Added reference to Section V. In-System Debugging in volume 3 of the Intel Quartus Prime Handbook on page 16-1 • Removed references to the Mercury device, as it is now considered to be a “Mature” device • Added links to referenced documents throughout document • Minor editorial updates

6. Design Debugging Using In-System Sources and Probes

The Signal Tap Logic Analyzer and Signal Probe allow you to read or "tap" internal logic signals during run time as a way to debug your logic design.

Traditional debugging techniques often involve using an external pattern generator to exercise the logic and a logic analyzer to study the output waveforms during run time.

You can make the debugging cycle more efficient when you can drive any internal signal manually within your design, which allows you to perform the following actions:

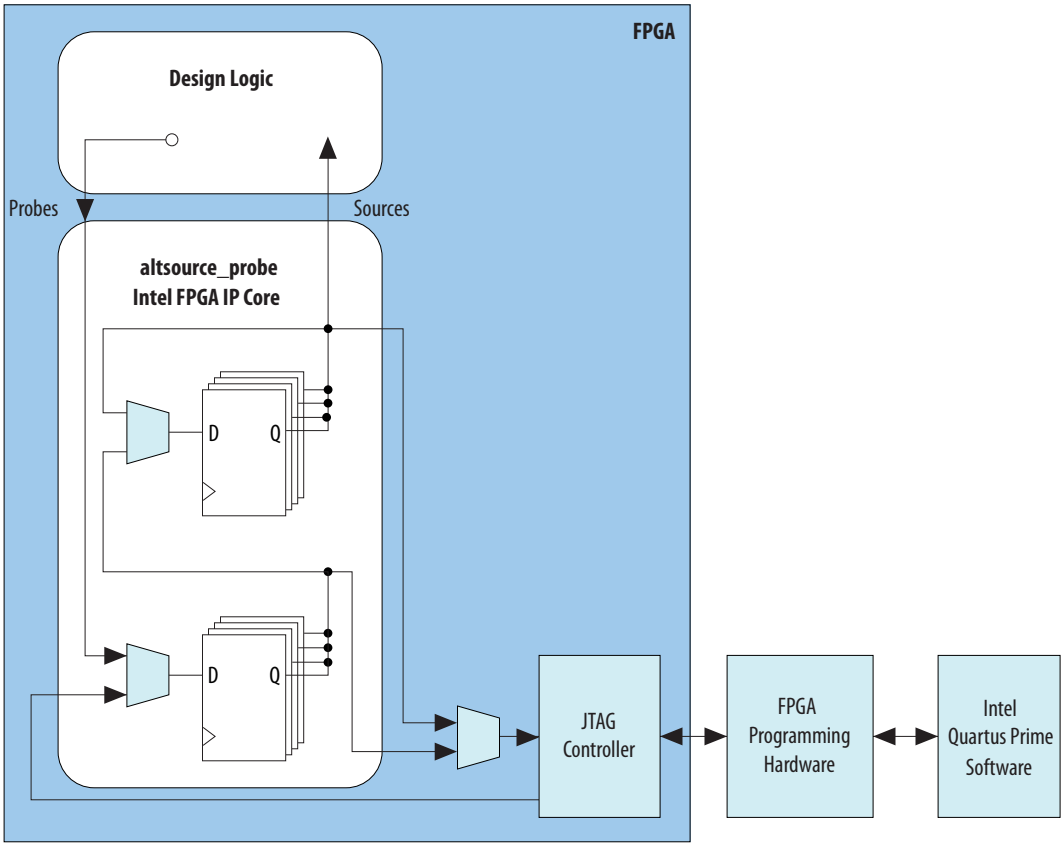
- Force the occurrence of trigger conditions set up in the Signal Tap Logic Analyzer
- Create simple test vectors to exercise your design without using external test equipment
- Dynamically control run time control signals with the JTAG chain

The In-System Sources and Probes Editor in the Intel Quartus Prime software extends the portfolio of verification tools, and allows you to easily control any internal signal and provides you with a completely dynamic debugging environment. Coupled with either the Signal Tap Logic Analyzer or Signal Probe, the In-System Sources and Probes Editor gives you a powerful debugging environment in which to generate stimuli and solicit responses from your logic design.

The Virtual JTAG IP core and the In-System Memory Content Editor also give you the capability to drive virtual inputs into your design. The Intel Quartus Prime software offers a variety of on-chip debugging tools.

The In-System Sources and Probes Editor consists of the ALTSOURCE_PROBE IP core and an interface to control the ALTSOURCE_PROBE IP core instances during run time. Each ALTSOURCE_PROBE IP core instance provides you with source output ports and probe input ports, where source ports drive selected signals and probe ports sample selected signals. When you compile your design, the ALTSOURCE_PROBE IP core sets up a register chain to either drive or sample the selected nodes in your logic design. During run time, the In-System Sources and Probes Editor uses a JTAG connection to shift data to and from the ALTSOURCE_PROBE IP core instances. The figure shows a block diagram of the components that make up the In-System Sources and Probes Editor.

Figure 107. In-System Sources and Probes Editor Block Diagram



The ALTSOURCE_PROBE IP core hides the detailed transactions between the JTAG controller and the registers instrumented in your design to give you a basic building block for stimulating and probing your design. Additionally, the In-System Sources and Probes Editor provides single-cycle samples and single-cycle writes to selected logic nodes. You can use this feature to input simple virtual stimuli and to capture the current value on instrumented nodes. Because the In-System Sources and Probes Editor gives you access to logic nodes in your design, you can toggle the inputs of low-level components during the debugging process. If used in conjunction with the Signal Tap Logic Analyzer, you can force trigger conditions to help isolate your problem and shorten your debugging process.

The In-System Sources and Probes Editor allows you to easily implement control signals in your design as virtual stimuli. This feature can be especially helpful for prototyping your design, such as in the following operations:

- Creating virtual push buttons
- Creating a virtual front panel to interface with your design
- Emulating external sensor data
- Monitoring and changing run time constants on the fly

The In-System Sources and Probes Editor supports Tcl commands that interface with all your ALTSOURCE_PROBE IP core instances to increase the level of automation.

Related Information

System Debugging Tools
For an overview and comparison of all the tools available in the Intel Quartus Prime software on-chip debugging tool suite

6.1. Hardware and Software Requirements

The following components are required to use the In-System Sources and Probes Editor:

- Intel Quartus Prime software

or

- Intel Quartus Prime Lite Edition
- Download Cable (USB-Blaster™ download cable or ByteBlaster™ cable)
- Intel FPGA development kit or user design board with a JTAG connection to device under test

The In-System Sources and Probes Editor supports the following device families:

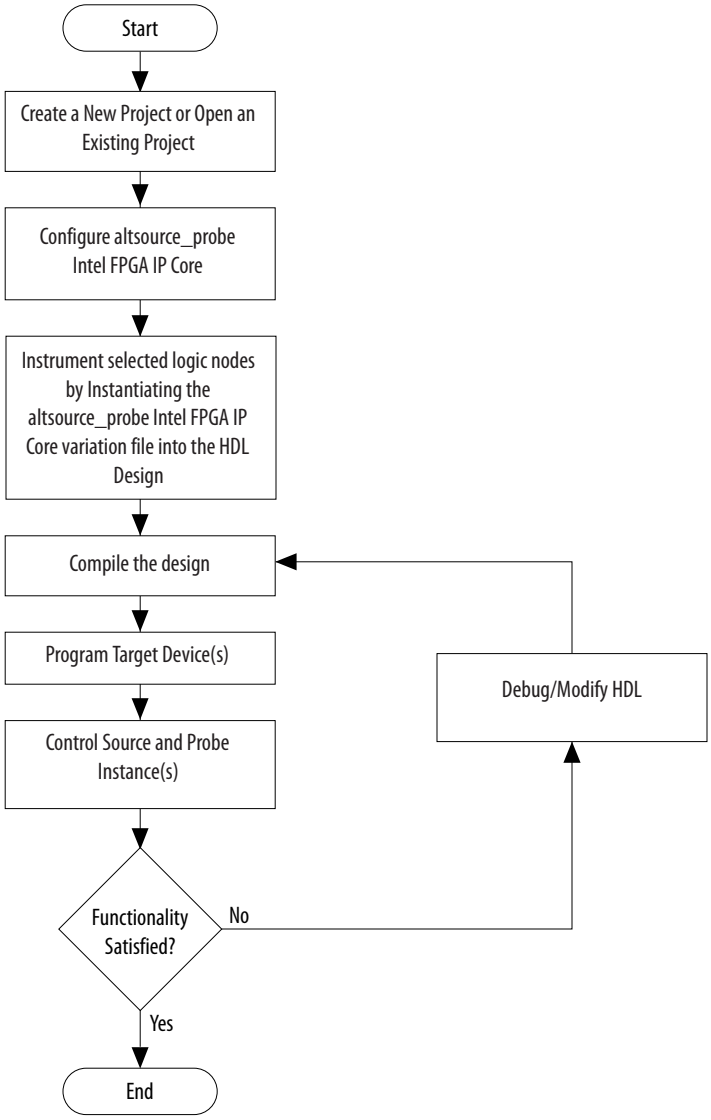
- Arria series
- Stratix series
- Cyclone series
- MAX® series

6.2. Design Flow Using the In-System Sources and Probes Editor

The In-System Sources and Probes Editor supports an RTL flow. Signals that you want to view in the In-System Sources and Probes editor are connected to an instance of the In-System Sources and Probes IP core.

After you compile the design, you can control each instance via the **In-System Sources and Probes Editor** pane or via a Tcl interface.

Figure 108. FPGA Design Flow Using the In-System Sources and Probes Editor



6.2.1. Instantiating the In-System Sources and Probes IP Core

To instantiate the In-System Sources and Probes IP core in a design:

1. In the IP Catalog (**Tools ➤ IP Catalog**), type `In-System Sources and Probes`.
2. Double-click **In-System Sources and Probes** to open the parameter editor.
3. Specify a name for the IP variation.
4. Specify the parameters for the IP variation.

The IP core supports up to 512 bits for each source, and design can include up to 128 instances of this IP core.

5. Click **Generate** or **Finish** to generate IP core synthesis and simulation files matching your specifications.
6. Using the generated template, instantiate the In-System Sources and Probes IP core in your design.

Note: The In-System Sources and Probes Editor does not support simulation. Remove the In-System Sources and Probes IP core before you create a simulation netlist.

6.2.2. In-System Sources and Probes IP Core Parameters

Use the template to instantiate the variation file in your design.

Table 34. In-System Sources and Probes IP Port Information

Port Name	Required?	Direction	Comments
`probe[]`	No	Input	The outputs from your design.
`source_clk`	No	Input	Source Data is written synchronously to this clock. This input is required if you turn on **Source Clock** in the **Advanced Options** box in the parameter editor.
`source_ena`	No	Input	Clock enable signal for `source_clk`. This input is required if specified in the **Advanced Options** box in the parameter editor.
`source[]`	No	Output	Used to drive inputs to user design.

You can include up to 128 instances of the in-system sources and probes IP core in your design, if your device has available resources. Each instance of the IP core uses a pair of registers per signal for the width of the widest port in the IP core. Additionally, there is some fixed overhead logic to accommodate communication between the IP core instances and the JTAG controller. You can also specify an additional pair of registers per source port for synchronization.

6.3. Compiling the Design

When you compile your design that includes the In-System Sources and Probes IP core, the In-System Sources and Probes and SLD Hub Controller IP core are added to your compilation hierarchy automatically. These IP cores provide communication between the JTAG controller and your instrumented logic.

You can modify the number of connections to your design by editing the In-System Sources and Probes IP core. To open the design instance you want to modify in the parameter editor, double-click the instance in the Project Navigator. You can then modify the connections in the HDL source file. You must recompile your design after you make changes.

6.4. Running the In-System Sources and Probes Editor

The In-System Sources and Probes Editor gives you control over all ALTSOURCE_PROBE IP core instances within your design. The editor allows you to view all available run time controllable instances of the ALTSOURCE_PROBE IP core in your design, provides a push-button interface to drive all your source nodes, and provides a logging feature to store your probe and source data.

To run the In-System Sources and Probes Editor:

- On the **Tools** menu, click **In-System Sources and Probes Editor.**

6.4.1. In-System Sources and Probes Editor GUI

The In-System Sources and Probes Editor contains three panes:

- **JTAG Chain Configuration**—Allows you to specify programming hardware, device, and file settings that the In-System Sources and Probes Editor uses to program and acquire data from a device.
- **Instance Manager**—Displays information about the instances generated when you compile a design, and allows you to control data that the In-System Sources and Probes Editor acquires.
- **In-System Sources and Probes Editor**—Logs all data read from the selected instance and allows you to modify source data that is written to your device.

When you use the In-System Sources and Probes Editor, you do not need to open an Intel Quartus Prime software project. The In-System Sources and Probes Editor retrieves all instances of the ALTSOURCE_PROBE IP core by scanning the JTAG chain and sending a query to the device selected in the **JTAG Chain Configuration** pane. You can also use a previously saved configuration to run the In-System Sources and Probes Editor.

Each **In-System Sources and Probes Editor** pane can access the ALTSOURCE_PROBE IP core instances in a single device. If you have more than one device containing IP core instances in a JTAG chain, you can launch multiple **In-System Sources and Probes Editor** panes to access the IP core instances in each device.

6.4.2. Programming Your Device With JTAG Chain Configuration

After you compile your project, you must configure your FPGA before you use the In-System Sources and Probes Editor.

To configure a device to use with the In-System Sources and Probes Editor, perform the following steps:

1. Open the In-System Sources and Probes Editor.
2. In the **JTAG Chain Configuration** pane, point to **Hardware,** and then select the hardware communications device. You may be prompted to configure your hardware; in this case, click **Setup**.
3. From the **Device** list, select the FPGA device to which you want to download the design (the device may be automatically detected). You may need to click **Scan Chain** to detect your target device.
4. In the **JTAG Chain Configuration** pane, click to browse for the SRAM Object File (**.sof**) that includes the In-System Sources and Probes instance or instances. (The **.sof** may be automatically detected).
5. Click **Program Device** to program the target device.

6.4.3. Instance Manager

The **Instance Manager** pane provides a list of all ALTSOURCE_PROBE instances in the design, and allows you to configure data acquisition.

The **Instance Manager** pane contains the following buttons and sub-panes:

- **Read Probe Data**—Samples the probe data in the selected instance and displays the probe data in the **In-System Sources and Probes Editor** pane.
- **Continuously Read Probe Data**—Continuously samples the probe data of the selected instance and displays the probe data in the **In-System Sources and Probes Editor** pane; you can modify the sample rate via the **Probe read interval** setting.
- **Stop Continuously Reading Probe Data**—Cancels continuous sampling of the probe of the selected instance.
- **Read Source Data**—Reads the data of the sources in the selected instances.
- **Probe Read Interval**—Displays the sample interval of all the In-System Sources and Probe instances in your design; you can modify the sample interval by clicking **Manual**.
- **Event Log**—Controls the event log that appears in the **In-System Sources and Probes Editor** pane.
- **Write Source Data**—Allows you to manually or continuously write data to the system.

Beside each entry, the **Instance Manager** pane displays the instance status. The possible instance statuses are **Not running Offloading data**, **Updating data**, and **Unexpected JTAG communication error**.

6.4.4. In-System Sources and Probes Editor Pane

The **In-System Sources and Probes Editor** pane allows you to view data from all sources and probes in your design.

The data is organized according to the index number of the instance. The editor provides an easy way to manage your signals, and allows you to rename signals or group them into buses. All data collected from in-system source and probe nodes is recorded in the event log and you can view the data as a timing diagram.

6.4.4.1. Reading Probe Data

You can read data by selecting the ALTSOURCE_PROBE instance in the **Instance Manager** pane and clicking **Read Probe Data**.

This action produces a single sample of the probe data and updates the data column of the selected index in the **In-System Sources and Probes Editor** pane. You can save the data to an event log by turning on the **Save data to event log** option in the **Instance Manager** pane.

If you want to sample data from your probe instance continuously, in the **Instance Manager** pane, click the instance you want to read, and then click **Continuously read probe data**. While reading, the status of the active instance shows **Unloading**. You can read continuously from multiple instances.

You can access read data with the shortcut menus in the **Instance Manager** pane.

To adjust the probe read interval, in the **Instance Manager** pane, turn on the **Manual** option in the **Probe read interval** sub-pane, and specify the sample rate in the text field next to the **Manual** option. The maximum sample rate depends on your computer setup. The actual sample rate is shown in the **Current interval** box. You can adjust the event log window buffer size in the **Maximum Size** box.

6.4.4.2. Writing Data

To modify the source data you want to write into the ALTSOURCE_PROBE instance, click the name field of the signal you want to change. For buses of signals, you can double-click the data field and type the value you want to drive out to the ALTSOURCE_PROBE instance. The In-System Sources and Probes Editor stores the modified source data values in a temporary buffer.

Modified values that are not written out to the ALTSOURCE_PROBE instances appear in red. To update the ALTSOURCE_PROBE instance, highlight the instance in the **Instance Manager** pane and click **Write source data**. The **Write source data** function is also available via the shortcut menus in the **Instance Manager** pane.

The In-System Sources and Probes Editor provides the option to continuously update each ALTSOURCE_PROBE instance. Continuous updating allows any modifications you make to the source data buffer to also write immediately to the ALTSOURCE_PROBE instances. To continuously update the ALTSOURCE_PROBE instances, change the **Write source data** field from **Manually** to **Continuously**.

6.4.4.3. Organizing Data

The **In-System Sources and Probes Editor** pane allows you to group signals into buses, and also allows you to modify the display options of the data buffer.

To create a group of signals, select the node names you want to group, right-click and select **Group**. You can modify the display format in the Bus Display Format and the Bus Bit order shortcut menus.

The **In-System Sources and Probes Editor** pane allows you to rename any signal. To rename a signal, double-click the name of the signal and type the new name.

The event log contains a record of the most recent samples. The buffer size is adjustable up to 128k samples. The time stamp for each sample is logged and is displayed above the event log of the active instance as you move your pointer over the data samples.

You can save the changes that you make and the recorded data to a Sources and Probes File (**.spf**). To save changes, on the File menu, click **Save**. The file contains all the modifications you made to the signal groups, as well as the current data event log.

6.5. Tcl interface for the In-System Sources and Probes Editor

To support automation, the In-System Sources and Probes Editor supports the procedures described in this chapter in the form of Tcl commands. The Tcl package for the In-System Sources and Probes Editor is included by default when you run **quartus_stp**.

The Tcl interface for the In-System Sources and Probes Editor provides a powerful platform to help you debug your design. The Tcl interface is especially helpful for debugging designs that require toggling multiple sets of control inputs. You can combine multiple commands with a Tcl script to define a custom command set.

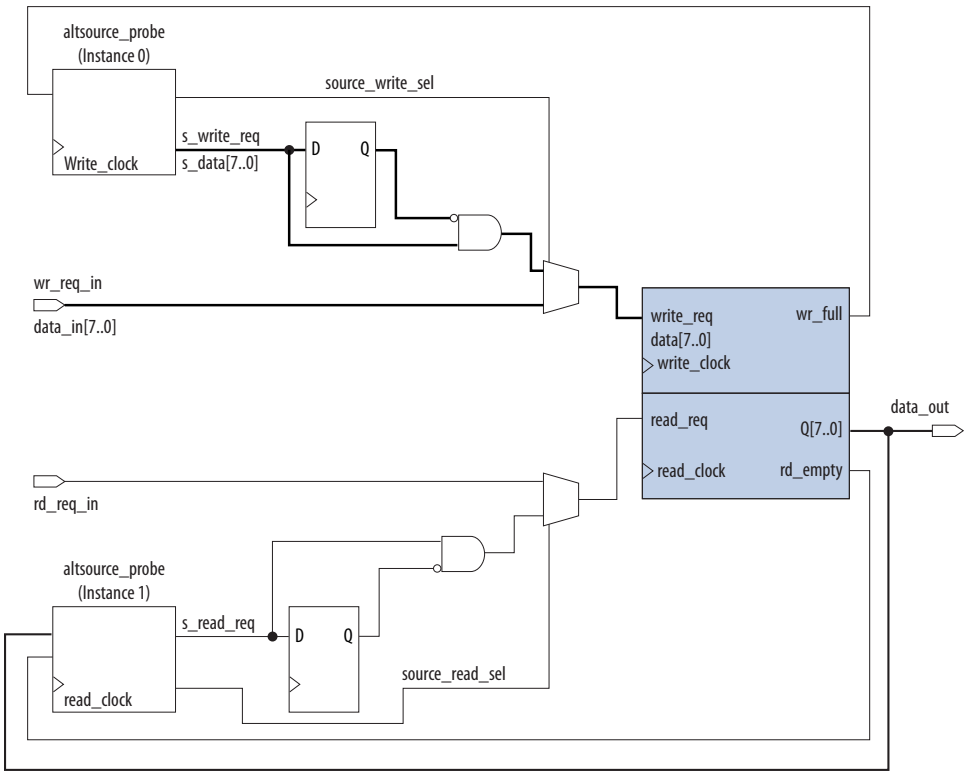
Table 35. In-System Sources and Probes Tcl Commands

Command	Argument	Description
`start_insystem_source_probe`	`-device_name<`*device name*`> -hardware_name <`*hardware name*`>`	Opens a handle to a device with the specified hardware. Call this command before starting any transactions.
`get_insystem_source_probe_instance_info`	`-device_name <`*device name*`> -hardware_name <`*hardware name*`>`	Returns a list of all ALTSOURCE_PROBE instances in your design. Each record returned is in the following format: {*<instance Index>*, *<source width>*, *<probe width>*, *<instance name>*}
`read_probe_data`	`-instance_index <`*instance_index*`> -value_in_hex` (optional)	Retrieves the current value of the probe. A string is returned that specifies the status of each probe, with the MSB as the left-most bit.
`read_source_data`	`-instance_index <`*instance_index*`> -value_in_hex` (optional)	Retrieves the current value of the sources. A string is returned that specifies the status of each source, with the MSB as the left-most bit.
`write_source_data`	`-instance_index <`*instance_index*`> -value <`*value*`> -value_in_hex` (optional)	Sets the value of the sources. A binary string is sent to the source ports, with the MSB as the left-most bit.
`end_insystem_source_probe`	None	Releases the JTAG chain. Issue this command when all transactions are finished.

The example shows an excerpt from a Tcl script with procedures that control the ALTSOURCE_PROBE instances of the design as shown in the figure below. The example design contains a DCFIFO with ALTSOURCE_PROBE instances to read from and write to the DCFIFO. A set of control muxes are added to the design to control the flow of data to the DCFIFO between the input pins and the ALTSOURCE_PROBE instances. A pulse generator is added to the read request and write request control lines to guarantee a single sample read or write. The ALTSOURCE_PROBE instances, when used with the script in the example below, provide visibility into the contents of the FIFO by performing single sample write and read operations and reporting the state of the full and empty status flags.

Use the Tcl script in debugging situations to either empty or preload the FIFO in your design. For example, you can use this feature to preload the FIFO to match a trigger condition you have set up within the Signal Tap logic analyzer.

Figure 109. DCFIFO Example Design Controlled by Tcl Script



```
## Setup USB hardware  - assumes only USB Blaster is installed and
## an FPGA is the only device in the JTAG chain
set usb [lindex [get_hardware_names] 0]
set device_name [lindex [get_device_names -hardware_name $usb] 0]
## write procedure :  argument value is integer
proc write {value} {
global device_name usb
variable full
start_insystem_source_probe -device_name $device_name -hardware_name $usb
#read full flag

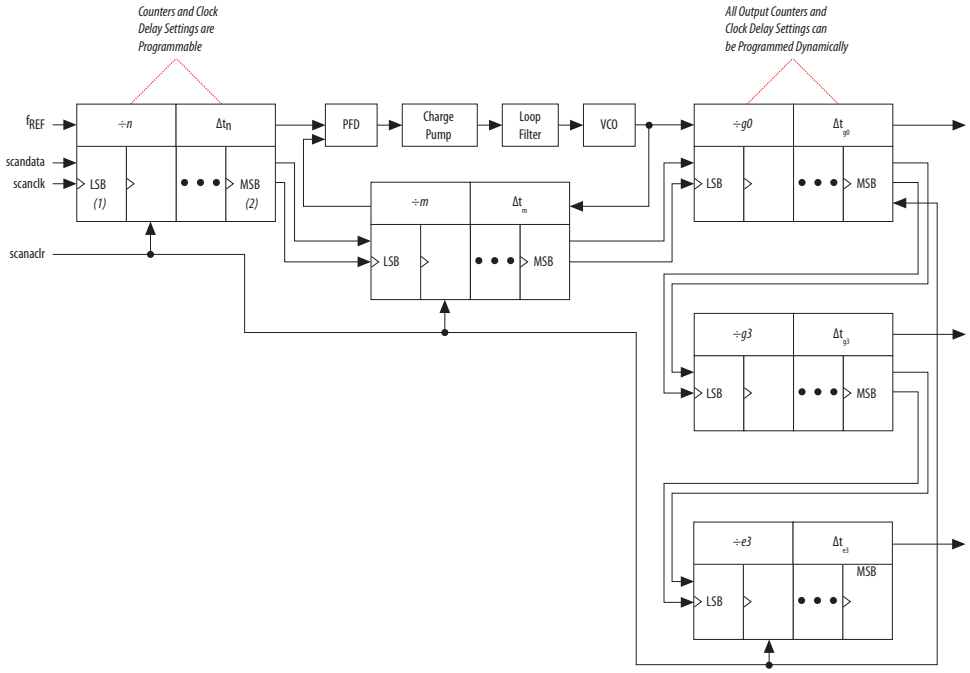
6.6. Design Example: Dynamic PLL Reconfiguration

The In-System Sources and Probes Editor can help you create a virtual front panel during the prototyping phase of your design. You can create relatively simple, high functioning designs of in a short amount of time. The following PLL reconfiguration example demonstrates how to use the In-System Sources and Probes Editor to provide a GUI to dynamically reconfigure a Stratix PLL.

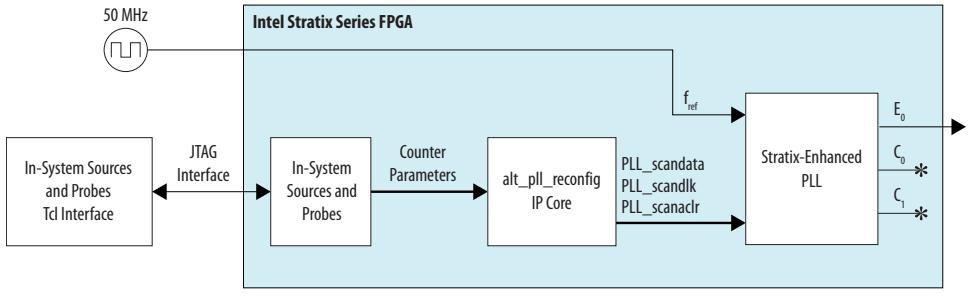
Stratix PLLs allow you to dynamically update PLL coefficients during run time. Each enhanced PLL within the Stratix device contains a register chain that allows you to modify the pre-scale counters (m and n values), output divide counters, and delay counters. In addition, the ALTPLL_RECONFIG IP core provides an easy interface to access the register chain counters. The ALTPLL_RECONFIG IP core provides a cache that contains all modifiable PLL parameters. After you update all the PLL parameters in the cache, the ALTPLL_RECONFIG IP core drives the PLL register chain to update the PLL with the updated parameters. The figure shows a Stratix-enhanced PLL with reconfigurable coefficients.

Figure 110. Stratix-Enhanced PLL with Reconfigurable Coefficients



The following design example uses an ALTSOURCE_PROBE instance to update the PLL parameters in the ALTPLL_RECONFIG IP core cache. The ALTPLL_RECONFIG IP core connects to an enhanced PLL in a Stratix FPGA to drive the register chain containing the PLL reconfigurable coefficients. This design example uses a Tcl/Tk script to generate a GUI where you can enter in new m and n values for the enhanced PLL. The Tcl script extracts the m and n values from the GUI, shifts the values out to the ALTSOURCE_PROBE instances to update the values in the ALTPLL_RECONFIG IP core cache, and asserts the reconfiguration signal on the ALTPLL_RECONFIG IP core. The reconfiguration signal on the ALTPLL_RECONFIG IP core starts the register chain transaction to update all PLL reconfigurable coefficients.

Figure 111. Block Diagram of Dynamic PLL Reconfiguration Design Example



This design example was created using a Nios II Development Kit, Stratix Edition. The file `sourceprobe_DE_dynamic_pll.zip` contains all the necessary files for running this design example, including the following:

- `Readme.txt`—A text file that describes the files contained in the design example and provides instructions about running the Tk GUI shown in the figure below.
- `Interactive_Reconfig.qar`—The archived Intel Quartus Prime project for this design example.

6.7. Design Debugging Using In-System Sources and Probes Revision History

The following revision history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.07.31	22.1	• Corrected incorrect space characters in *Tcl interface for the In-System Sources and Probes Editor*.
2022.07.08	22.1	• Fixed broken link in "Design Example: Dynamic PLL Reconfiguration".
2019.06.11	18.1.0	Rebranded megafunction to Intel FPGA IP core
2018.05.07	18.0.0	Added details on finding the In-System Sources and Probes in the IP Catalog.
2016.10.31	16.1.0	Implemented Intel rebranding.
2015.11.02	15.1.0	Changed instances of *Quartus II* to *Intel Quartus Prime*.
June 2014	14.0.0	Updated formatting.
June 2012	12.0.0	Removed survey link.
November 2011	10.1.1	Template update.
December 2010	10.1.0	Minor corrections. Changed to new document template.
July 2010	10.0.0	Minor corrections.
November 2009	9.1.0	• Removed references to obsolete devices. • Style changes.

continued...

Document Version	Intel Quartus Prime Version	Changes
March 2009	9.0.0	No change to content.
November 2008	8.1.0	Changed to 8-1/2 x 11 page size. No change to content.
May 2008	8.0.0	• Documented that this feature does not support simulation on page 17–5 • Updated Figure 17–8 for Interactive PLL reconfiguration manager • Added hyperlinks to referenced documents throughout the chapter • Minor editorial updates

7. Analyzing and Debugging Designs with System Console

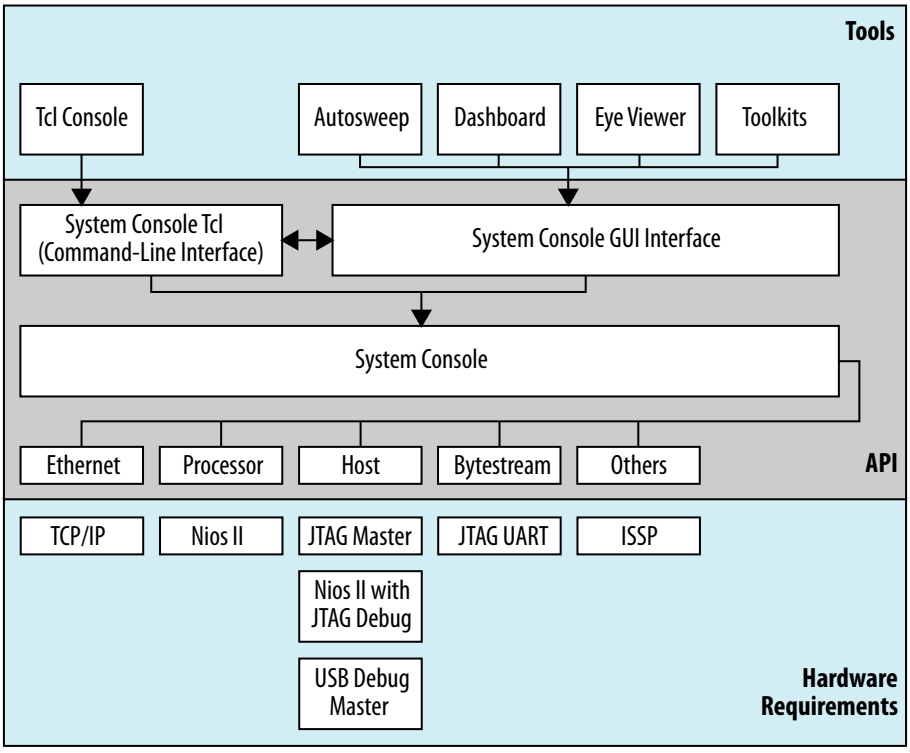
7.1. Introduction to System Console

System Console provides visibility into your design and allows you to perform system-level debug on an FPGA at run-time. System Console performs tests on debug-enabled Intel FPGA IP. A variety of debug services provide read and write access to elements in your design.

- Perform board bring-up with finalized or partially complete designs.
- Automate run-time verification through scripting across multiple devices.
- Debug transceiver links, memory interfaces, and Ethernet interfaces.
- Integrate your debug IP into the debug platform.
- Perform system verification with MATLAB and Simulink.

Figure 113. System Console Tools

The System Console API supports services that access your design in operation.



System Console also provides the hardware debugging infrastructure to support operation and customization of debugging "toolkits." Toolkits are small applications that you can use to perform system-level debug of such elements as external memory interfaces, Ethernet interfaces, PCI Express interfaces, transceiver PHY interfaces, and various other debugging functions. The Intel Quartus Prime software includes the Available System Debugging Toolkits on page 175. For advanced users, System Console also supports Tcl commands that allow you to define and operate your own custom toolkits, as *System Console and Toolkit Tcl Command Reference Manual* describes.

Related Information

- System Console Online Training
- System Console and Toolkit Tcl Command Reference Manual

7.1.1. IP Cores that Interact with System Console

System Console runs on your host computer and communicates with your running design through debug agents. Debug agents are the soft-logic embedded in some IP cores that enable debug communication with the host computer.

You can instantiate debug IP cores using the Intel Quartus Prime software IP Catalog and IP parameter editor. Some IP cores are enabled for debug by default, while you must enable debug for other IP cores through options in the parameter editor. Some debug agents have multiple purposes.

When you include debug-enabled IP cores in your design, you can access large portions of the design running on hardware for debugging purposes. Debug agents allow you to read and write to memory and alter peripheral registers from the tool.

Services associated with debug agents in the running design can open and close as needed. System Console determines the communication protocol with the debug agent. The communication protocol determines the best board connection to use for command and data transmission.

The Programmable SRAM Object File (`.sof`) that the Intel Quartus Prime Assembler generates for device programming provides the System Console with channel communication information. When you open System Console from the Intel Quartus Prime software GUI, with a project open that includes a `.sof`, System Console automatically finds and links to the device(s) it detects. When you open System Console without an open project, or with an unrelated project open, you can manually load the `.sof` file that you want, and then the design linking occurs automatically if the device(s) match.

Related Information

- Available System Debugging Toolkits on page 175
- WP-01170 System-Level Debugging and Monitoring of FPGA Designs

7.1.2. Services Provided through Debug Agents

By adding the appropriate debug agent to your design, System Console services can use the associated capabilities of the debug agent.

Table 36. Common Services for System Console

Service	Function	Debug Agent Providing Service
host	Access a memory-mapped agent connected to the host interface.	• Nios II with debug • JTAG to Avalon Master Bridge • USB Debug Master
agent	Allows a host component to access a single agent without needing to know the location of the agent in the host's memory map. Any agent that is accessible to a System Console host can provide this service.	• Nios II with debug • JTAG to Avalon Master Bridge • USB Debug Master If an SRAM Object File (`.sof`) is loaded, then agents accessed by a debug host provide the agent service.
issp	The In-System Sources and Probes (ISSP) service provides scriptable access to the In-System Sources and Probes Intel FPGA IP for generating stimuli and soliciting responses from your logic design.	In-System Sources and Probes Intel FPGA IP
processor	• Start, stop, or step the processor. • Read and write processor registers.	Nios II with debug
JTAG UART	The JTAG UART is an Avalon memory mapped agent that you can use in conjunction with System Console to send and receive byte streams.	JTAG UART

Note: The following debug agent IP cores in the IP Catalog do not support VHDL simulation generation in the current version of the Intel Quartus Prime software:

- JTAG Debug Link
- JTAG Hub Controller System
- USB Debug Link

7.1.3. System Console Debugging Flow

The System Console debugging flow includes the following steps:

1. Add debug-enabled Intel FPGA IP to your design.
2. Compile the design.
3. Connect to a board and program the FPGA.
4. Start System Console.
5. Locate and open a System Console service.
6. Perform debug operations with the service.
7. Close the service.

7.2. Starting System Console

You can use any of the following methods to start System Console:

- To start System Console from the Intel Quartus Prime software GUI:

  Click **Tools ➤ System Debugging Tools ➤ System Console**.

  Or

  Click **Tools ➤ System Debugging Tools ➤ System Debugging Toolkits**.
- To start System Console from Platform Designer:

  Click **Tools ➤ System Console**
- To start Stand-Alone System Console:
  1. Navigate to the **Download Center** page, click **Additional Software**, and download and install Intel Quartus Prime Pro Edition Programmer and Tools.
  2. On the Windows Start menu, click **All Programs ➤ Intel FPGA <*version*> ➤ Programmer and Tools ➤ System Console**.
- To start System Console from a Nios II Command Shell:
  1. On the Windows Start menu, click **All Programs ➤ Intel ➤ Nios II EDS <*version*> ➤ Nios II<*version*> ➤ Command Shell**.
  2. Type `system-console --project_dir=<project directory>` and specify a directory that contains `.qsf` or `.sof` files.

     Note: Type `--help` for System Console help.

7.2.1. Customizing System Console Startup

You can customize your System Console startup environment, as follows:

- Add commands to the `system_console_rc` configuration file located at:
  - `<$HOME>/system_console/system_console_rc.tcl`

  The file in this location is the user configuration file, which only affects the owner of the home directory.
- Specify your own design startup configuration file with the command-line argument `--rc_script=<path_to_script>`, when you launch System Console from the Nios II command shell.
- Use the `system_console_rc.tcl` file in combination with your custom `rc_script.tcl` file. In this case, the `system_console_rc.tcl` file performs System Console actions, and the `rc_script.tcl` file performs your debugging actions.

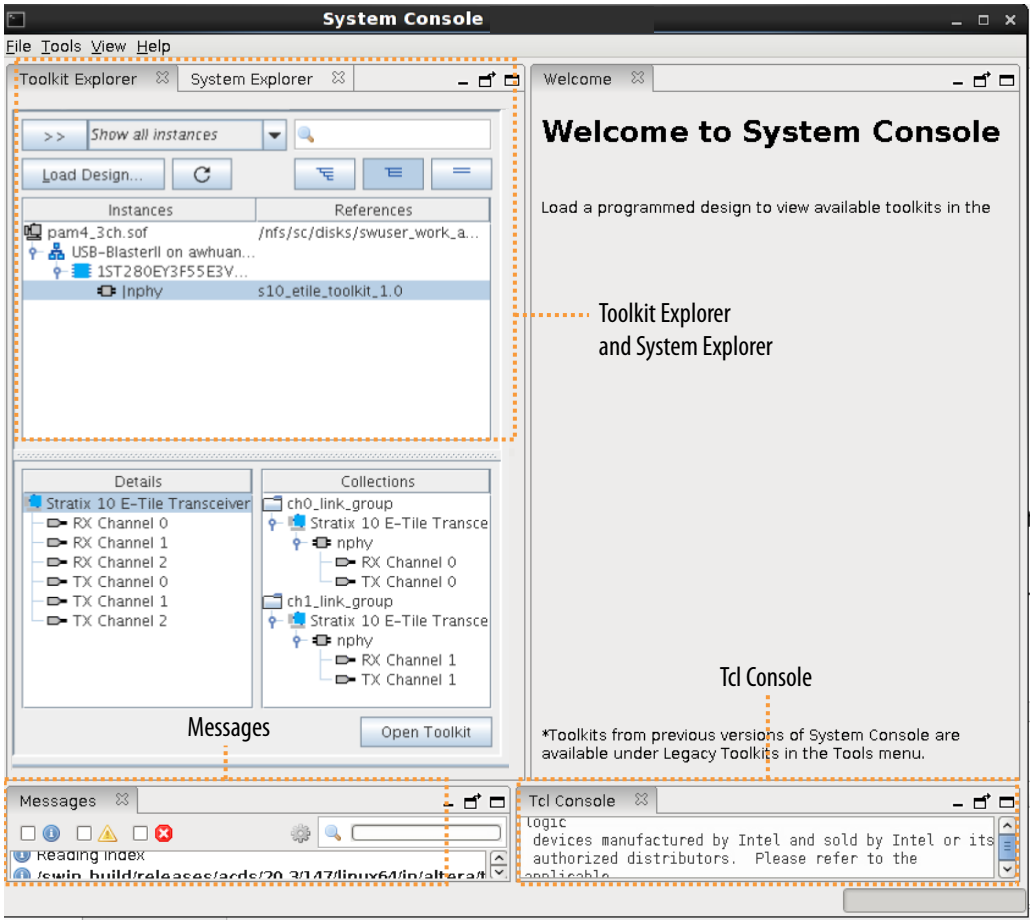
On startup, System Console automatically runs the Tcl commands in these files. The commands in the `system_console_rc.tcl` file run first, followed by the commands in the `rc_script.tcl` file.

7.3. System Console GUI

The System Console GUI consists of a main window with the following panes that allow you to interact with the design currently running on the FPGA device:

- **Toolkit Explorer**—displays all available toolkits and launches tools that use the System Console framework.
- **System Explorer**—displays a list of interactive instances in your design, including board connections, devices, designs, servers, and scripts.
- **Main View**—initially displays the welcome screen. All toolkits that you launch display in this view.
- **Tcl Console**—allows you to interact with your design through individual Tcl commands or by sourcing Tcl scripts, writing procedures, and using System Console APIs.
- **Messages**—displays status, warning, and error messages related to connections and debug actions.

Figure 114. System Console GUI



System Console GUI also provides the **Autosweep**, **Dashboard**, and **Eye Viewer** panes, that display as tabs in the **Main View**.

System Console Views on page 164

Toolkit Explorer Pane on page 171

System Explorer Pane on page 171

Customizing, Saving, and Resetting the System Console Layout on page 173

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.3.1. System Console Views

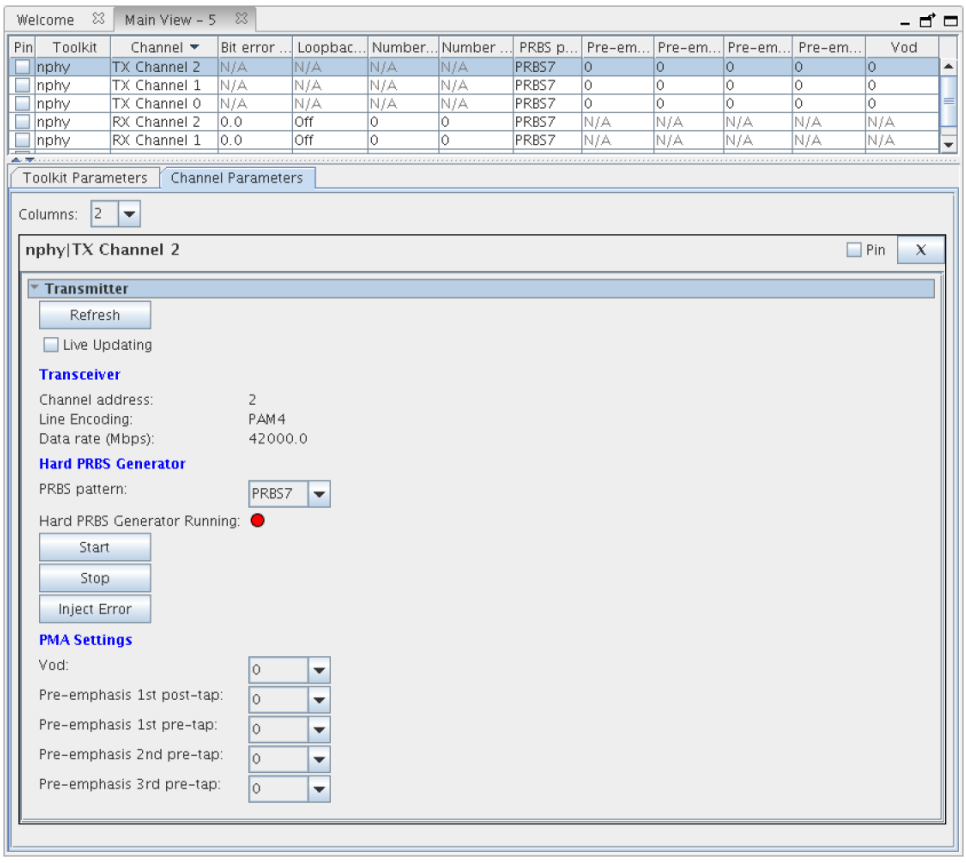
System Console provides the Main, Autosweep, Dashboard, and Eye Viewer views.

7.3.1.1. Main View

The **Main View** in System Console allows you to visualize certain parameter values of the IP that the toolkit targets. These parameter values can be static values from compile-time parameterization, or dynamic values read from the hardware (like reading from CSR registers) at run-time.

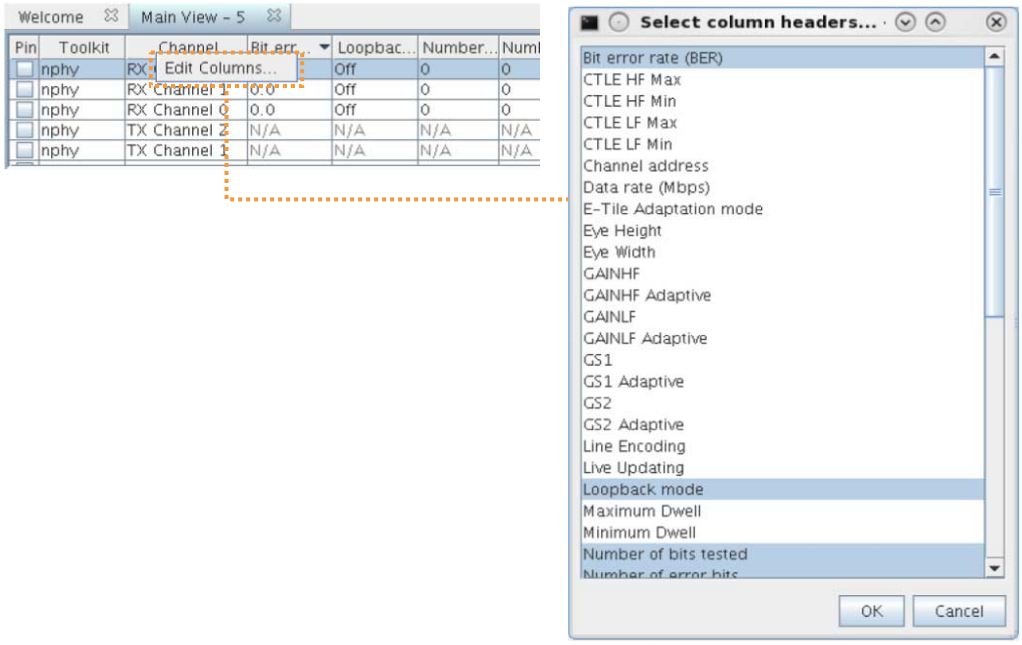
The **Main View** GUI controls allow you to control or configure the IP on the hardware.

Figure 115. Main View of the System Console



If you are using a toolkit, you can add or remove columns from the table in the **Main View**. Right-click on the table header and select **Edit Columns** in the right-click menu. The **Select column headers** dialog box is displayed where you can choose to include more columns, as shown in the following image:

Figure 116. Column Selection in the Main View Table



Parameters Pane

The **Main View** provides the **Parameters** pane that has two tabs, one for global parameters (those not associated with a given channel) and another for channel parameters (those associated with channels). The **Channel Parameters** tab is filled with per-channel parameter editors based on channel row selection in the **Status Table**, as System Console Toolkit Explorer shows.

Status Table Pane

The **Status Table** does not appear for toolkits that do not define channels. The **Status Table** allows you to view status information across all channels of a collection or a toolkit instance, as well as execute actions across multiple channels, as System Console Toolkit Explorer shows. You can execute bulk actions spanning multiple channels by selecting desired channels, and right-clicking and exploring the **Actions** sub-menu.

You can also use the **Status Table** to select which channel to display in the Parameters Pane. The channels you select in the Status Table are shown in the **Parameters Pane**. You can use the **Pin** setting for a channel to display the channel, regardless of the current selection in the **Status Table**.

If you develop your own toolkit, you can design the layout and GUI elements in the **Main View** using the Toolkit Tcl API. You can also define how each GUI element interacts with the hardware.

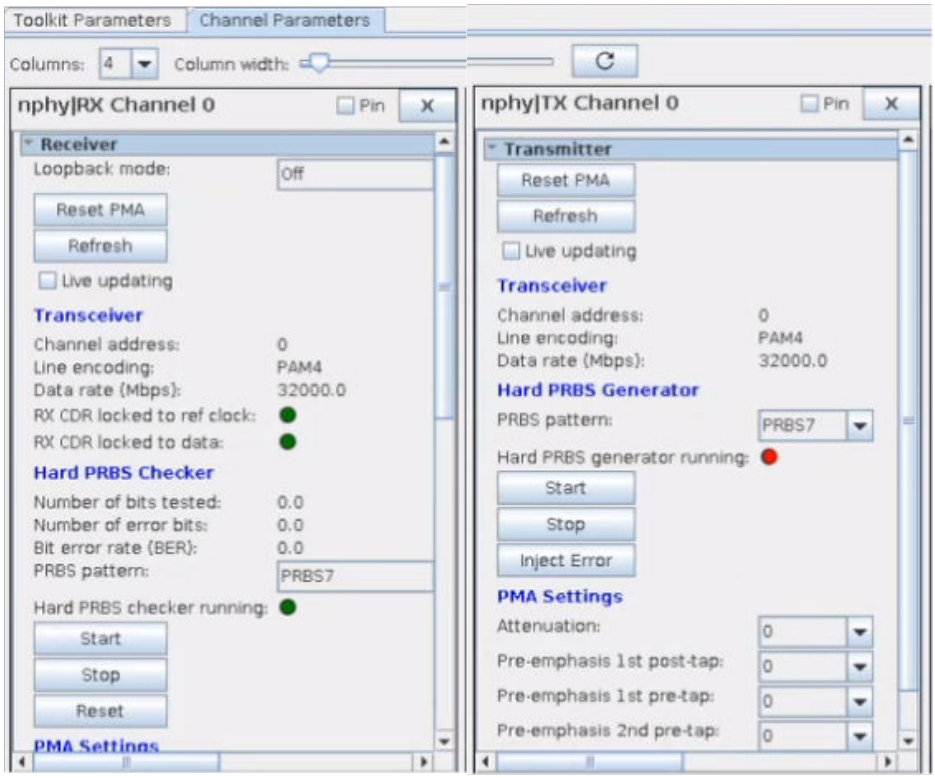
7.3.1.1.1. Link Pair View

Displaying Links With the Main View

You can use the **Main View** to simultaneously display and control associated TX and RX pairs:

1. Select both RX and TX channels in the **Status Table**.
2. Right-click to view the context-sensitive menu.
3. Navigate to the **Actions** menu.

Figure 117. Displaying Links in the Main View



Custom Groups with Links

In the **Status Table**, links are displayed like any other channel, with the exception that their parameter lists encompass all parameters from the associated TX and RX channels. If you create a group with a link and its associated TX and RX instance channels, the link row in the **Status Table** populates in all columns. Whereas, for the independent TX and RX channel rows, only parameters associated with that channel populate the **Status Table**.

Configuring a Link

You have the option to configure links in the following ways:

- Through the provided status table in the **Main View**.
- Through configuration options provided for the associated TX and RX channels.

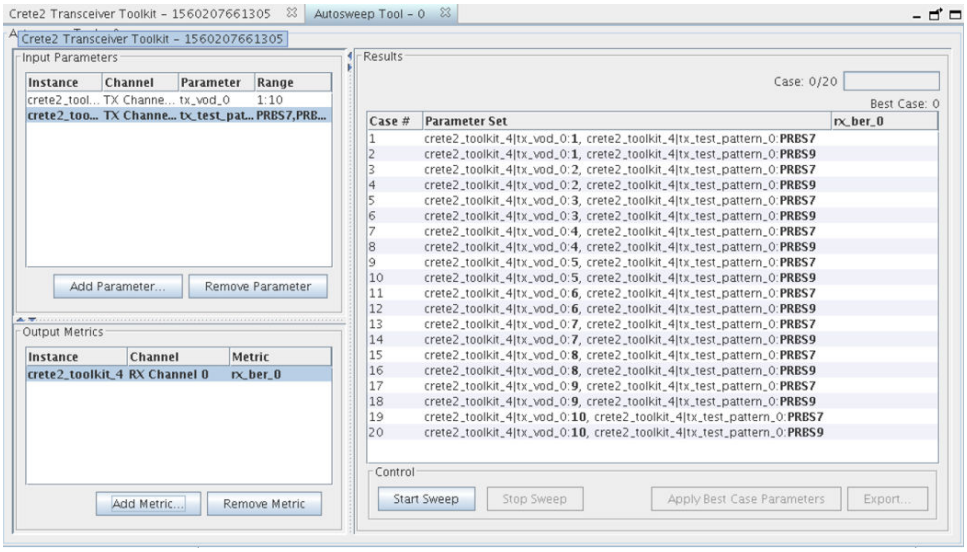
Option provided for the TX and RX channels allow you to individually manipulate each associated channel. You can manipulate multiple parameters simultaneously by selecting one or more items, and then right-clicking parameters in the status table.

7.3.1.2. Autosweep View

The **Autosweep** view allows you to sweep over IP parameters to find the best combination and define your own quality metrics for a given Autosweep run.

The System Console **Autosweep** view allows you to define your own quality metrics for a given Autosweep run.

Figure 118. Autosweep View of the System Console



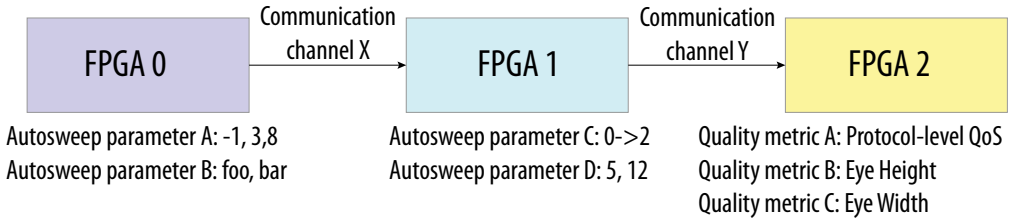
By default, the **Autosweep** view launches without any connection to a toolkit instance(s) or channel pair(s). You can add parameters by clicking **Add Parameter** and selecting parameters from specific toolkit instance(s) in the **Select Parameter** dialog box. You can remove parameters by selecting them and clicking **Remove Parameter**. Alternatively, you can add your own parameters and create as many **Autosweep** views as you want, to allow sweeping over different parameters on different channels of the same instance, or different instances entirely.

To save a parameter set for future use, select the parameter set, and then click **Export Settings**. To load a collection, click **Import Settings**.

Important: Any channel of a particular instance that has parameters currently being swept over in one **Autosweep** view cannot have other (or the same) parameters swept over in a different **Autosweep** view. For example, if one **Autosweep** view is currently sweeping over parameters from `InstA | Channel 0`, and another **Autosweep** view has parameters from `InstA | Channel 0`, an error is displayed if you attempt to start the second sweep before the first has completed. This prevents you from changing more things than are expected from a given run of autosweep.

Consider the following example complex system with parameters spread across multiple devices:

Figure 119. An Example of the Autosweep System



The **Autosweep** view allows you to sweep such a complex system when the multiple devices are visible to System Console. You can select the quality metrics from instances different from those you sweep. You can even span levels of the hardware stack from the PMA-level up to protocol-level signaling.

Results

The **Results** table is populated with one row per autosweep iteration. For every output quality metric added in the **Output Metrics** section, a column for that metric is added to the **Results** table, with new row entries added to the bottom. This format allows sorting of the results by quality metric of the system under test, across many combinations of parameters, to determine which parameter settings achieve best real-world results.

The **Results** table allows visualizing or copying the parameter settings associated with a given case, and sorting by quality metrics. Sort the rows of the table by clicking on the column headers.

Control

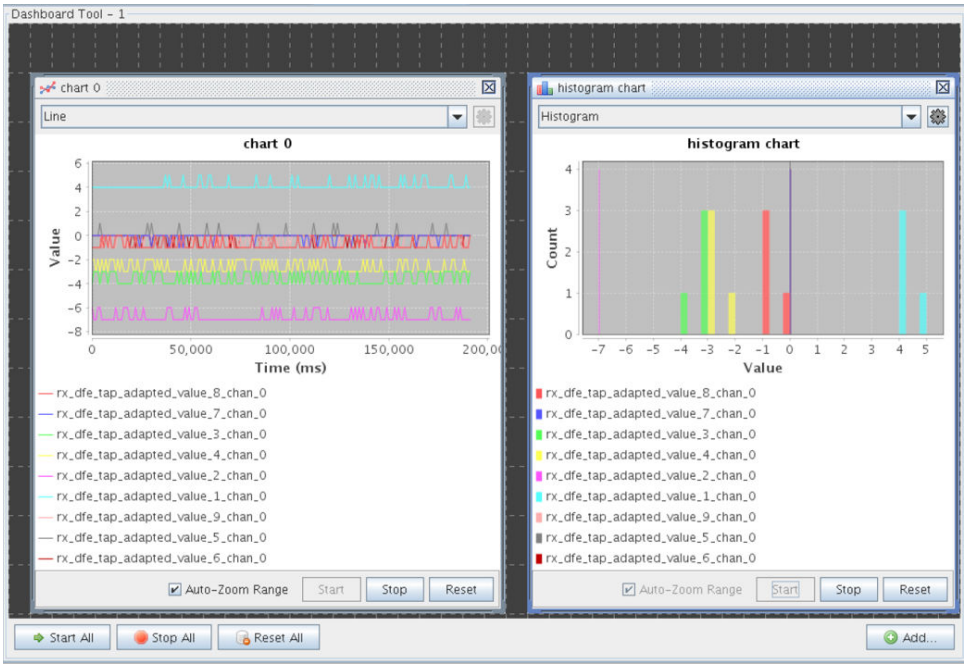
The **Control** pane of the **Autosweep** view allows starting an autosweep run, once you define at least one input parameter and one quality metric. Starting a run, allowing all combinations to complete, and then pressing the **Start** button re-runs the same test case. Pressing the **Stop** button cancels a currently running autosweep.

7.3.1.3. Dashboard View

The **Dashboard** view allows you to visualize the changes to toolkit parameters over time.

The **Dashboard** provides options to view a line chart, histogram, pie chart or bar graph, and a data history. There is no limit imposed on the number of instances of the **Dashboard** view open at once. However, a performance penalty occurs if you update a high number of parameters at a high frequency simultaneously.

Figure 120. Dashboard View of the System Console



The **Add Parameter** dialog box opens when you click the **Add** button. Only those parameters that declare the `allows_charting` parameter property are available for selection in the **Add Parameter** dialog box.

7.3.1.4. Eye Viewer

The System Console **Eye Viewer** allows you to configure, run, and render eye scans. The **Eye Viewer** allows independent control of the eye for each transceiver instance. System Console allows you to open only one **Eye Viewer** per-instance channel pair at any given time. Therefore, there is a one-to-one mapping of a given **Eye Viewer** GUI to a given instance of the eye capture hardware on the FPGA. Click **Tools ➤ Eye Viewer** to launch the **Eye Viewer**.

Eye Viewer Controls

The **Eye Viewer** controls allow you to configure toolkit-specific settings for the current **Eye Viewer** scan. The parameters in the **Eye Viewer** affect the behavior and details of the eye scan run.

Start / Stop Controls

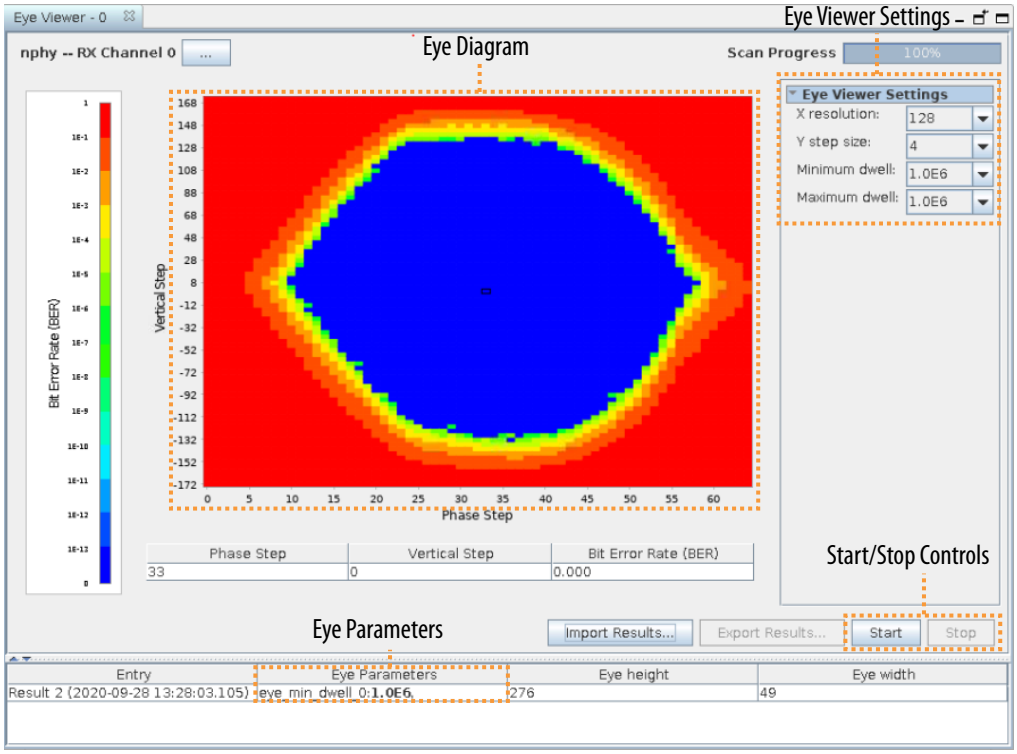
The **Eye Viewer** provides **Start** and **Stop** controls. The **Start** button starts the eye scanning process while the **Stop** button cancels an incomplete scan.

Note: The actual scanning controls, configurations, and metrics shown with the **Eye Viewer** vary by toolkit.

Eye Diagram Visualization

The eye diagram displays the transceiver eye captured from on-die instrumentation (ODI) with a color gradient.

Figure 121. Eye Viewer (E-Tile Transceiver Native PHY Toolkit Example)



Results Table

The **Results** table displays results and statistics of all eye scans. While an eye scan is running, you cannot view any partial results. However, there is a progress bar showing the current progress of the eye scan underway.

When an eye scan successfully completes, a new entry appears in the **Results** table, and that entry automatically gains focus. When you select a given entry in the **Results** table, the eye diagram renders the associated eye data. You can right-click in the **Results** table to do the following:

- Apply the test case parameters to the device
- Delete an entry

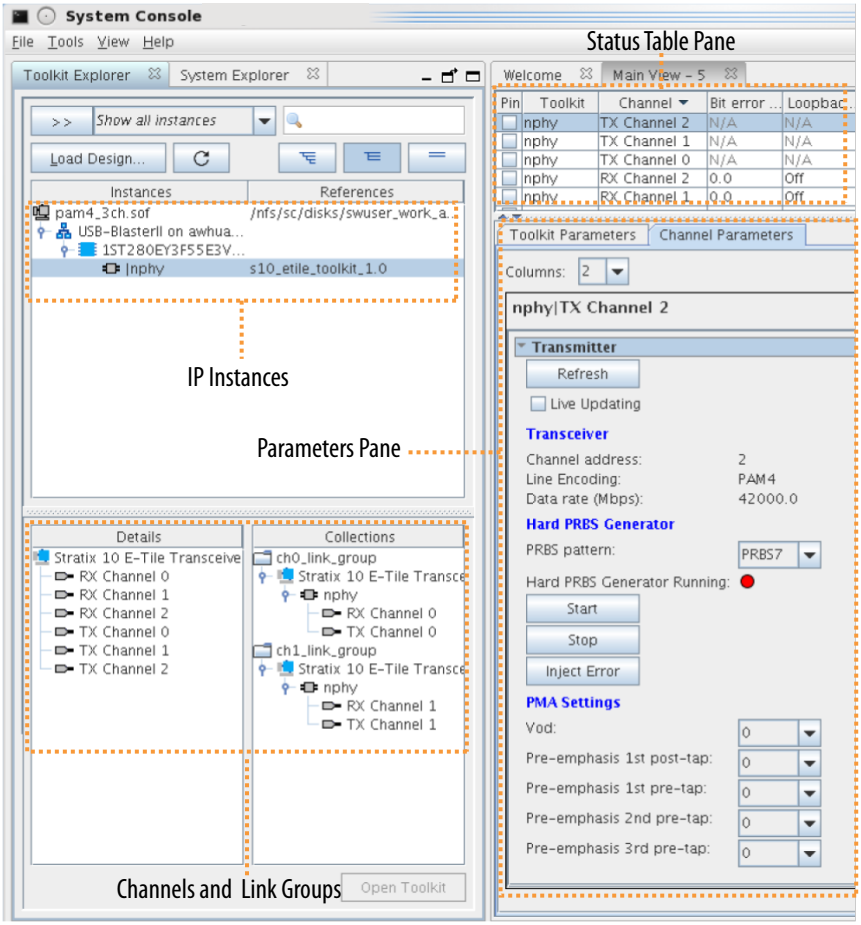
If developing your own toolkit that includes the **Eye Viewer**, the BER gradient is configurable, and the eye diagram GUI supports the following features:

- A BER tool-tip for each cell
- Ability to export the map as PNG
- Zoom

7.3.2. Toolkit Explorer Pane

The **Toolkit Explorer** pane displays all available toolkits and launches tools that use the System Console framework. When you load a design that contains debug-enabled IP, the **Toolkit Explorer** displays the design instances, along with a list of channels and channel collections for debugging. To interact with a channel or a toolkit, double-click on it to launch the **Main View** tabbed window, as shown in the following image:

Figure 122. System Console Toolkit Explorer



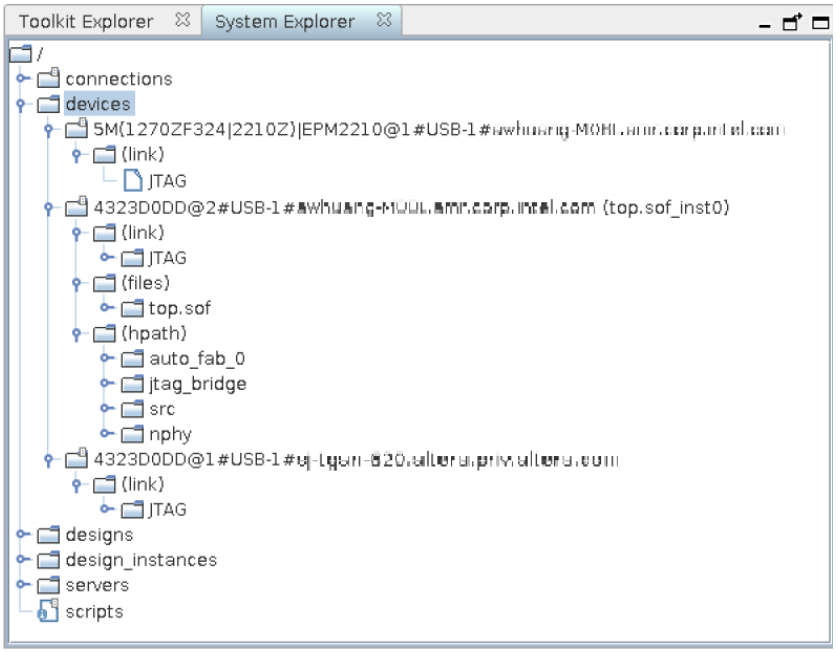
Note: If you close **Toolkit Explorer**, you can reopen it by clicking **View ➤ Toolkit Explorer**.

7.3.3. System Explorer Pane

The **System Explorer** pane displays a list of interactive instances from the design loaded on a connected device. This includes the following items:

- IP instances with debug toolkit capabilities
- IP instances with a debug endpoint

Figure 123. System Explorer Pane



Additionally, the **System Explorer** also displays custom toolkit groups and links that you create. **System Explorer** organizes the interactive instances according to the available device connections. The **System Explorer** contains a **Links** instance, and may contain a **Files** instance. The **Links** instance shows debug agents (and other hardware) that System Console can access. The **Files** instance contains information about the programming files loaded from the Intel Quartus Prime project for the device.

The **System Explorer** provides the following information:

- **Devices**—displays information about all devices connected to the System Console.
- **Scripts**—stores scripts for easy execution.
- **Connections**—displays information about the board connections visible to System Console, such as the Intel FPGA Download Cable. Multiple connections are possible.
- **Designs**—displays information about Intel Quartus Prime designs connected to System Console. Each design represents a loaded `.sof` file.
- Right-click on some of the instances to execute related commands.
- Instances that include a message display a message icon. Click on the instance to view the messages in the **Messages** pane.

7.3.4. Customizing, Saving, and Resetting the System Console Layout

The System Console GUI includes the default **System Console** layout (for general system-level debug) and **Toolkit Explorer** layout (for debugging with toolkits) layouts. These layouts are tailored for system level debug and running debug toolkits, respectively.

You can customize these layouts for your preferences in the System Console workspace, save and reload your custom layout, and reset the layout to default. When you re-load a design, System Console restores the last saved workspace associated with that design.

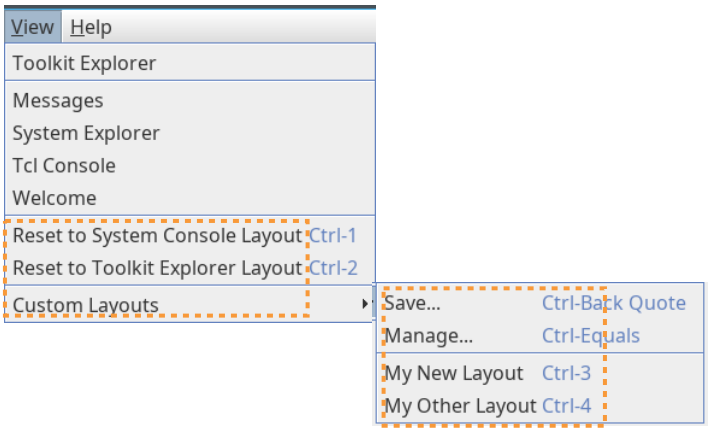
To customize the layout to suit your task flow and preferences:

Follow these steps to customize and save the Platform Designer layout:

1. Click tabbed items on the **View** or **Tools** menus to display and then optionally arrange, remove, or group the items to suit your preferences:
   - Drag, drop, and group the items in the workspace to match your task flow and preferences.
   - Close or dock items that you are not using.
   - Dock items in the main frame as a group, or individually by clicking the tab control in the upper-right corner of the main frame.
   - Tool tips on the upper-right corner of the tabbed item suggest potential workspace arrangements, for example, restoring or disconnecting a tab from the workspace.

     Note: You cannot include the **Autosweep**, **Dashboard**, **Eye Viewer**, or **Legacy Toolkits** tabs from **Tools** menu in custom layouts. You must first close any of these items before saving a layout.
2. To save the current workspace configuration as a custom layout, click **View ➤ Custom Layouts ➤ Save** and specify a layout **Name**. System Console saves the custom layouts and order in the `layouts.ini` file in project directory, and adds the layout to the **Custom Layouts** list.

Figure 124. View Menu Layouts

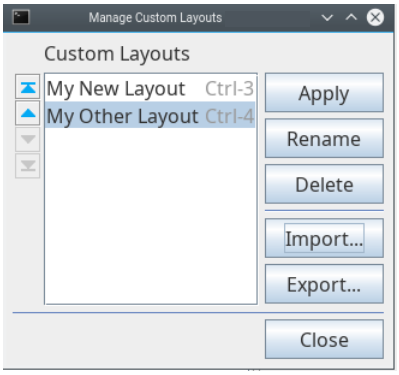


3. Use any of the following methods to change to another layout:

- To revert the layout back to a default layout, click **View ➤ Reset to System Console Layout** or **View ➤ Reset to Toolkit Explorer Layout**.
- To set your workspace to a previously saved layout, click **View ➤ Custom Layouts**, and then select the custom layout.

4. To import, export, delete or rename custom layouts, click **View ➤ Custom Layouts ➤ Manage**. The **Manage Custom Layouts** dialog box opens and allows you to apply a variety of functions that facilitate custom layout management.

Figure 125. Manage Custom Layouts



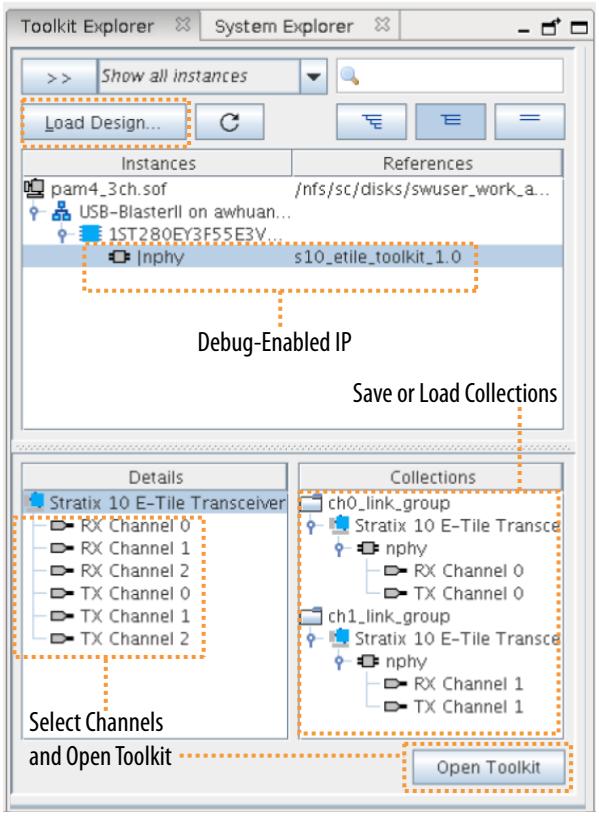
7.4. Launching a Toolkit in System Console

System Console provides the hardware debugging infrastructure to run the Available System Debugging Toolkits on page 175. When you load a design in the **Toolkit Explorer** that includes debug-enabled Intel FPGA IP, the **Toolkit Explorer** automatically lists the toolkits that are available for the IP in the design.

To launch a toolkit in System Console, follow these steps:

1. Create an Intel Quartus Prime project that includes debug-enabled Intel FPGA IP. Refer to IP Cores that Interact with System Console on page 160.
2. On the Compilation Dashboard, double-click **Assembler** to generate a `.sof` programming file for the design. Any prerequisite Compiler stages run automatically before the Assembler starts.
3. Launch System Console, as Starting System Console on page 162 describes.
4. In the **Toolkit Explorer**, click **Load Design**, and then select the `.sof` file that you create in step 2. When you load the design, **Toolkit Explorer** displays the debug-enabled IP instances.
5. Select a debug-enabled IP instance. The **Details** pane displays the channels that can launch toolkits.
6. To launch a toolkit, select the toolkit under **Details**. For toolkits with channels, you can also multi-select one or more channels from the **Details** pane. Then, click **Open Toolkit**. The toolkit opens in the **Main View**, and the **Collections** pane displays a collection of any channels that you select.
7. To save a collection for future use, right-click the collection, and then click **Export Collection.** To load a collection, right-click in the **Collections** pane, and then click **Import Collection**. By default, System Console creates a collection when you launch a toolkit.

Figure 126. Launching a Toolkit in System Console



Related Information

System Console and Toolkit Tcl Command Reference Manual

7.4.1. Available System Debugging Toolkits

The following toolkits are available to launch from the System Console **Toolkit Explorer** in the current version of the Intel Quartus Prime software.

Table 37. Toolkits Available in System Console Toolkit Explorer

Toolkit	Description	Toolkit Documentation
EMIF Calibration Debug Toolkit	Helps you to debug external memory interfaces by accessing calibration data obtained during memory calibration. The analysis tools can evaluate the stability of the calibrated interface and assess hardware conditions.	• *External Memory Interfaces Intel Agilex 7 FPGA IP User Guide* • *External Memory Interfaces Intel Stratix 10 FPGA IP User Guide*
EMIF Traffic Generator Configuration Toolkit	Helps you to debug external memory interfaces by sending sample traffic through the external memory interface to the memory device. The generated EMIF design example includes a traffic generator block with control and status registers.	

continued...

Toolkit	Description	Toolkit Documentation
EMIF Efficiency Monitor Toolkit	Helps you to debug external memory interfaces by measuring efficiency on the Avalon interface in real time. The generated EMIF design example can include the Efficiency Monitor block.	• *External Memory Interfaces Intel Agilex 7 FPGA IP User Guide* • *External Memory Interfaces Intel Stratix 10 FPGA IP User Guide*
Ethernet Toolkit	Helps you to interact with and debug an Ethernet Intel FPGA IP interface in real time. You can verify the status of the Ethernet link, assert and deassert IP resets, verifies the IP error correction capability,	*Ethernet Toolkit User Guide*
Intel Stratix 10 FPGA P-Tile Toolkit (for PCIe)	Helps you to optimize the performance of large-size data transfers with real-time control, monitoring, and debugging of the PCI Express* links at the Physical, Data Link, and Transaction layers.	*Intel FPGA P-Tile Avalon Memory Mapped IP for PCI Express* User Guide*
Serial Lite IV IP Toolkit	An inspection tool that monitors the status of a Serial Lite IV IP link and provides a step-by-step guide for the IP link initialization sequences.	• *Serial Lite IV Intel Agilex 7 FPGA IP Design Example User Guide* • *Serial Lite IV Intel Stratix 10 FPGA IP Design Example User Guide*
Intel Arria 10 and Intel Cyclone 10 GX Transceiver Native PHY Toolkit	Helps you to optimize high-speed serial links in your board design by providing real-time control, monitoring, and debugging of the transceiver links running on your board.	
L-Tile and H-Tile Transceiver Native PHY Toolkit		
E-Tile Transceiver Native PHY Toolkit		

The following legacy toolkits remain available by clicking **Tools ➤ Legacy Toolkits** in System Console. The legacy toolkits support earlier device families and may be subject to end of life and removal of support in a coming software release.

Table 38. Legacy Toolkits Available in System Console

Legacy Toolkit	Description	Legacy Toolkit Documentation
Ethernet Link Inspector - Link Monitor Toolkit	The Ethernet Link Inspector is an inspection tool that can continuously monitor an Ethernet link that contains an Ethernet IP. The Link Monitor toolkit performs real-time status monitoring of an Ethernet IP link. The link monitor continuously reads and displays all of the required status registers related to the Ethernet IP link, and displays the Ethernet IP link status at various stages are valid.	*Ethernet Link Inspector User Guide for Intel Stratix 10 Devices*
Ethernet Link Inspector - Link Analysis Toolkit	The Link Analysis toolkit displays a sequence of events on an Ethernet IP link, which occur in a finite duration of time. The Link Analysis requires the Signal Tap logic analyzer to first capture and store a database (`.csv`) of all required signals. The Link Analysis toolkit then performs an analysis on the database to extract all the required information and displays them in a user-friendly graphical user interface (GUI).	
S10 SDM Debug Toolkit	Provides access to current status of the Intel Stratix 10 device. To use these commands, you must have a valid design loaded that includes the module that you intend to access.	*Intel Stratix 10 Configuration User Guide*

Note: Refer to the toolkit documentation for individual toolkit launch, setup, and use information. The Transceiver Toolkit previously available in the Intel Quartus Prime software Tools menu is replaced by the Intel Arria 10 and Intel Cyclone 10 GX Transceiver Native PHY Toolkit.

7.4.2. Creating Collections from the Toolkit Explorer

You can create custom collections to view and configure members from different instances in a single Main View.

Perform these steps to group instances:

1. Select multiple items in the instances tree.
2. Right click to view the context-sensitive menu.
3. Select **Add to Collection ➤ New Collection**. The **Add to Collection** dialog box appears with members you select.

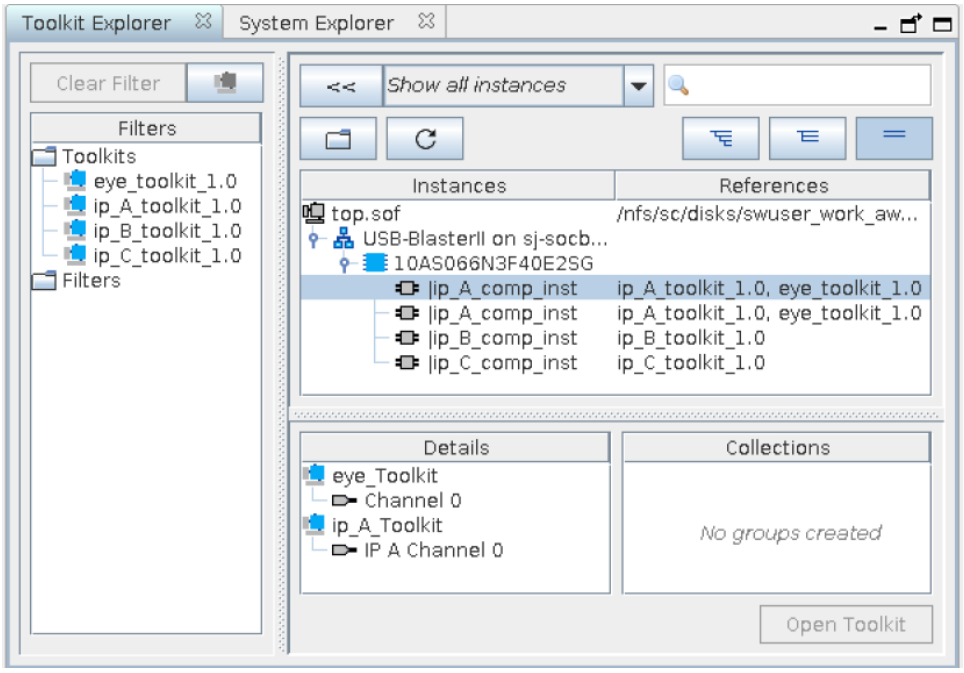
System Console adds the collections that you create to the **Collections** pane of the **Toolkit Explorer**. You can perform one of the following actions:

- Double-click on a custom-created collection to launch the Main view containing all of the group's members.
- Right-click on an existing collection member and select **Remove from Collection** to remove the member.

7.4.3. Filtering and Searching Interactive Instances

By default, the **Toolkits** list shows all toolkit instances and their respective channels linking to the System Console. This view is useful in simple cases, but can become very dense in a complex system having many debug-enabled IPs, and having potentially multiple FPGAs connected to System Console.

Figure 127. Toolkit Explorer with Filters



To limit the information display, the **Filter** list allows filtering the display by toolkit types currently available in the System Console. You can also create custom filters using groups, for example, "Inst A, Inst F, and Inst Z", or "E-Tile and L/H-Tile Transceivers only".

To refine the list of toolkits, use the search field in the **Toolkit Explorer** to filter the list further.

7.5. Using System Console Services

System Console services provide access to hardware modules that you instantiate in your FPGA. Services vary in the type of debug access they provide.

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.5.1. Locating Available Services

System Console uses a virtual file system to organize the available services, which is similar to the `/dev location` on Linux systems. Board connection, device type, and IP names are all part of a service path. Instances of services are referred to by their unique service path in the file system. To retrieve service paths for a particular service, use the command `get_service_paths` <*service-type*>.

Example 11. Locating a Service Path

```
#We are interested in master services.
set service_type "master"

#Get all the paths as a list.
```

```
set master_service_paths [get_service_paths $service_type]

#We are interested in the first service in the list.
set master_index 0

#The path of the first master.
set master_path [lindex $master_service_paths $master_index]

#Or condense the above statements into one statement:
set master_path [lindex [get_service_paths master] 0]
```

System Console commands require service paths to identify the service instance you want to access. The paths and indexes for different components can change between runs of System Console and between versions. Use the `get_service_paths` command to obtain service paths.

The string values of service paths change with different releases of the tool. Use the `marker_node_info` command to get information from the path.

System Console automatically discovers most services at startup. System Console automatically scans for all JTAG and USB-based service instances and retrieves their service paths. System Console does not automatically discover some services, such as TCP/IP. Use `add_service` to inform System Console about those services.

Example 12. Marker_node_info

Use the `marker_node_info` command to get information about SLD nodes associated with the specified service.

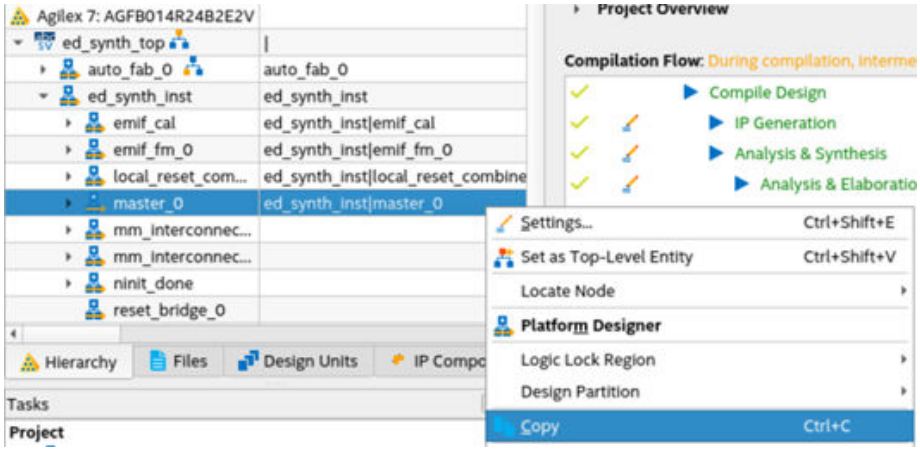
```
set slave_path [get_service_paths -type altera_avalon_uart.slave slave]
array set uart_info [marker_node_info $slave_path]
echo $uart_info(full_hpath)
```

Example 13. Locating the Correct Service Path

If the design contains multiple instances of the same service, it is necessary to use the full hierarchy path to correctly identify the service path.

In the following example, to identify the correct service path for a debug endpoint called `master_0`:

1. Locate the full hierarchy name of the endpoint in your design.



2. Right-click `master_0` and select **Copy** in the context-sensitive menu. This copies the full hierarchical path, (`ed_synth_top|master_0`).
3. Save this hierarchy path to a Tcl variable for easy reference later, as follows:

```
set desired_hpath ed_synth_inst|master_0
```

4. Use the `get_service_paths` command with the `–hpath` flag and the hierarchy path to obtain specific service path of the desired endpoint. The command returns a list with a service path.

```
#Return a list of one element with the desired element
set service_paths [get_service_paths -hpath $desired_hpath master]
```

5. Save the service path as a variable for easier access later.

```
#Extract and store the element in a variable
set master_0_spath [lindex $service_paths 0]
```

7.5.2. Opening and Closing Services

After you have a service path to a particular service instance, you can access the service for use.

The `claim_service` command directs System Console to start using a particular service instance, and with no additional arguments, claims a service instance for exclusive use.

Example 14. Opening a Service

```
set service_type "master"
set claim_path [claim_service $service_type $master_path mylib];#Claims service.
```

You can pass additional arguments to the `claim_service` command to direct System Console to start accessing a particular portion of a service instance. For example, if you use the master service to access memory, then use `claim_service` to only access the address space between `0x0` and `0x1000`. System Console then allows other users to access other memory ranges, and denies access to the claimed memory range. The `claim_service` command returns a newly created service path that you can use to access your claimed resources.

You can access a service after you open it. When you finish accessing a service instance, use the `close_service` command to direct System Console to make this resource available to other users.

Example 15. Closing a Service

```
close_service master $claim_path; #Closes the service.
```

7.5.3. Using the SLD Service

The SLD Service shifts values into the instruction and data registers of SLD nodes and captures the previous value. When interacting with a SLD node, start by acquiring exclusive access to the node on an opened service.

Example 16. SLD Service

```
set timeout_in_ms 1000
set lock_failed [sld_lock $sld_service_path $timeout_in_ms]
```

This code attempts to lock the selected SLD node. If it is already locked, `sld_lock` waits for the specified timeout. Confirm the procedure returns non-zero before proceeding. Set the instruction register and capture the previous one:

```
if {$lock_failed} {
    return
}
set instr 7
set delay_us 1000
set capture [sld_access_ir $sld_service_path $instr $delay_us]
```

The 1000 microsecond delay guarantees that the following SLD command executes at least 1000 microseconds later. Data register access works the same way.

```
set data_bit_length 32
set delay_us 1000
set data_bytes [list 0xEF 0xBE 0xAD 0xDE]
set capture [sld_access_dr $sld_service_path $data_bit_length $delay_us \
$data_bytes]
```

Shift count is specified in bits, but the data content is specified as a list of bytes. The capture return value is also a list of bytes. Always unlock the SLD node once finished with the SLD service.

```
sld_unlock $sld_service_path
```

Related Information

Virtual JTAG IP Core User Guide

7.5.3.1. SLD Commands

Table 39. SLD Commands

Command	Arguments	Function
`sld_access_ir`	*<claim-path>* *<ir-value>* *<delay>* (in µs)	Shifts the instruction value into the instruction register of the specified node. Returns the previous value of the instruction.

continued...

Command	Arguments	Function
		If the <*delay*> parameter is non-zero, then the JTAG clock is paused for this length of time after the access.
`sld_access_dr`	<*service-path*> <*size_in_bits*> <*delay-in-µs*>, <*list_of_byte_values*>	Shifts the byte values into the data register of the SLD node up to the size in bits specified. If the <*delay*> parameter is non-zero, then the JTAG clock is paused for at least this length of time after the access. Returns the previous contents of the data register.
`sld_lock`	<*service-path*> <*timeout-in-milliseconds*>	Locks the SLD chain to guarantee exclusive access. Returns 0 if successful. If the SLD chain is already locked by another user, tries for <*timeout*>ms before returning a Tcl error. You can use the catch command if you want to handle the error.
`sld_unlock`	<*service-path*>	Unlocks the SLD chain.

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.5.4. Using the In-System Sources and Probes Service

The In-System Sources and Probes (ISSP) service provides scriptable access to the In-System Sources and Probes Intel FPGA IP in a similar manner to using the **In-System Sources and Probes Editor** in the Intel Quartus Prime software.

Example 17. ISSP Service

Before you use the ISSP service, ensure your design works in the **In-System Sources and Probes Editor**. In System Console, open the service for an ISSP instance:

```
set issp_index 0
set issp [lindex [get_service_paths issp] 0]
set claimed_issp [claim_service issp $issp mylib]
```

View information about this particular ISSP instance:

```
array set instance_info [issp_get_instance_info $claimed_issp]
set source_width $instance_info(source_width)
set probe_width $instance_info(probe_width)
```

The Intel Quartus Prime software reads probe data as a single bitstring of length equal to the probe width:

```
set all_probe_data [issp_read_probe_data $claimed_issp]
```

As an example, you can define the following procedure to extract an individual probe line's data:

```
proc get_probe_line_data {all_probe_data index} {
    set line_data [expr { ($all_probe_data >> $index) & 1 }]
    return $line_data
}
set initial_all_probe_data [issp_read_probe_data $claim_issp]
set initial_line_0 [get_probe_line_data $initial_all_probe_data 0]
set initial_line_5 [get_probe_line_data $initial_all_probe_data 5]
# ...
set final_all_probe_data [issp_read_probe_data $claimed_issp]
set final_line_0 [get_probe_line_data $final_all_probe_data 0]
```

Similarly, the Intel Quartus Prime software writes source data as a single bitstring of length equal to the source width:

```
set source_data 0xDEADBEEF
issp_write_source_data $claimed_issp $source_data
```

You can also retrieve the currently set source data:

```
set current_source_data [issp_read_source_data $claimed_issp]
```

As an example, you can invert the data for a 32-bit wide source by doing the following:

```
set current_source_data [issp_read_source_data $claimed_issp]
set inverted_source_data [expr { $current_source_data ^ 0xFFFFFFFF }]
issp_write_source_data $claimed_issp $inverted_source_data
```

7.5.4.1. In-System Sources and Probes Commands

Note: The valid values for ISSP claims include `read_only`, `normal`, and `exclusive`.

Table 40. In-System Sources and Probes Commands

Command	Arguments	Function
`issp_get_instance_info`	*<service-path>*	Returns a list of the configurations of the In-System Sources and Probes instance, including: `instance_index` `instance_name` `source_width` `probe_width`
`issp_read_probe_data`	*<service-path>*	Retrieves the current value of the probe input. A hex string is returned representing the probe port value.
`issp_read_source_data`	*<service-path>*	Retrieves the current value of the source output port. A hex string is returned representing the source port value.
`issp_write_source_data`	*<service-path>* *<source-value>*	Sets values for the source output port. The value can be either a hex string or a decimal value supported by the System Console Tcl interpreter.

System Console and Toolkit Tcl Command Reference Manual

7.5.5. Using the Monitor Service

The monitor service builds on top of the host service to allow reads of Avalon memory-mapped interface agents at a regular interval. The service is fully software-based. The monitor service requires no extra soft-logic. This service streamlines the logic to do interval reads, and it offers better performance than exercising the host service manually for the reads.

Example 18. Monitor Service

1. Determine the host and the memory address range that you want to poll:

```
set master_index     0
set master [lindex [get_service_paths master] $master_index]
set address          0x2000
set bytes_to_read    100
set read_interval_ms 100
```

   With the first host, read 100 bytes starting at address 0x2000 every 100 milliseconds.

2. Open the monitor service:

```
set monitor [lindex [get_service_paths monitor] 0]
set claimed_monitor [claim_service monitor $monitor mylib]
```

   The monitor service opens the host service automatically.

3. With the monitor service, register the address range and time interval:

```
monitor_add_range $claimed_monitor $master $address $bytes_to_read
monitor_set_interval $claimed_monitor $read_interval_ms
```

4. Add more ranges, defining the result at each interval:

```
global monitor_data_buffer
set monitor_data_buffer [list]
```

5. Gather the data and append it with a global variable:

```
proc store_data {monitor master address bytes_to_read} {\
  global monitor_data_buffer
# monitor_read_data returns the range of data polled from the running \
  design as a list
#(in this example, a 100-element list).
  set data [monitor_read_data $claimed_monitor $master $address \
  $bytes_to_read]
# Append the list as a single element in the monitor_data_buffer \
  global list.
  lappend monitor_data_buffer $data
}
```

   Note: If this procedure takes longer than the interval period, the monitor service may have to skip the next one or more calls to the procedure. In this case, `monitor_read_data` returns the latest polled data.

6. Register this callback with the opened monitor service:

```
set callback [list store_data $claimed_monitor $master $address
$bytes_to_read]
monitor_set_callback $claimed_monitor $callback
```

7. Use the callback variable to call when the monitor finishes an interval. Start monitoring:

```
monitor_set_enabled $claimed_monitor 1
```

   Immediately, the monitor reads the specified ranges from the device and invokes the callback at the specified interval. Check the contents of `monitor_data_buffer` to verify this. To turn off the monitor, use 0 instead of 1 in the above command.

7.5.5.1. Monitor Commands

You can use the Monitor commands to read many Avalon memory-mapped interface agent memory locations at a regular interval.

Under normal load, the monitor service reads the data after each interval and then calls the callback. If the value you read is timing sensitive, you can use the `monitor_get_read_interval` command to read the exact time between the intervals at which the data was read.

Under heavy load, or with a callback that takes a long time to execute, the monitor service skips some callbacks. If the registers you read do not have side effects (for example, they read the total number of events since reset), skipping callbacks has no effect on your code. The `monitor_read_data` command and `monitor_get_read_interval` command are adequate for this scenario.

If the registers you read have side effects (for example, they return the number of events since the last read), you must have access to the data that was read, but for which the callback was skipped. The `monitor_read_all_data` and `monitor_get_all_read_intervals` commands provide access to this data.

Table 41. Monitoring Commands

Command	Arguments	Function
`monitor_add_range`	*<service-path>* *<target-path>* *<address>* *<size>*	Adds a contiguous memory address into the monitored memory list. *<service path>* is the value returned when you opened the service. *<target-path>* argument is the name of a host service to read. The address is within the address space of this service. *<target-path>* is returned from `[lindex [get_service_paths master] n]` where *n* is the number of the host service. *<address>* and *<size>* are relative to the host service.
`monitor_get_all_read_intervals`	*<service-path>* *<target-path>* *<address>* *<size>*	Returns a list of intervals in milliseconds between two reads within the data returned by `monitor_read_all_data`.
`monitor_get_interval`	*<service-path>*	Returns the current interval set which specifies the frequency of the polling action.
`monitor_get_missing_event_count`	*<service-path>*	Returns the number of callback events missed during the evaluation of last Tcl callback expression.
`monitor_get_read_interval`	*<service-path>* *<target-path>* *<address>* *<size>*	Returns the milliseconds elapsed between last two data reads returned by `monitor_read_data`.
`monitor_read_all_data`	*<service-path>* *<target-path>* *<address>* *<size>*	Returns a list of 8-bit values read from all recent values read from device since last Tcl callback. You must specify a memory range within the range in `monitor_add_range`.

continued...

Command	Arguments	Function
`monitor_read_data`	*<service-path>* *<target-path>* *<address>* *<size>*	Returns a list of 8-bit values read from the most recent values read from device. You must specify a memory range within the range in `monitor_add_range`.
`monitor_set_callback`	*<service-path>* *<Tcl-expression>*	Specifies a Tcl expression that the System Console must evaluate after reading all the memories that this service monitors. Typically, you specify this expression as a single string Tcl procedure call with necessary argument passed in.
`monitor_set_enabled`	*<service-path>* *<enable(1)/disable(0)>*	Enables and disables monitoring. Memory read starts after this command, and Tcl callback evaluates after data is read.
`monitor_set_interval`	*<service-path>* *<interval>*	Defines the target frequency of the polling action by specifying the interval between two memory reads. The actual polling frequency varies depending on the system activity.

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.5.6. Using the Device Service

The device service supports device-level actions.

Example 19. Programming

You can use the device service with Tcl scripting to perform device programming:

```
set device_index 0 ; #Device index for target
set device [lindex [get_service_paths device] $device_index]
set sof_path [file join project_path output_files project_name.sof]
device_download_sof $device $sof_path
```

To program, all you need are the device service path and the file system path to a `.sof`. Ensure that no other service (e.g. host service) is open on the target device or else the command fails. Afterwards, you may do the following to check that the design linked to the device is the same one programmed:

```
device_get_design $device
```

7.5.6.1. Device Commands

The device commands provide access to programmable logic devices on your board. Before you use these commands, identify the path to the programmable logic device on your board using the `get_service_paths`.

Table 42. Device Commands

Command	Arguments	Function
`device_download_sof`	*<service_path>* *<sof-file-path>*	Loads the specified `.sof` to the device specified by the path.
`device_get_connections`	*<service_path>*	Returns all connections which go to the device at the specified path.
`device_get_design`	*<device_path>*	Returns the design this device is currently linked to.

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.5.7. Using the Design Service

You can use design service commands to work with Intel Quartus Prime design information.

Example 20. Load

When you open System Console from the Intel Quartus Prime software, the current project's debug information is sourced automatically if the `.sof` file is present. In other situations, you can load the `.sof` manually.

```
set sof_path [file join project_dir output_files project_name.sof]
set design [design_load $sof_path]
```

System Console is now aware of the `.sof` loading.

Example 21. Linking

Once a `.sof` loads, System Console automatically links design information to the connected device. The link persists and you can unlink or reuse the link on an equivalent device with the same `.sof`.

You can perform manual linking as follows:

```
set device_index 0; # Device index for our target
set device [lindex [get_service_paths device] $device_index]
design_link $design $device
```

Manual linking fails if the target device does not match the design service.

Linking fails even if the `.sof` programmed to the target is not the same as the design `.sof`.

7.5.7.1. Design Service Commands

Design service commands load and work with your design at a system level.

Table 43. Design Service Commands

Command	Arguments	Function
`design_load`	*<quartus-project-path>*, *<sof-file-path>*, or *<qpf-file-path>*	Loads a model of an Intel Quartus Prime design into System Console. Returns the design path. For example, if your Intel Quartus Prime Project File (`.qpf`) is in `c:/projects/loopback`, type the following command: `design_load {c:\projects\loopback\}`
`design_link`	*<design-path>* *<device-service-path>*	Links an Intel Quartus Prime logical design with a physical device. For example, you can link an Intel Quartus Prime design called **2c35_quartus_design** to a 2c35 device. After you create this link, System Console creates the appropriate correspondences between the logical and physical submodules of the Intel Quartus Prime project.
`design_extract_debug_files`	*<design-path>* *<zip-file-name>*	Extracts debug files from a `.sof` to a zip file which can be emailed to *Intel FPGA Support* for analysis.

continued...

Command	Arguments	Function
		You can specify a design path of {} to unlink a device and to disable auto linking for that device.
design_get_warnings	*<design-path>*	Gets the list of warnings for this design. If the design loads correctly, then an empty list returns.

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.5.8. Using the Bytestream Service

The bytestream service provides access to modules that produce or consume a stream of bytes. Use the bytestream service to communicate directly to the IP core that provides bytestream interfaces, such as the JTAG UART or the Avalon Streaming JTAG interface Intel FPGA IP.

Example 22. Bytestream Service

The following code finds the bytestream service for your interface and opens it:

```
set bytestream_index 0
set bytestream [lindex [get_service_paths bytestream] $bytestream_index]
set claimed_bytestream [claim_service bytestream $bytestream mylib]
```

To specify the outgoing data as a list of bytes and send it through the opened service:

```
set payload [list 1 2 3 4 5 6 7 8]
bytestream_send $claimed_bytestream $payload
```

Incoming data also comes as a list of bytes:

```
set incoming_data [list]
while {[llength $incoming_data] ==0} {
    set incoming_data [bytestream_receive $claimed_bytestream 8]
}
```

Close the service when done:

```
close_service bytestream $claimed_bytestream
```

7.5.8.1. Bytestream Commands

Table 44. Bytestream Commands

Command	Arguments	Function
bytestream_send	*<service-path>* *<values>*	Sends the list of bytes to the specified bytestream service. Values argument is the list of bytes to send.
bytestream_receive	*<service-path>* *<length>*	Returns a list of bytes currently available in the specified services receive queue, up to the specified limit. Length argument is the maximum number of bytes to receive.

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.5.9. Using the JTAG Debug Service

The JTAG Debug service allows you to check the state of clocks and resets within your design.

The following is a JTAG Debug design flow example.

1. To identify available JTAG Debug paths:

```
get_service_paths jtag_debug
```

2. To select a JTAG Debug path:

```
set jtag_debug_path [lindex [get_service_paths jtag_debug] 0]
```

3. To claim a JTAG Debug service path:

```
 set claim_jtag_path [claim_service jtag_debug$jtag_debug_path mylib]
```

4. Running the JTAG Debug service:

```
jtag_debug_reset_system $claim_jtag_path
jtag_debug_loop $claim_jtag_path [list 1 2 3 4 5]
```

7.5.9.1. JTAG Debug Commands

JTAG Debug commands help debug the JTAG Chain connected to a device.

Table 45. JTAG Debug Commands

Command	Argument	Function
`jtag_debug_loop`	*<service-path> <list_of_byte_values>*	Loops the specified list of bytes through a loopback of `tdi` and `tdo` of a system-level debug (SLD) node. Returns the list of byte values in the order that they were received. This command blocks until all bytes are received. Byte values have the `0x` (hexadecimal) prefix and are delineated by spaces.
`jtag_debug_sample_clock`	*<service-path>*	Returns the clock signal of the system clock that drives the module's system interface. The clock value is sampled asynchronously; consequently, you must sample the clock several times to guarantee that it is switching.
`jtag_debug_sample_reset`	*<service-path>*	Returns the value of the `reset_n` signal of the Avalon-ST JTAG Interface core. If `reset_n` is low (asserted), the value is 0 and if `reset_n` is high (deasserted), the value is 1.
`jtag_debug_sense_clock`	*<service-path>*	Returns a sticky bit that monitors system clock activity. If the clock switched at least once since the last execution of this command, returns 1. Otherwise, returns 0.. The sticky bit is reset to 0 on read.
`jtag_debug_reset_system`	*<service-path>*	Issues a reset request to the specified service. Connectivity within your device determines which part of the system is reset.

System Console and Toolkit Tcl Command Reference Manual

7.6. On-Board Intel FPGA Download Cable II Support

System Console supports an On-Board Intel FPGA Download Cable II circuit via the USB Debug Master IP component. This IP core supports the master service.

7.7. MATLAB and Simulink* in a System Verification Flow

You can test system development in System Console using MATLAB and Simulink*, and set up a system verification flow using the Intel FPGA Hardware in the Loop (HIL) tools. In this approach, you deploy the design hardware to run in real time, and simulate the system's surrounding components in a software environment. The HIL approach allows you to use the flexibility of software tools with the real-world accuracy and speed of hardware. You can gradually introduce more hardware components to the system verification testbench. This technique gives you more control over the integration process as you tune and validate the system. When the full system is integrated, the HIL approach allows you to provide stimuli via software to test the system under a variety of scenarios.

Advantages of HIL Approach

- Avoid long computational delays for algorithms with high processing rates
- API helps to control, debug, visualize, and verify FPGA designs all within the MATLAB environment
- FPGA results are read back by the MATLAB software for further analysis and display

Required Tools and Components

- MATLAB software
- DSP Builder for Intel FPGAs software
- Intel Quartus Prime software
- Intel FPGA

Note: The DSP Builder for Intel FPGAs installation bundle includes the System Console MATLAB API.

Figure 128. Hardware in the Loop Host-Target Setup

Related Information

Hardware in the Loop from the MATLAB Simulink Environment white paper

7.7.1. Supported MATLAB API Commands

You can perform the work from the MATLAB environment, and read and write to hosts and agents through the System Console. The supported MATLAB API commands do not require launching the System Console GUI. The supported commands are:

- `SystemConsole.refreshMasters;`
- `M = SystemConsole.openMaster(1);`
- `M.write (type, byte address, data);`
- `M.read (type, byte address, number of words);`
- `M.close`

Example 23. MATLAB API Script Example

```
SystemConsole.refreshMasters; %Investigate available targets
M = SystemConsole.openMaster(1); %Creates connection with FPGA target
%%%%%%%% User Application %%%%%%%%%%%%
....
M.write('uint32',write_address,data); %Send data to FPGA target
....
data = M.read('uint32',read_address,size); %Read data from FPGA target
....
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
M.close; %Terminates connection to FPGA target
```

7.7.2. High Level Flow

1. Install the DSP Builder for Intel FPGAs software, so you have the necessary libraries to enable this flow
2. Build the design using Simulink and the DSP Builder for Intel FPGAs libraries.

   DSP Builder for Intel FPGAs helps to convert the Simulink design to HDL
3. Include Avalon memory mapped components in the design (DSP Builder for Intel FPGAs can port non-Avalon memory mapped components)
4. Include Signals and Control blocks in the design
5. Separate synthesizable and non-synthesizable logic with boundary blocks.
6. Integrate the DSP system in Platform Designer
7. Program the Intel FPGA
8. Interact with the Intel FPGA through the supported MATLAB API commands.

7.8. System Console Examples and Tutorials

Intel provides examples for performing board bring-up, creating a simple toolkit, and programming a Nios II processor. The `System_Console.zip` file contains design files for the board bring-up example. The Nios II Ethernet Standard `.zip` files contain the design files for the Nios II processor example.

Note: The instructions for these examples assume that you are familiar with the Intel Quartus Prime software, Tcl commands, and Platform Designer.

Related Information

On-Chip Debugging Design Examples Website
Contains the design files for the example designs that you can download.

7.8.1. Nios II Processor Example

This example programs the Nios II processor on your board to run the count binary software example included in the Nios II installation. This is a simple program that uses an 8-bit variable to repeatedly count from 0x00 to 0xFF. The output of this variable is displayed on the LEDs on your board. After programming the Nios II processor, you use System Console processor commands to start and stop the processor.

To run this example, perform the following steps:

1. Download the Nios II Ethernet Standard Design Example for your board from the Intel website.
2. Create a folder to extract the design. For this example, use `C:\Count_binary`.
3. Unzip the Nios II Ethernet Standard Design Example into `C:\Count_binary`.
4. In a Nios II command shell, change to the directory of your new project.
5. Program your board. In a Nios II command shell, type the following:

```
nios2-configure-sof niosii_ethernet_standard_<board_version>.sof
```

6. Using Nios II Software Build Tools for Eclipse, create a new Nios II Application and BSP from Template using the **Count Binary** template and targeting the Nios II Ethernet Standard Design Example.
7. To build the executable and linkable format (ELF) file (`.elf`) for this application, right-click the **Count Binary** project and select **Build Project**.
8. Download the `.elf` file to your board by right-clicking **Count Binary** project and selecting **Run As ➤ Nios II Hardware**.
   - The LEDs on your board provide a new light show.
9. Type the following:

```
system-console; #Start System Console.

#Set the processor service path to the Nios II processor.
set niosii_proc [lindex [get_service_paths processor] 0]

set claimed_proc [claim_service processor $niosii_proc mylib]; #Open the
service.

processor_stop $claimed_proc; #Stop the processor.
#The LEDs on your board freeze.

processor_run $claimed_proc; #Start the processor.
#The LEDs on your board resume their previous activity.

processor_stop $claimed_proc; #Stop the processor.

close_service processor $claimed_proc; #Close the service.
```

- The `processor_step`, `processor_set_register`, and `processor_get_register` commands provide additional control over the Nios II processor.

Related Information

- Nios II Ethernet Standard Design Example
- Nios II Gen2 Software Developer's Handbook

7.8.1.1. Processor Commands

Table 46. Processor Commands

Command [2]	Arguments	Function
`processor_download_elf`	*<service-path>* *<elf-file-path>*	Downloads the given Executable and Linking Format File (`.elf`) to memory using the master service associated with the processor. Sets the processor's program counter to the `.elf` entry point.
`processor_in_debug_mode`	*<service-path>*	Returns a non-zero value if the processor is in debug mode.
`processor_reset`	*<service-path>*	Resets the processor and places it in debug mode.
`processor_run`	*<service-path>*	Puts the processor into run mode.
`processor_stop`	*<service-path>*	Puts the processor into debug mode.
`processor_step`	*<service-path>*	Executes one assembly instruction.
`processor_get_register_names`	*<service-path>*	Returns a list with the names of all of the processor's accessible registers.
`processor_get_register`	*<service-path>* *<register_name>*	Returns the value of the specified register.
`processor_set_register`	*<service-path>* *<register_name>* *<value>*	Sets the value of the specified register.

Related Information

Nios II Processor Example on page 192

7.9. Running System Console in Command-Line Mode

You can run System Console in command line mode and either work interactively or run a Tcl script. System Console prints the output in the console window.

(2) If your system includes a Nios II/f core with a data cache, it may complicate the debugging process. If you suspect the Nios II/f core writes to memory from the data cache at nondeterministic intervals; thereby, overwriting data written by the System Console, you can disable the cache of the Nios II/f core while debugging.

- `--cli`—Runs System Console in command-line mode.
- `--project_dir=<project dir>`—Directs System Console to the location of your hardware project. Also works in GUI mode.
- `--script=<your script>.tcl`—Directs System Console to run your Tcl script.
- `--help`— Lists all available commands. Typing `--help` <*command name*> provides the syntax and arguments of the command.

System Console provides command completion if you type the beginning letters of a command and then press the **Tab** key.

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.10. Using System Console Commands

You can use System Console commands to control hardware debug and testing with the command-line or scripting. Use System Console commands to identify a System Console service by its path, to open and close a connection, add a service, and a variety of other System Console controls.

Note: For a complete reference of currently supported System Console and toolkit commands, refer to the *System Console and Toolkit Tcl Command Reference Manual*.

The following steps show initiation of a simple service connection:

1. Identify a service by specifying its path with the `get_service_paths` command.
2. Open a connection to the service with the `claim_service` command.
3. Use Tcl and System Console commands to test the connected device.
4. Close a connection to the service with the `close_service` command

Related Information

System Console and Toolkit Tcl Command Reference Manual

7.11. Using Toolkit Tcl Commands

For advanced users, System Console also supports Tcl commands that allow you to define and operate your own custom toolkits.

You can use the Toolkit Tcl commands to add and set the toolkit requirements and properties, and to retrieve accessible toolkit modules, systems, and services at the command-line or with scripting.

Note: For a complete reference of currently supported System Console and toolkit commands, refer to the *System Console and Toolkit Tcl Command Reference Manual*.

7.12. Analyzing and Debugging Designs with the System Console Revision History

The following revision history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.10.02	23.3	• Updated product family name to "Intel Agilex 7." • Revised the existing information and added a new example on how to locate the correct service path using full hierarchy name in *Locating Available Services* topic.
2022.12.12	22.4	• Added new *Customizing, Saving, and Resetting the System Console Layout* topic for new layout manager feature.
2022.07.08	22.1	• Fixed broken links in the following topics: — "Introduction to System Console" — "MATLAB and Simulink* in a System Verification Flow" — "System Console Example" — "Nios II Gen 2 Processor Example"
2021.06.21	21.2	• Moved System Console and Toolkit Tcl command descriptions to *System Console and Toolkit Tcl Command Reference Manual* and provided links to this new comprehensive document. • Replaced non-inclusive terms with "host" and "agent" inclusive terms for Avalon memory mapped interface descriptions and related GUI elements. • Added toolkit definition to *Introduction to System Console* topic. • Revised *System Console Tools* figure. • Revised wording of *Autosweep View* topic for clarity. • Added details to explanation of legacy toolkits in *Available System Debugging Toolkits* • Added ISSP service to *Common Services for System Console* table. • Added link to download center.
2020.09.28	20.3	• Revised "Introduction to System Console" wording and block diagram. • Revised "Starting System Console" to consolidate all methods. • Revised "Toolkit Explorer Pane" to refer to launching toolkits. • Revised "Autosweep View" to account for use with or without toolkit and export and import of settings. • Added new "Launching a Toolkit in System Console" topic. • Added new "Available System Debugging Toolkits" topic. • Added new Toolkit Tcl Commands section. • Reordered some topics and updated outdated screenshots.
2019.09.30	19.3	Made the following updates in the *Analyzing and Debugging Designs with System Console* chapter:

continued...

Document Version	Intel Quartus Prime Version	Changes
		• Updated *System Console GUI* and *System Explorer Pane* topics to describe the new framework. • Added the following new topics to describe various panes and views added to the System Console: — *System Console Default Panes* — *Toolkit Explorer Pane* — *Filtering and Searching Interactive Instances* — *Creating Collections from the Toolkit Explorer* — *System Console Views* — *Main View* — *Link Pair View* — *Autosweep View* — *Dashboard View* — *Eye View* • Removed *Working with Toolkit* section completely since it was now outdated due to the implementation of new System Console framework.
2018.05.07	18.0.0	Removed obsolete section: *Board Bring-Up with System Console Tutorial*.
2017.05.08	17.0.0	• Created topic *Convert your Dashboard Scripts to Toolkit API*. • Removed *Registering the Service* Example from *Toolkit API Script Examples*, and added corresponding code snippet to *Registering a Toolkit*. • Moved *.toolkit Description File Example* under *Creating a Toolkit Description File*. • Renamed *Toolkit API GUI Example .toolkit File* to *.toolkit Description File Example*. • Updated examples on Toolkit API to reflect current supported syntax.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2015.11.02	15.1.0	• Edits to Toolkit API content and command format. • Added Toolkit API design example. • Added graphic to *Introduction to System Console*. • Deprecated Dashboard. • Changed instances of *Quartus II* to *Intel Quartus Prime*.
October 2015	15.1.0	• Added content for Toolkit API — Required .toolkit and Tcl files — Registering and launching the toolkit — Toolkit discovery and matching toolkits to IP — Toolkit API commands table
May 2015	15.0.0	Added information about how to download and start System Console stand-alone.
December 2014	14.1.0	• Added overview and procedures for using ADC Toolkit on MAX 10 devices. • Added overview for using MATLAB/Simulink Environment with System Console for system verification.
June 2014	14.0.0	Updated design examples for the following: board bring-up, dashboard service, Nios II processor, design service, device service, monitor service, bytestream service, SLD service, and ISSP service.
November 2013	13.1.0	Re-organization of sections. Added high-level information with block diagram, workflow, SLD overview, use cases, and example Tcl scripts.
June 2013	13.0.0	Updated Tcl command tables. Added board bring-up design example. Removed SOPC Builder content.

continued...

Document Version	Intel Quartus Prime Version	Changes
November 2012	12.1.0	Re-organization of content.
August 2012	12.0.1	Moved Transceiver Toolkit commands to Transceiver Toolkit chapter.
June 2012	12.0.0	Maintenance release. This chapter adds new System Console features.
November 2011	11.1.0	Maintenance release. This chapter adds new System Console features.
May 2011	11.0.0	Maintenance release. This chapter adds new System Console features.
December 2010	10.1.0	Maintenance release. This chapter adds new commands and references for Qsys.
July 2010	10.0.0	Initial release. Previously released as the System Console User Guide, which is being obsoleted. This new chapter adds new commands.

Related Information

- Intel Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Intel Quartus Prime Pro Edition software, including managing Intel Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Intel Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Intel Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Intel Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Intel Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Intel Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Intel Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Intel Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Intel Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Intel Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Intel Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Intel Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Intel Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Intel Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys* that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Intel Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys*. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Intel Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Intel Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Intel Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Intel Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Intel Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Intel Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Intel Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Intel Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Intel Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Intel Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Intel Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

1. Timing Analysis Introduction

Comprehensive timing analysis of your design allows you to validate circuit performance, identify timing violations, and drive the Fitter's placement of logic to meet your timing goals. The Quartus® Prime Timing Analyzer uses industry-standard constraint and analysis methodology to report on all data required times, data arrival times, and clock arrival times for all register-to-register, I/O, and asynchronous reset paths in your design.

The Timing Analyzer verifies that your design meets all required timing relationships to correctly function, and confirms actual signal arrival times against the constraints that you specify. This user guide provides an introduction to basic timing analysis concepts, along with step-by-step instructions for using the Quartus Prime Timing Analyzer.

1.1. What's New In This Version

- Updated throughout to reflect recent added support for DNI-related SDC-on-RTL constraints and post-synthesis Early Timing Analysis.
- Some timing reports now support opening the reported source file in a text editor, as Report Timing By Source Files describes.
- For change details, refer to the chapter revision histories in this document.

1.2. Timing Analysis Basic Concepts

This user guide introduces the following concepts to describe timing analysis:

Table 1. Timing Analyzer Terminology

Term	Definition
Arrival time	The Timing Analyzer calculates the data and clock arrival time versus the required time at register pins.
Cell	Device resource that contains look-up tables (LUT), registers, digital signal processing (DSP) blocks, memory blocks, or I/O elements. In Stratix® series devices, the LUTs and registers are contained in logic elements (LE) modeled as cells.
Clock	Named signal representing clock domains inside or outside of your design.
Clock-as-data analysis	More accurate timing analysis for complex paths that includes any phase shift associated with a PLL for the clock path, and considers any related phase shift for the data path.
Clock hold time	Minimum time interval that a signal must be stable on the input pin that feeds a data input or clock enable, after an active transition on the clock input.

continued...

Term	Definition
Clock launch and latch edge	The launch edge is the clock edge that sends data out of a register or other sequential element, and acts as a source for the data transfer. The latch edge is the active clock edge that captures data at the data port of a register or other sequential element, acting as a destination for the data transfer.
Clock pessimism	Clock pessimism refers to use of the maximum (rather than minimum) delay variation associated with common clock paths during static timing analysis.
Clock setup time	Minimum time interval between the assertion of a signal at a data input, and the assertion of a low-to-high transition on the clock input.
Maximum or minimum delay constraint	A constraint that specifies timing path analysis with a non-default setup or hold relationship.
Net	A collection of two or more interconnected components.
Node	Represents a wire carrying a signal that travels between different logical components in the design. Most basic timing netlist unit. Used to represent ports, pins, and registers.
Pin	Inputs or outputs of cells.
Port	Top-level module inputs or outputs; for example, a device pin.
Metastability	Metastability problems can occur when a signal transfers between circuitry in unrelated or asynchronous clock domains. The Timing Analyzer analyzes the potential for metastability in your design and can calculate the MTBF for synchronization register chains.
Multicorner analysis	Timing analysis of slow and fast timing corners to verify your design under a variety of voltage, process, and temperature operating conditions.
Multicycle paths	A data path that requires a non-default number of clock cycles for proper analysis.
Recovery and removal time	Recovery time is the minimum length of time for the deassertion of an asynchronous control signal relative to the next clock edge. Removal time is the minimum length of time the deassertion of an asynchronous control signal must be stable after the active clock edge.
Timing netlist	A Compiler-generated list of your design's synthesized nodes and connections. The Timing Analyzer requires this netlist to perform timing analysis.
Timing path	The wire connection (net) between any two sequential design nodes, such as the output of a register to the input of another register.

1.2.1. Timing Path and Clock Analysis

The Timing Analyzer measures the timing performance for all timing paths identified in your design. Prior to running full timing analysis, you can run post-synthesis early timing analysis to obtain an early view of the design core timing. For post-fit timing analysis, the Timing Analyzer requires a timing netlist that describes your design's nodes and connections for analysis and uses routing delays between core blocks represented by average interconnect delays. The post-synthesis timing delays reflect the delays of each type of connected core block.

Post-fit timing analysis also determines clock relationships for all register-to-register transfers in your design by analyzing the clock setup and hold relationship between the launch edge and latch edge of the clock.

1.2.1.1. The Timing Netlist

The Timing Analyzer uses the timing netlist data to determine the data and clock arrival time versus required time for all timing paths in the design. Post-synthesis timing analysis utilizes a timing netlist that incorporates core blocks (including their

internal logic) and peripheral blocks (excluding their internal details). The Timing Analyzer estimates pre-synthesis routing delays by using an average interconnect model that the Analysis & Elaboration compilation stage generates. You can generate the post-fit timing netlist in the Timing Analyzer any time after running the Fitter.

The following figures illustrate division of a simple design schematic into timing netlist delays.

Figure 1. Simple Design Schematic

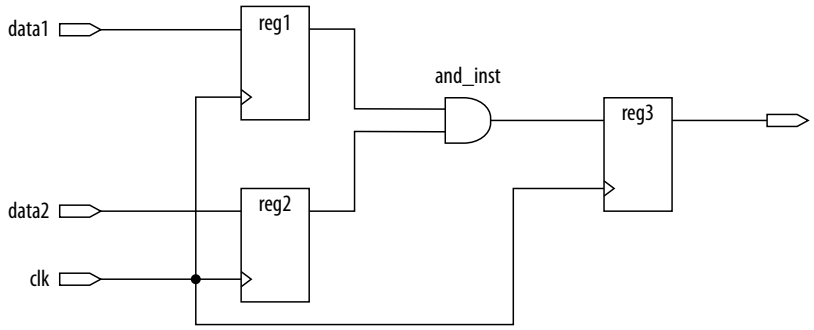

Figure 2. Division of Elements into Timing Netlist Delays

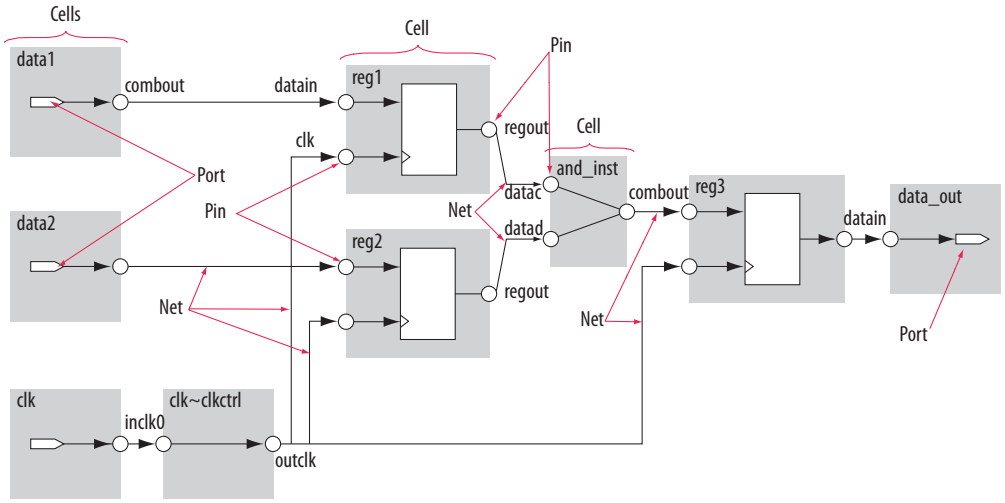


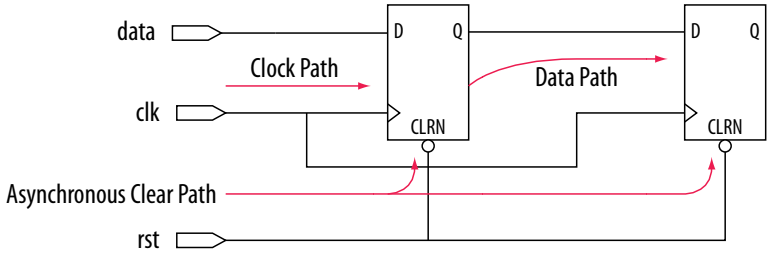
1.2.1.2. Timing Paths

Timing paths connect two design nodes, such as the output of a register to the input of another register.

Understanding the types of timing paths is important to timing closure and optimization. The Timing Analyzer recognizes and analyzes the following timing paths:

- **Edge paths**—connections from ports-to-pins, from pins-to-pins, and from pins-to-ports.
- **Clock paths**—connections from device ports or internally generated clock pins to the clock pin of a register.
- **Data paths**—connections from a port or the data output pin of a sequential element to a port or the data input pin of another sequential element.
- **Asynchronous paths**—connections from a port or asynchronous pins of another sequential element such as an asynchronous reset or asynchronous clear.

Figure 3. Path Types Commonly Analyzed by the Timing Analyzer



In addition to identifying various paths in a design, the Timing Analyzer analyzes clock characteristics to compute the worst-case requirement between any two registers in a single register-to-register path. You must constrain all clocks in your design before analyzing clock characteristics.

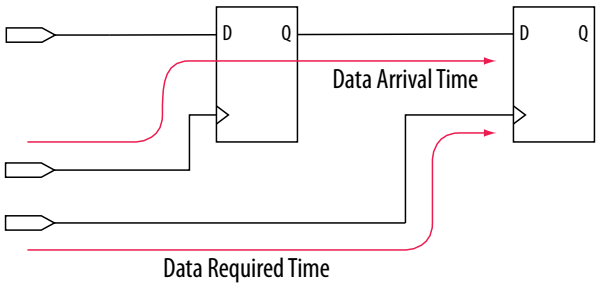
1.2.1.3. Data and Clock Arrival Times

After the Timing Analyzer identifies the path type, the Timing Analyzer can report data and clock arrival times at register pins.

The Timing Analyzer calculates data arrival time by adding the launch edge time to the delay from the clock source to the clock pin of the source register, the micro clock-to-output delay (μt_{CO}) of the source register, and the delay from the source register's data output (Q) to the destination register's data input (D).

The Timing Analyzer calculates data required time by adding the latch edge time to the sum of all delays between the clock port and the clock pin of the destination register. It includes any clock port buffer delays and subtracts the micro setup time (μt_{SU}) (or adds the micro hold time) of the destination register. Where the μt_{SU} is the intrinsic setup time of an internal register in the FPGA.

Figure 4. Data Arrival and Data Required Times



The basic calculations for data arrival and data required times including the launch and latch edges.

Figure 5. Data Arrival and Data Required Time Equations

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Source Clock Delay} + \mu t_{CO} + \text{Register-to-Register Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Destination Clock Delay} - \mu t_{SU}$$

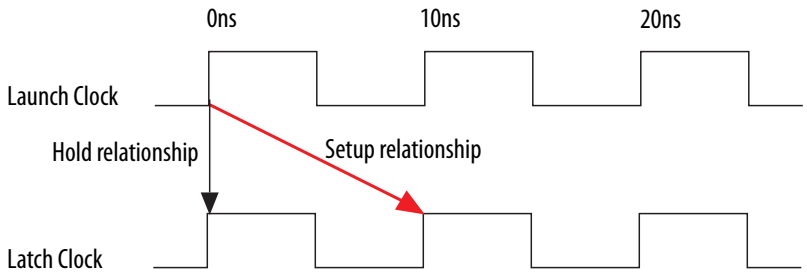
1.2.1.4. Launch and Latch Edges

All timing analysis requires the presence of one or more clock signals. The Timing Analyzer determines clock relationships for all register-to-register transfers in your design by analyzing the clock setup and hold relationship between the launch edge and latch edge of the clock.

The launch edge of the clock signal is the clock edge that sends data out of a register or other sequential element, and acts as a source for the data transfer. The latch edge is the active clock edge that captures data at the data port of a register or other sequential element, acting as a destination for the data transfer.

Figure 6. Setup and Hold Relationship for Launch and Latch Edges 10ns Apart

In this example, the launch edge sends the data from register `reg1` at 0 ns, and the register `reg2` captures the data when triggered by the latch edge at 10 ns. The data arrives at the destination register before the next latch edge.



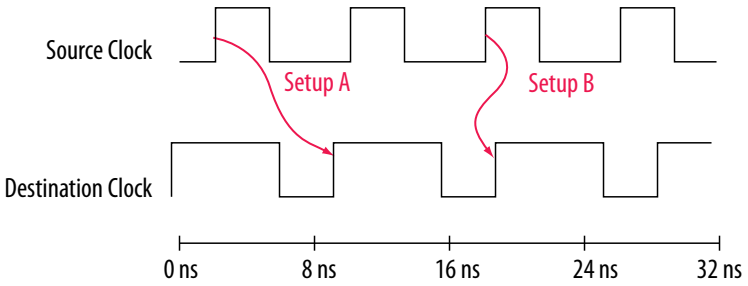
You must define all clocks in your design by assigning a clock constraint to each clock source node. These clock constraints provide the structure required for repeatable data relationships. If you do not constrain the clocks in your design, the Quartus Prime software analyzes all clocks as 1 GHz clocks to maximize timing based Fitter effort. To ensure realistic slack values, you must constrain all clocks in your design with real values.

1.2.2. Clock Setup Analysis

To perform a clock setup check, the Timing Analyzer determines a setup relationship by analyzing each launch and latch edge for each register-to-register path.

For each latch edge at the destination register, the Timing Analyzer uses the closest previous clock edge at the source register as the launch edge. The following figure shows two setup relationships, setup A and setup B. For the latch edge at 10 ns, the closest clock that acts as a launch edge is at 3 ns and has the setup A label. For the latch edge at 20 ns, the closest clock that acts as a launch edge is 19 ns and has the setup B label. The Timing Analyzer analyzes the most restrictive setup relationship, in this case setup B; if that relationship meets the design requirement, then setup A meets the requirement by default.

Figure 7. Setup Check



The Timing Analyzer reports the result of clock setup checks as slack values. Slack is the margin by which a circuit meets or does not meet the timing requirement. Positive slack indicates the margin by the circuit meets the requirement. Negative slack indicates the margin by which the circuit does not meet the requirement.

Figure 8. Clock Setup Slack for Internal Register-to-Register Paths

$$\begin{aligned}\text{Clock Setup Slack} &= \text{Data Required Time} - \text{Data Arrival Time}\\ \text{Data Arrival Time} &= \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}\\ \text{Data Required Time} &= \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU} - \text{Setup Uncertainty}\end{aligned}$$

The Timing Analyzer performs setup checks using the maximum delay when calculating data arrival time, and minimum delay when calculating data required time. Some of the spread between maximum arrival path delays and minimum required path delays may be recoverable with path pessimism removal, as Timing Pessimism on page 16 describes.

Figure 9. Clock Setup Slack from Input Port to Internal Register

$$\begin{aligned}\text{Clock Setup Slack} &= \text{Data Required Time} - \text{Data Arrival Time}\\ \text{Data Arrival Time} &= \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Maximum Delay} + \text{Port-to-Register Delay}\\ \text{Data Required Time} &= \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU} - \text{Setup Uncertainty}\end{aligned}$$

Figure 10. Clock Setup Slack from Internal Register to Output Port

$$\begin{aligned}\text{Clock Setup Slack} &= \text{Data Required Time} - \text{Data Arrival Time}\\ \text{Data Required Time} &= \text{Latch Edge} + \text{Clock Network Delay to Output Port} - \text{Output Maximum Delay}\\ \text{Data Arrival Time} &= \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Port Delay}\end{aligned}$$

1.2.3. Clock Hold Analysis

To perform a clock hold check, the Timing Analyzer determines a hold relationship for each possible setup relationship that exists for all source and destination register pairs. The Timing Analyzer checks all adjacent clock edges from all setup relationships to determine the hold relationships.

The Timing Analyzer performs two hold checks for each setup relationship. The first hold check determines that the data launched by the current launch edge is not captured by the previous latch edge. The second hold check determines that the data launched by the next launch edge is not captured by the current latch edge. From the possible hold relationships, the Timing Analyzer selects the hold relationship that is the most restrictive. The most restrictive hold relationship is the hold relationship with the smallest difference between the latch and launch edges and determines the minimum allowable delay for the register-to-register path. In the following example, the Timing Analyzer selects hold check A2 as the most restrictive hold relationship of two setup relationships, setup A and setup B, and their respective hold checks.

Figure 11. Setup and Hold Check Relationships

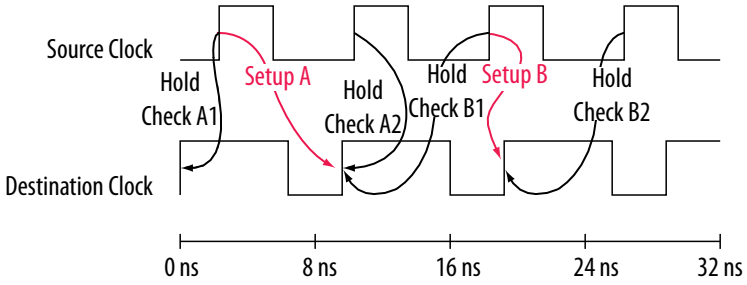


Figure 12. Clock Hold Slack for Internal Register-to-Register Paths

$$\text{Clock Hold Slack} = \text{Data Arrival Time} - \text{Data Required Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_{H} + \text{Hold Uncertainty}$$

The Timing Analyzer performs hold checks using the minimum delay when calculating data arrival time, and maximum delay when calculating data required time.

Figure 13. Clock Hold Slack Calculation from Input Port to Internal Register

$$\text{Clock Hold Slack} = \text{Data Arrival Time} - \text{Data Required Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Minimum Delay} + \text{Pin-to-Register Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_{H}$$

Figure 14. Clock Hold Slack Calculation from Internal Register to Output Port

$$\text{Clock Hold Slack} = \text{Data Arrival Time} - \text{Data Required Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Pin Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay} - \text{Output Minimum Delay}$$

1.2.4. Recovery and Removal Analysis

Recovery time is the minimum length of time for the deassertion of an asynchronous control signal relative to the next clock edge.

For example, signals such as `clear` and `preset` must be stable before the next active clock edge. The recovery slack calculation is similar to the clock setup slack calculation, but the calculation applies to asynchronous control signals.

Figure 15. Recovery Slack Calculation if the Asynchronous Control Signal is Registered

$$\begin{aligned}\text{Recovery Slack Time} &= \text{Data Required Time} - \text{Data Arrival Time}\\ \text{Data Required Time} &= \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU}\\ \text{Data Arrival Time} &= \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}\end{aligned}$$

Figure 16. Recovery Slack Calculation if the Asynchronous Control Signal is not Registered

$$\begin{aligned}\text{Recovery Slack Time} &= \text{Data Required Time} - \text{Data Arrival Time}\\ \text{Data Required Time} &= \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU}\\ \text{Data Arrival Time} &= \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Maximum Delay} + \text{Port-to-Register Delay}\end{aligned}$$

Note: If the asynchronous reset signal is from a device I/O port, you must create an input delay constraint for the asynchronous reset port for the Timing Analyzer to perform recovery analysis on the path.

Removal time is the minimum length of time the deassertion of an asynchronous control signal must be stable after the active clock edge. The Timing Analyzer removal slack calculation is similar to the clock hold slack calculation, but the calculation applies to asynchronous control signals.

Figure 17. Removal Slack Calculation if the Asynchronous Control Signal is Registered

$$\begin{aligned}\text{Removal Slack Time} &= \text{Data Arrival Time} - \text{Data Required Time}\\ \text{Data Arrival Time} &= \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} \text{ of Source Register} + \text{Register-to-Register Delay}\\ \text{Data Required Time} &= \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_{H}\end{aligned}$$

Figure 18. Removal Slack Calculation if the Asynchronous Control Signal is not Registered

$$\begin{aligned}\text{Removal Slack Time} &= \text{Data Arrival Time} - \text{Data Required Time}\\ \text{Data Arrival Time} &= \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Minimum Delay of Pin} + \text{Minimum Pin-to-Register Delay}\\ \text{Data Required Time} &= \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_{H}\end{aligned}$$

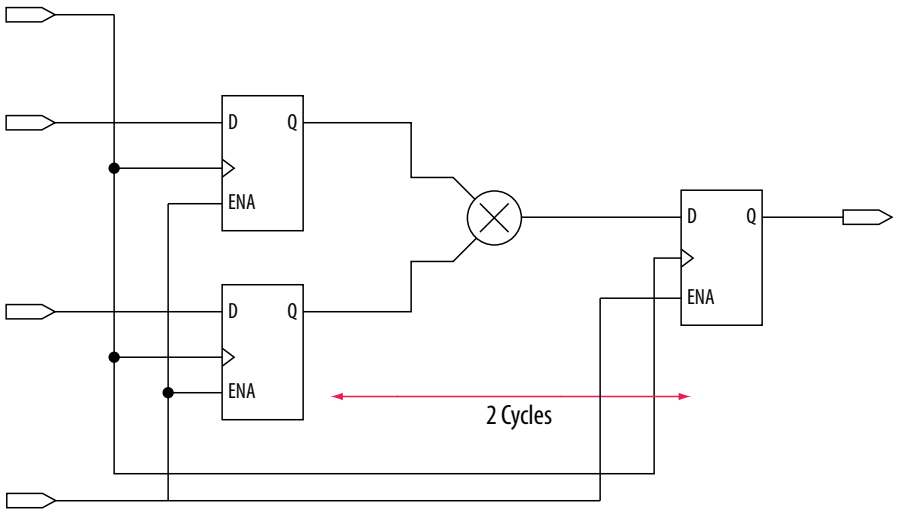
If the asynchronous reset signal is from a device pin, you must create an input delay constraint to the asynchronous reset pin for the Timing Analyzer to perform removal analysis on the path.

1.2.5. Multicycle Path Analysis

Multicycle paths are data paths that require an exception to the default setup or hold relationship, for proper analysis. For example, a register that requires data capture on every second or third rising clock edge (multicycle exception), rather than requiring capture on every clock edge (default analysis).

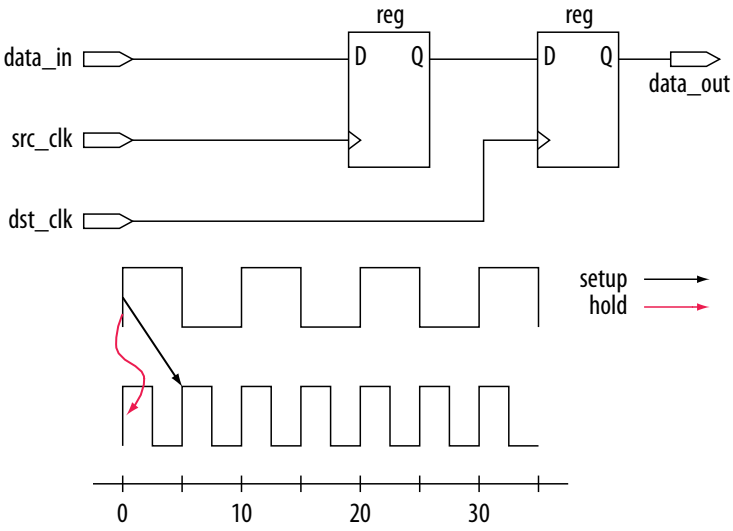
A multicycle path occurs between the input registers of a multiplier, and an output register with a destination that latches data on every other clock edge.

Figure 19. Multicycle Path



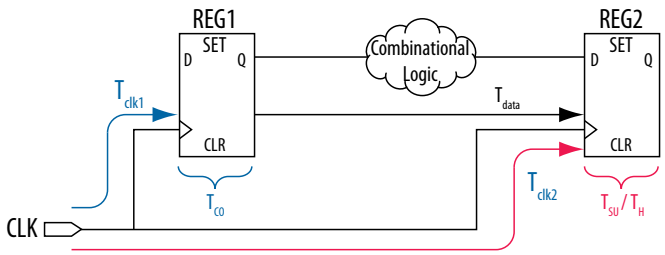
A register-to-register path is for the default setup and hold relationship. Also, for the respective timing diagrams for the source and destination clocks and the default setup and hold relationships, when the source clock, `src_clk`, has a period of 10 ns and the destination clock, `dst_clk`, has a period of 5 ns. The default setup relationship is 5 ns; the default hold relationship is 0 ns.

Figure 20. Register-to-Register Path and Default Setup and Hold Timing Diagram



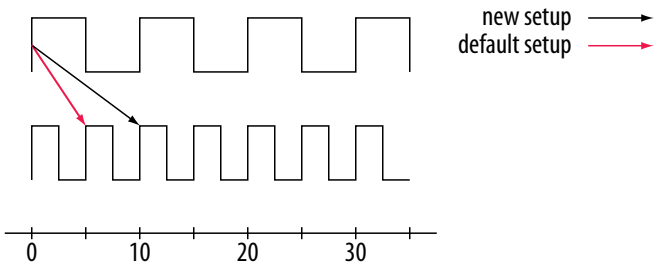
To accommodate the system requirements, you can modify the default setup and hold relationships by specifying a multicycle timing constraint to a register-to-register path.

Figure 21. Register-to-Register Path



The exception has a multicycle setup assignment of two to use the second occurring latch edge; in this example, to 10 ns from the default value of 5 ns.

Figure 22. Modified Setup Diagram



1.2.5.1. Multicycle Clock Hold

The number of clock periods between the clock launch edge and the latch edge defines the setup relationship.

By default, the Timing Analyzer performs a single-cycle path analysis. When analyzing a path, the Timing Analyzer performs two hold checks. The first hold check determines that the data that launches from the current launch edge is not captured by the previous latch edge. The second hold check determines that the data that launches from the next launch edge is not captured by the current latch edge. The Timing Analyzer reports only the most restrictive hold check. The Timing Analyzer calculates the hold check by comparing launch and latch edges.

Figure 23. Hold Check

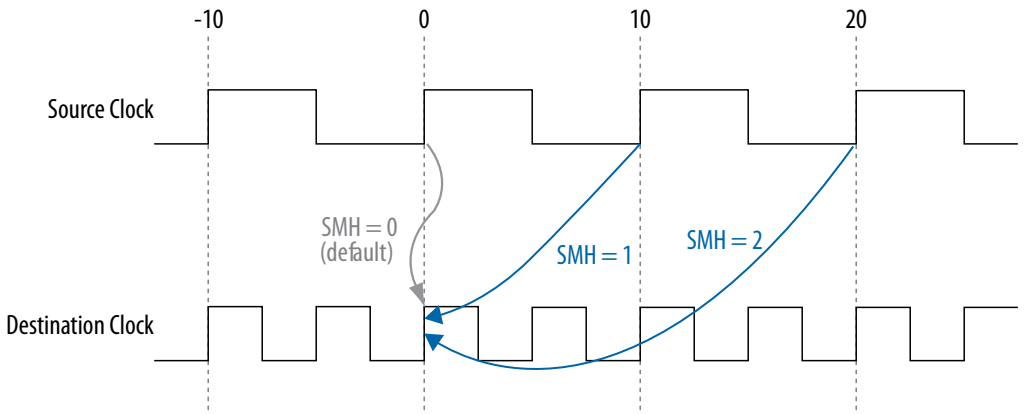
The Timing Analyzer uses the following calculation to determine the hold check.

$$\text{hold check 1} = \text{current launch edge} - \text{previous latch edge}$$
$$\text{hold check 2} = \text{next launch edge} - \text{current latch edge}$$

Tip: If a hold check overlaps a setup check, the hold check is ignored.

A start multicycle hold assignment modifies the launch edge of the source clock by moving the launch edge the number of clock periods you specify to the right of the default launch edge. The following figure shows various values of the start multicycle hold (SMH) assignment and the resulting launch edge.

Figure 24. Start Multicycle Hold Values



An end multicycle hold assignment modifies the latch edge of the destination clock by moving the latch edge the specific number of clock periods to the left of the default latch edge. The following figure shows various values of the end multicycle hold (EMH) assignment and the resulting latch edge.

Figure 25. End Multicycle Hold Values

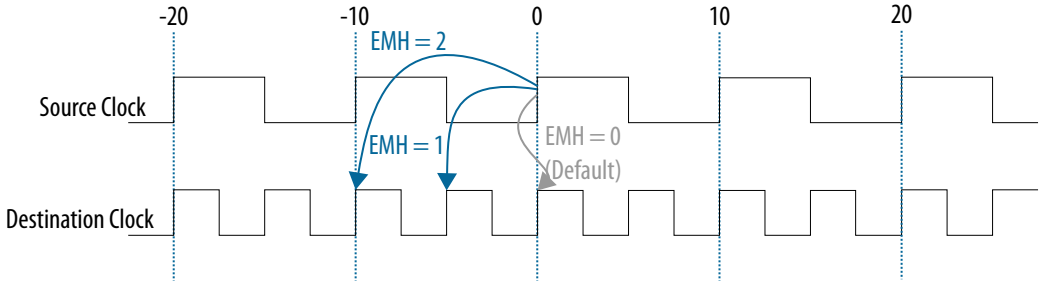


Figure 26. End Multicycle Hold Values the Timing Analyzer Reports

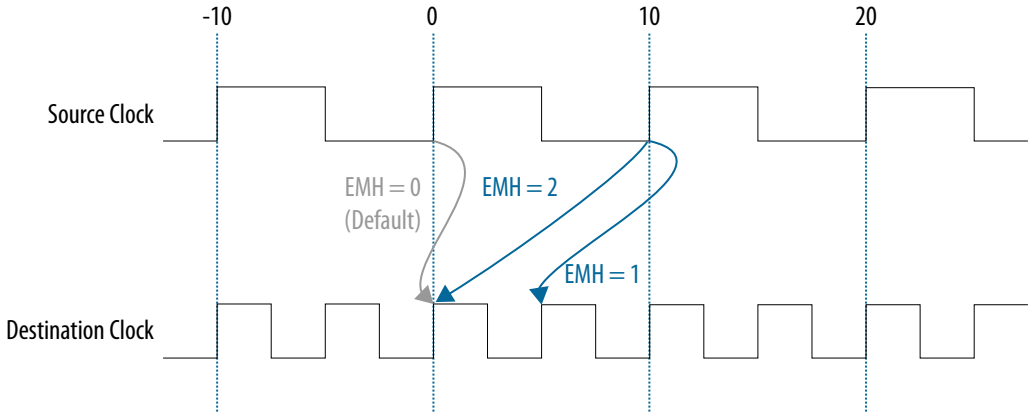
The following shows the hold relationship the Timing Analyzer reports for the negative hold relationship:

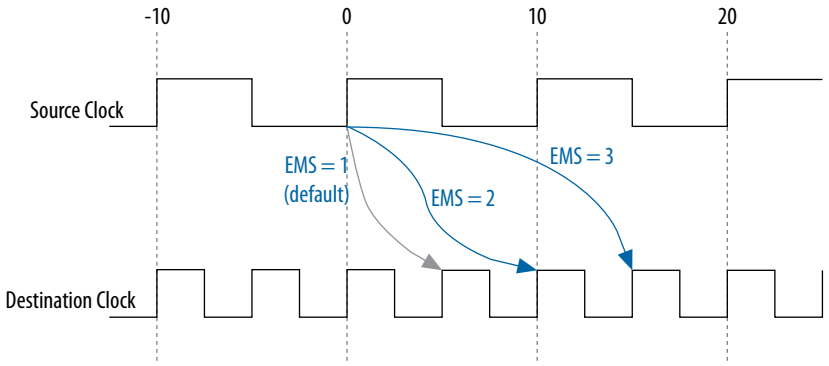


1.2.5.2. Multicycle Clock Setup

The setup relationship is the number of clock periods between the latch edge and the launch edge. By default, the Timing Analyzer performs a single-cycle path analysis, which results in the setup relationship being equal to one clock period (latch edge – launch edge). Applying a multicycle setup assignment, adjusts the setup relationship by the multicycle setup value. The adjustment value may be negative.

An end multicycle setup assignment modifies the latch edge of the destination clock by moving the latch edge the specified number of clock periods to the right of the determined default latch edge. The following figure shows various values of the end multicycle setup (EMS) assignment and the resulting latch edge.

Figure 27. End Multicycle Setup Values



A start multicycle setup assignment modifies the launch edge of the source clock by moving the launch edge the specified number of clock periods to the left of the determined default launch edge. A start multicycle setup (SMS) assignment with various values can result in a specific launch edge.

Figure 28. Start Multicycle Setup Values

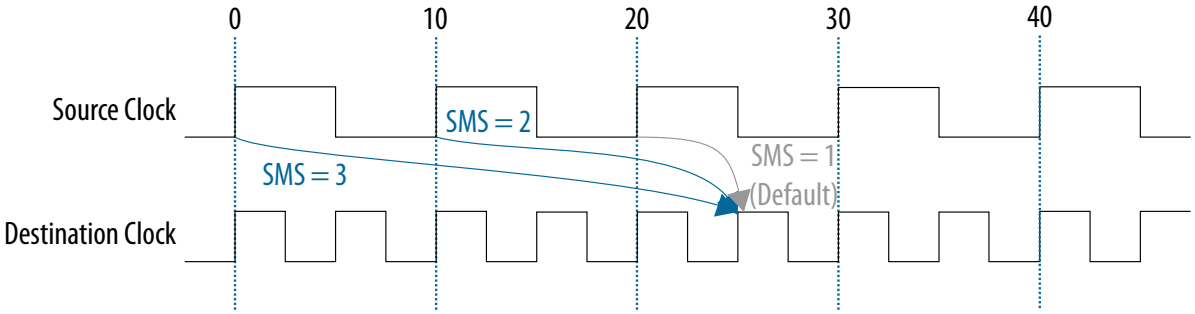


Figure 29. Start Multicycle Setup Values Reported by the Timing Analyzer

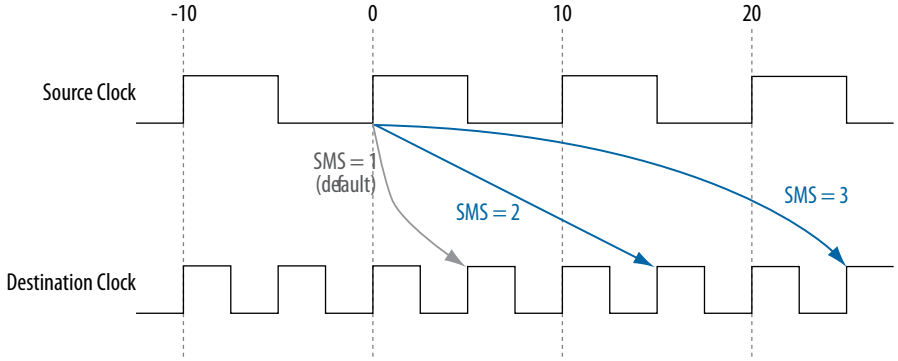
The following shows the negative setup relationship reported by the Timing Analyzer.



1.2.6. Metastability Analysis

Metastability problems can occur when a signal transfers between circuitry in unrelated or asynchronous clock domains because the signal does not meet setup and hold time requirements.

To minimize the failures due to metastability, circuit designers typically use a sequence of registers, also known as a synchronization register chain, or synchronizer, in the destination clock domain to resynchronize the data signals to the new clock domain.

The mean time between failures (MTBF) is an estimate of the average time between instances of failure due to metastability.

The Timing Analyzer analyzes the potential for metastability in your design and can calculate the MTBF for synchronization register chains. The Timing Analyzer then estimates the MTBF of the entire design from the synchronization chains the design contains.

In addition to reporting synchronization register chains found in the design, the Quartus Prime software also protects these registers from optimizations that might negatively impact MTBF, such as register duplication and logic retiming. The Quartus Prime software can also optimize the MTBF of your design if the MTBF is too low.

- report_metastability

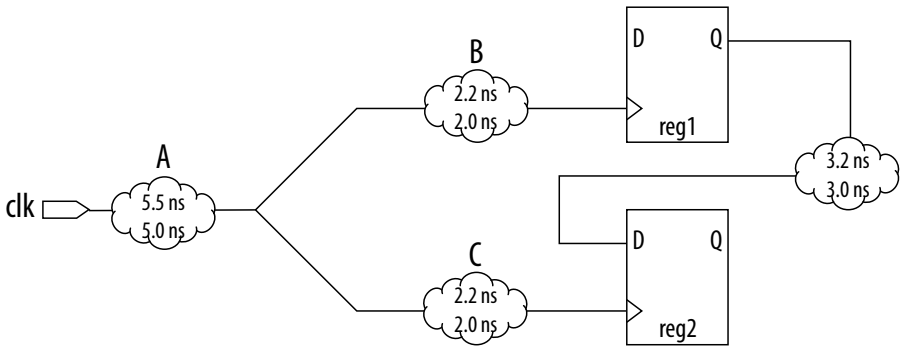
1.2.7. Timing Pessimism

Common clock path pessimism removal accounts for the minimum and maximum delay variation associated with common clock paths during static timing analysis by adding the difference between the maximum and minimum delay value of the common clock path to the appropriate slack equation.

Minimum and maximum delay variation can occur when timing analysis uses two different delay values for the same clock path. For example, in a simple setup analysis, the maximum clock path delay to the source register determines the data

arrival time. The minimum clock path delay to the destination register determines the data required time. However, if the clock path to the source register and to the destination register share a common clock path, both the maximum delay and the minimum delay model the common clock path during timing analysis. The use of both the minimum delay and maximum delay results in an overly pessimistic analysis since two different delay values, the maximum and minimum delays, cannot be used to model the same clock path.

Figure 30. Typical Register to Register Path

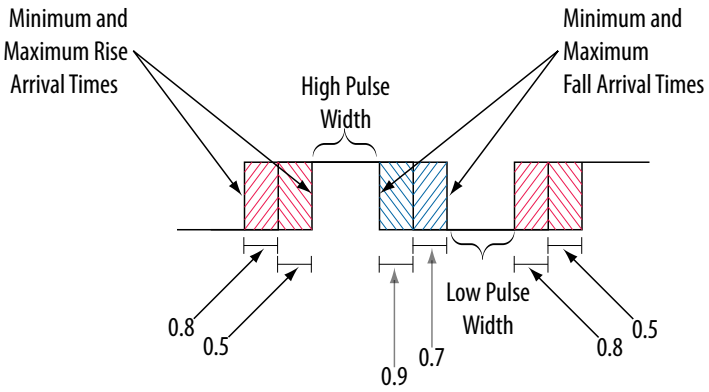


Segment A is the common clock path between `reg1` and `reg2`. The minimum delay is 5.0 ns; the maximum delay is 5.5 ns. The difference between the maximum and minimum delay value equals the common clock path pessimism removal value; in this case, the common clock path pessimism is 0.5 ns. The Timing Analyzer adds the common clock path pessimism removal value to the appropriate slack equation to determine overall slack. Therefore, if the setup slack for the register-to-register path in the example equals 0.7 ns without common clock path pessimism removal, the slack is 1.2 ns with common clock path pessimism removal.

You can also use common clock path pessimism removal to determine the minimum pulse width of a register. A clock signal must meet a register's minimum pulse width requirement for recognition by the register. A minimum high time defines the minimum pulse width for a positive-edge triggered register. A minimum low time defines the minimum pulse width for a negative-edge triggered register.

Clock pulses that violate the minimum pulse width of a register prevent data from latching at the data pin of the register. To calculate the slack of the minimum pulse width, the Timing Analyzer subtracts the required minimum pulse width time from the actual minimum pulse width time. The Timing Analyzer determines the actual minimum pulse width time by the clock requirement you specify for the clock that feeds the clock port of the register. The Timing Analyzer determines the required minimum pulse width time by the maximum rise, minimum rise, maximum fall, and minimum fall times.

Figure 31. Required Minimum Pulse Width time for the High and Low Pulse



With common clock path pessimism, the minimum pulse width slack can increase by the smallest value of either the maximum rise time minus the minimum rise time, or the maximum fall time minus the minimum fall time. In the example, the slack value can increase by 0.2 ns, which is the smallest value between 0.3 ns (0.8 ns – 0.5 ns) and 0.2 ns (0.9 ns – 0.7 ns).

1.2.8. Clock-As-Data Analysis

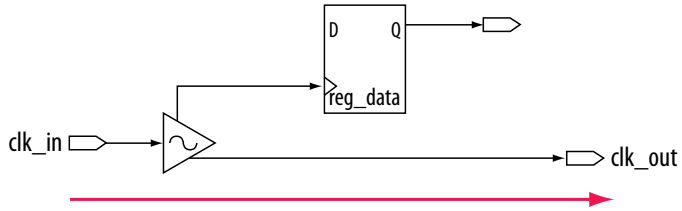
The majority of FPGA designs contain simple connections between any two nodes, known as either a data path or a clock path.

A data path is a connection between the output of a synchronous element to the input of another synchronous element.

A clock is a connection to the clock pin of a synchronous element. However, for more complex FPGA designs, such as designs that use source-synchronous interfaces, this simplified view is no longer sufficient. The Timing Analyzer performs clock-as-data analysis in circuits with elements such as clock dividers and DDR source-synchronous outputs.

You can treat the connection between the input clock port and output clock port as a clock path or a data path. Simplified Source Synchronous Output shows a design where the path from port `clk_in` to port `clk_out` is both a clock and a data path. The clock path is from the port `clk_in` to the register `reg_data` clock pin. The data path is from port `clk_in` to the port `clk_out`.

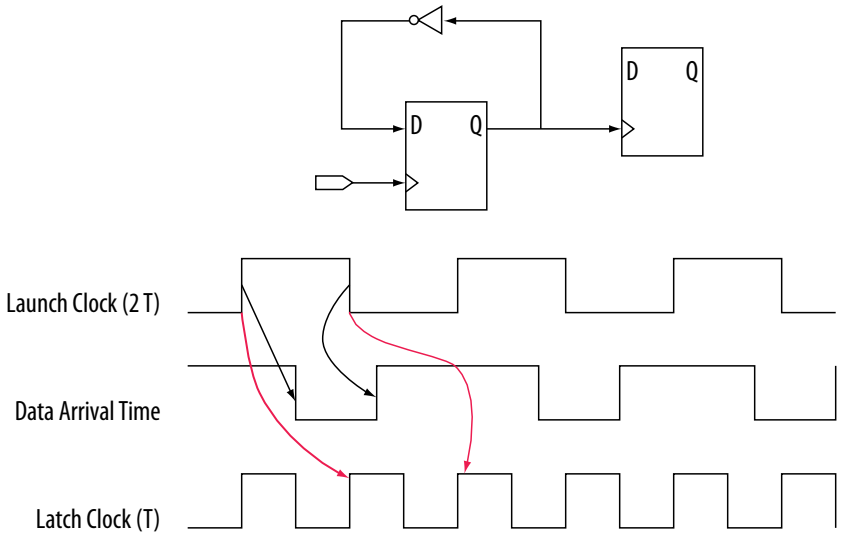
Figure 32. Simplified Source Synchronous Output



With clock-as-data analysis, the Timing Analyzer provides a more accurate analysis of the path based on user constraints. In the clock path analysis, the Timing Analyzer includes any phase shift associated with the phase-locked loop (PLL). For the data path analysis, the Timing Analyzer includes any phase shift associated with the PLL, rather than ignoring the phase shift.

The clock-as-data analysis also applies to internally generated clock dividers. In the following figure, the waveforms are for the inverter feedback path, analyzed during timing analysis. The output of the divider register determines the launch time, and the clock port of the register determines the latch time.

Figure 33. Clock Divider



1.2.9. Multicorner Timing Analysis

You can direct the Timing Analyzer to perform multicorner timing analysis to verify your design under different voltage, process, and temperature operating conditions.

To ensure that no violations occur under different timing conditions (models) during device operation, you must perform static timing analysis under all available operating conditions.

You specify the operating conditions in the Timing Analyzer prior to running analysis.

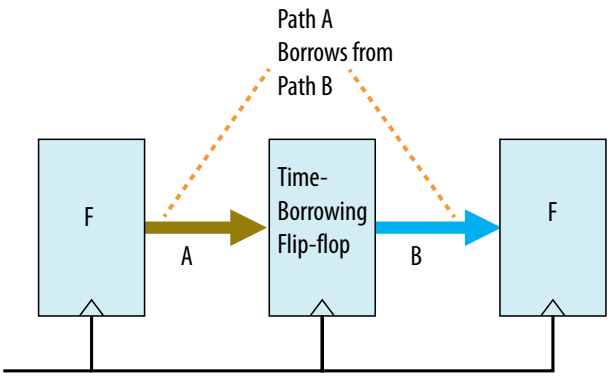
Setting the Operating Conditions for Timing Analysis on page 38

1.2.10. Time Borrowing

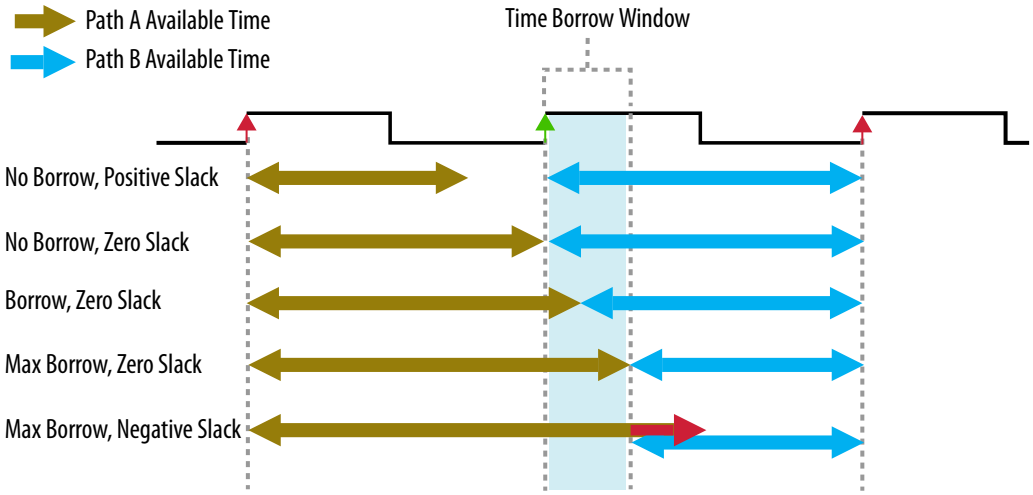
Time borrowing can improve performance by enabling the path ending at a time-borrowing flip-flop or latch to "borrow" time from the next path in the register pipeline. The borrowed time subtracts from the next path, resulting in the same cumulative timing. In this way, time borrowing can shift slack to more critical parts of the design. Without time borrowing, the Timing Analyzer analyzes each path independently and normally assumes exactly one clock cycle for each transfer.

Figure 34. Time Borrowing Example



Some of the flip-flops in Stratix 10 and Arria® 10 devices allow time borrowing. The exact size of the available time borrow window depends on hardware settings. The Fitter (Finalize) stage automatically configures the appropriate borrow window for each time-borrowing flip-flop, based on hardware restrictions and the available hold slack.(1)

Figure 35. Time Borrowing with Various Slack Conditions and Borrow Values



Intel FPGA devices generally support only a few borrow window sizes. For example, Stratix 10 devices support narrow, medium, and wide. Typically, groups of several flip-flops must share the same setting. The actual borrowed amount is completely flexible within a given borrow window. The Timing Analyzer calculates the borrowed amount separately for each operating condition, clock, and signal rise and fall edge. Selecting a wider borrow window reduces hold slack. The Compiler only selects wider settings if hold slack allows. Furthermore, if the Compiler determines that a narrower window is sufficient for a given group of registers (based on the optimal time borrowing solution), the Compiler uses the narrower window, even if there is sufficient hold slack for a wider window.

(1) In Partial Reconfiguration designs, additional restrictions may apply to time-borrowing window size.

For a given borrow window size, the exact size of the borrow window may depend on the register input (for example, `d` or `sclr`), the edge of the incoming signal (rising or falling), the device speed grade, and operating conditions.

You can enable automatic implementation of time borrowing without making any RTL changes. Once enabled, the Fitter automatically configures the window size. The Fitter also determines the optimal time borrow amount within the available borrow window for any design registers that the Fitter places in time-borrowing flip-flops.

Proper timing analysis of designs that contain level-sensitive latches typically requires time borrowing. However, the automatic Fitter time borrowing optimizations do not apply for level-sensitive latches, as Time Borrowing with Latches describes in detail.

Related Information

- Enabling Time Borrowing Optimization on page 23
- Report Time Borrowing Data on page 158

1.2.10.1. Time Borrowing Limitations

Time borrowing optimization, which occurs in the Fitter (Finalize) stage, cannot occur for the following registers. For these registers, the time borrowing optimization is zero, and the maximum operating frequency in the **Fmax Summary** reports include zero time borrowing:

- Any register that is the source of a cross-clock transfer
- Any register that is the source of a `set_max_skew` or `set_max_delay` assignment
- Any register in a clock domain with one or more level-sensitive latch

Furthermore, registers that are destinations of cross-clock transfers, `set_max_skew` or `set_max_delay` constraints do not have borrowing values that are optimized for such transfers (but may still have non-zero borrowing from other transfers).

If any such registers are on the critical timing path, you can possibly report better performance by enabling Dynamic time borrowing mode, which reports time borrowing for all borrow-capable registers. Dynamic time borrowing mode can then provide a more accurate (less pessimistic) analysis, but only at a specific set of clock frequencies that you specify in the `.sdc`.

To view time borrowing results for such registers:

1. Set the clock frequency in the `.sdc` file to a value higher than the clock frequency that **Fmax Summary** reports.
2. Reset your design and read the SDC file again in the Timing Analyzer.
3. Run the `update_timing_netlist -dynamic_borrow` command.
4. View the results in **Slack Summary** reports (**Reports ➤ Slack** to determine if timing passes. The **Fmax Summary** report does not reflect any gains from dynamic borrowing.

Note: Time borrowing is similar to the beneficial clock skew technique, whereby you delay the clock to a given register, giving more time to the incoming paths at the expense of the outgoing paths. However, time borrowing and beneficial clock skew have the following important differences:

- Time borrowing offers more flexibility than clock skew in distributing setup slack. Skewing is typically limited to fixed increments. You can use borrowing to shift any amount of slack (however small) from one side of the register to the other, as long as the amounts fit within the available borrow window. Furthermore, borrow amounts calculate separately for each operating condition, making it possible to shift the optimum amount of slack for each operating condition. This type of shifting is not possible with skewing.
- You can use beneficial clock skew to increase Hold slack on outgoing paths from the register where the clock is skewed. Time borrowing does not offer this benefit.

1.2.10.2. Time Borrowing with Latches

The Quartus Prime Timing Analyzer treats level-sensitive latches similar to registers. The Timing Analyzer treats the latch enable pin as a clock pin, while modifying the clock relationship appropriately.

You can run **Reports ➤ Constraint Diagnostics ➤ Check Timing** in the Timing Analyzer **Tasks** pane to view a list of the level-sensitive latches in your design.

Implementation of latch time borrowing requires that you enable Dynamic borrowing mode (`update_timing_netlist -dynamic_borrow`). Otherwise, the Timing Analyzer calculates zero time borrowing for latches. In Dynamic mode, the Timing Analyzer simply reports the amount of time borrowing that would physically happen in the circuit, given the clock frequencies you specify in SDC constraints, and does not actually optimize borrowing in any way.

For latches, the setup relationship is to the opening edge of the latch, which allows time borrowing. The hold relationship is to the closing edge of the latch. For example, a path from a positive register to another positive register has a default setup clock relationship of one clock period. A path from a positive register to a positive (open-high), level-sensitive latch has a default setup clock relationship of zero clock periods, plus any time borrow value.

The Timing Analyzer treats paths to and from a latch as two separate paths. For example, in a positive register--> positive latch--> negative register transfer, the Timing Analyzer does not analyze the overall register-->register transfer, even though you expect the latch to be transparent for the entire duration of the transfer. The Timing Analyzer analyzes and reports the paths to and from the latch separately.

The Timing Analyzer automatically computes the maximum amount of time borrowing available for each latch. Typically, the maximum amount of time borrowing available is roughly equivalent to half the clock period. The exact amount of time borrowing available is based on:

- The timing of opening and closing latch edges
- Physical latch implementation (closing-edge μt_{SU} of the latch)
- Clock uncertainty and other effects

The time borrowing never exceeds the maximum borrow value. However, you can specify a smaller maximum borrow time with the `set_max_time_borrow` SDC constraint. For example:

```
#Borrow at most 3ns at all "lat*" latches:
set_max_time_borrow 3 [get_registers lat*]
```

Specifying a clock with a negative borrow window can result in negative maximum borrowable time, which is equivalent to a minimum pulse width violation. For example, this condition can occur if half the clock period is smaller than the closing-edge μt_{SU} of the latch. If such a violation occurs, a warning indicates that the design cannot pass timing.

Note: Whether you use time borrowing or not, do not rely on the timing analysis **Fmax Summary** report for any clock domains with latches. The **Fmax Summary** values for such clock domains include no borrowing, and are therefore significantly pessimistic.

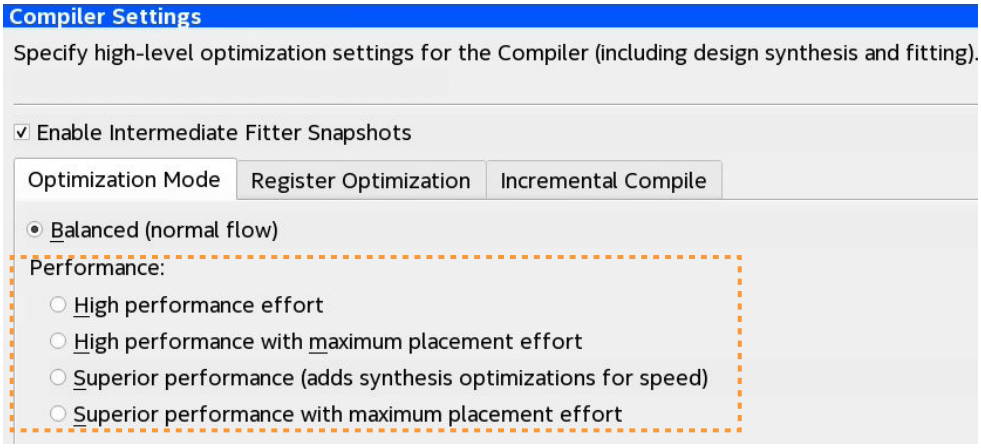
1.2.10.3. Enabling Time Borrowing Optimization

During any High or Superior **Performance** compilation, the Compiler automatically computes and stores **Optimal** time borrow values for Stratix 10 and Arria 10 designs during the Finalize stage. By default, the subsequent timing analysis results reflect the **Optimal** borrow values from the Finalize stage.

Follow these steps to enable time borrowing for supported devices:

1. Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Optimization Mode**. Select any high or superior **Performance** setting.
2. Run the Fitter and Timing Analyzer, as Step 3: Run the Timing Analyzer on page 34 describes.
3. To generate reports showing time borrowing data, click **Reports ➤ Timing Slack ➤ Report Timing**. Time borrowing data appears on the critical path for a given clock domain, as Report Time Borrowing Data describes.

Figure 36. Performance Compiler Optimization Mode Settings



- To specify time borrowing optimization without changing the Compiler **Optimization Mode**, specify the following assignment in the project `.qsf`:

```
set_global_assignment -name ENABLE_TIME_BORROWING_OPTIMIZATION <ON|OFF>
```

- To manually specify the time borrow mode during timing analysis, run one of the following `update_timing_netlist` command options:

Table 2. Time Borrowing Modes

Time Borrowing Mode	Command Option	Default Mode For
Optimal—timing analysis includes optimal time borrow values from the Finalize stage. You can optionally add the `recompute_borrow` option to `update_timing_netlist` to recompute the borrow amounts, but not the borrow window sizes.	`update_timing_netlist`	High and Superior performance compilations for Stratix 10 and Arria 10 designs.
Dynamic—timing analysis reports the time borrowing that would physically occur on the device, with respect to your SDC constraints, without any optimization. That is, timing analysis applies as much borrowing as necessary to fix all negative slack. Timing analysis assumes maximum possible borrowing for any timing path where the maximum amount of time borrowing is insufficient to eliminate all negative slack. Only mode that allows borrowing for level-sensitive latches.	`update_timing_netlist -dynamic_borrow` `update_timing_netlist -loop_aware_dynamic_borrow`	None
Zero—timing analysis uses zero time borrowing.	`update_timing_netlist –no_borrow`	Unsupported devices, or any Compiler Optimization mode other than a **Performance** mode.

Note: Dynamic mode cannot yield the optimal results with overconstrained clocks, as overconstrained clocks result in excessive negative slack on almost every path. This condition causes use of maximum time borrowing everywhere, which is unlikely to be optimal. When using Partial Reconfiguration, if you compile the base design with time borrowing enabled, compile the implementation design(s) with time borrowing enabled. Otherwise, time borrowing amounts in the base design reset to zero, and the design may not pass timing. If this condition occurs, you can use the `update_timing_netlist –recompute_borrow` command to restore time borrowing amounts throughout the design.

1.3. Timing Analysis Overview Document Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Updated *What's New In This Version* topic for DNI, SDC-on-RTL, and locating from report to source file.
2023.04.03	23.1	• Updated *What's New In This Version* topic for changes to entity-bound SDCs.
2022.03.28	22.1	• Added Top FAQ navigation to cover page. • Added new *What's New In This Version* topic for changes to Report Register Statistics report.
2020.09.28	20.3	• Revised setup arrow direction in multiple timing diagrams for consistency.
2020.04.13	20.1	• Added "Time Borrowing" section.
2019.09.30	19.3	• Updated "MultiCorner Timing Analysis" code example and stated limitation for operating conditions.
2019.07.15	19.2	• Updated "MultiCorner Analysis" for SmartVID timing models.
2018.09.24	18.1	Minor text enhancements for clarity and style.

Table 3. Document Revision History

Date	Version	Changes
2016.10.31	16.1	• Implemented Intel rebranding.
2016.05.02	16.0	Corrected typo in Fig 6-14: Clock Hold Slack Calculation from Internal Register to Output Port
2015.11.02	15.1	Changed instances of *Quartus II* to *Quartus Prime*.
2014.12.15	14.1	Moved Multicycle Clock Setup Check and Hold Check Analysis section from the Timing Analyzer chapter.
June 2014	14.0	Updated format
June 2012	12.0	Added social networking icons, minor text updates
November 2011	11.1	Initial release.

2. Using the Quartus Prime Timing Analyzer

The Quartus Prime Timing Analyzer is a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology. Use the Timing Analyzer GUI or command-line interface to constrain, analyze, and report results for all timing paths in your design.

Figure 37. Quartus Prime Timing Analyzer GUI

2.1. Using Timing Constraints throughout the Design Flow

To ensure accurate timing analysis, it is essential to define proper timing constraints that specify your design's clock frequency requirements, timing exceptions, and I/O timing specifications for comparison with actual conditions.

You specify the timing constraints in various Synopsys Design Constraint (SDC) files that you add to the project. You can define SDC files and run timing analysis at two key stages of the design compilation flow:

- After running **Analysis & Synthesis**—you can run Early Timing Analysis based on the synthesized design and initial SDC-on-RTL constraints you specify. If you're starting a new design, you can use SDC-on-RTL constraint methodology to learn benefits of timing analysis after synthesis. If you've already partially completed an existing design, it is best to use conventional SDC constraints.
- After running the **Fitter**—you can run post-fit timing analysis that accounts for actual path delays and the conventional SDC constraints you specify.

Post-Synthesis Early Timing Analysis Constraints

After running **Analysis & Synthesis**, you can run post-synthesis Early Timing Analysis based on the synthesized design and initial constraints that you define with SDC-on-RTL (`.rtlsdc`) or a synthesis-only conventional (`.sdc`). SDC-on-RTL allows you to define constraints using the same names in your design RTL, ensuring that your timing constraints names align closely with the RTL node names in the elaborated netlist.

Early timing analysis uses the initial SDC-on-RTL constraints that you specify to perform post-synthesis static timing analysis without needing to run the Fitter. The Compiler reads the constraints during Analysis & Elaboration, and then applies the SDC-on-RTL constraints for all downstream stages of compilation. For more details, refer to Specifying SDC-on-RTL Timing Constraints for step by step instructions.

As an alternative to SDC-on-RTL, you can define a conventional synthesis-only `.sdc` that applies the constraints only for design synthesis, as Specifying Synthesis-Only SDC Timing Constraints describes.

Post-Fit Timing Analysis Constraints

After running the Fitter's Plan, Place Route, Fitter (Finalize) stage, you can run post-fit timing analysis that accounts for actual path delays based on the Planned, Placed, or Routed design with constraints that you define in conventional SDC (`.sdc`) files. This post-fit timing analysis provides the most precise control over timing constraints.

You can define a conventional `.sdc` file directly in the Timing Analyzer GUI, or use the SDC file templates available using **Edit ➤ Insert Template**. You can alternatively define an `.sdc` file in any text editor and then integrate it into your project. Refer to Specifying Conventional SDC Timing Constraints.

The SDC File Types Supported table summarizes the differences between the various SDC file types and when the Quartus Prime software uses them.

Table 4. Supported SDC File Types

	SDC-on-RTL	Synthesis-Only SDC	Conventional SDC
Stage where constraints are read	Analysis & Elaboration	Synthesis	Fitter, Signoff
Stage where constraints are processed	Synthesis through Fitter	Synthesis only	Fitter, Signoff
QSF assignment	`RTL_SDC_FILE` (supports entities)	`SDC_FILE SDC_ENTITY_FILE -read_during_post_syn_and_post_fit_timing_analysis`	`SDC_FILE`
		`SDC_FILE SDC_ENTITY_FIL E -read_during_post_syn_and_not_post_fit_timing_analysis`	
Syntax supported	Tcl with SDC 2.1 commands	Tcl with Quartus Prime SDC commands	Tcl with Quartus Prime SDC commands
SDC 2.1-compliant	Yes	No	No
Target type	RTL	Quartus Prime timing graph	Quartus Prime timing graph
Hierarchical targets	Yes	No	No
Buried timing nodes (used by IP)	No	Core fabric only. Such nodes do not exist for the periphery in post-synthesis timing analysis.	Yes
STA command to load constraints	Executes the `read_sdc` or `import_sdc` command in any snapshot.	Executes the `read_sdc` command only during static timing analysis on the synthesized snapshot.	Executes the `read_sdc` command during static timing analysis on any fitter snapshot (plan, place, route, retime). Not loaded during synthesis.

2.2. Timing Analysis Flow

The following describes high-level steps in the timing analysis flow. This section describes each step in detail:

- Step 1: Specify General Timing Analyzer Settings on page 29
- Step 2: Specify Timing Constraints on page 30
- Step 3: Run the Timing Analyzer on page 34
- Step 4: Analyze Timing Reports on page 40

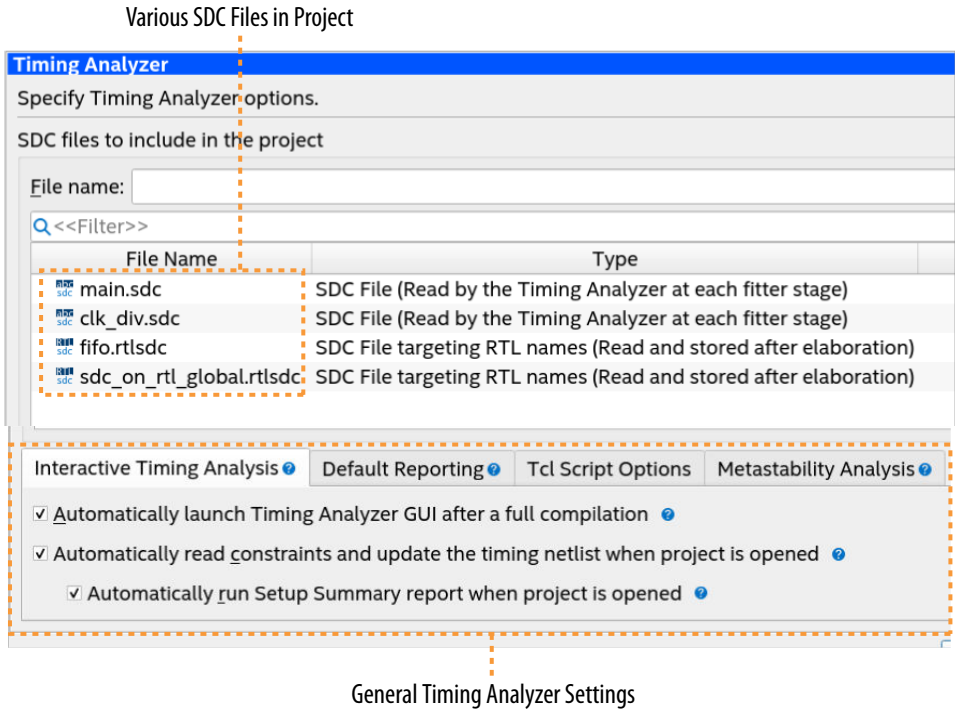
2.2.1. Step 1: Specify General Timing Analyzer Settings

Before running timing analysis, you must open an Quartus Prime project. You can then consider and specify general settings for timing analysis, as well as other project-wide Compiler settings that impact the timing analysis results.

To specify general Timing Analyzer settings, follow these steps:

1. To open an existing project, click **File ➤ Open Project**.
2. Click **Assignments ➤ Settings ➤ Timing Analyzer** to open the **Timing Analyzer** settings.

Figure 38. Timing Analyzer Page of Settings Dialog Box



3. In the **Timing Analyzer** page, specify one or more of the following general Timing Analyzer general settings:

Table 5. Timing Analyzer General Settings

Setting	Description
SDC files to include in the project	Specifies the name and processing order of timing constraint files in the project, such as conventional .sdc files and SDC-on-RTL (`.rtlsdc`) files. For more details, refer to Using Timing Constraints Effectively and Step 2: Specify Timing Constraints.
Interactive Timing Analysis	Specify options for automatically running timing analysis, reading constraints, and generating reports automatically. Turn on or off:

continued...

Setting	Description
	• **Automatically launch Timing Analyzer GUI after a full compilation** (default, on) • **Automatically read constraints and update the timing netlist when project is opened** in Timing Analyzer (default, on) • **Automatically run setup summary report when project is opened** in Timing Analyzer (default, on)
Default Reporting	Specify options to automatically **Report worst-case paths during compilation** (default, on). Specify the **Paths reported per clock domain** (default, 10), and whether to **Show routing** (default, off) in reports.
Tcl Script Options	**Tcl Script File name** specifies the file name for a custom timing analysis script. You can specify whether to **Run default timing analysis before running custom script**.
Metastability Analysis	Specifies how the Timing Analyzer identifies registers as being part of a synchronization register chain for metastability analysis.

4. Consider and specify project-wide Compiler settings that impact timing analysis:

Table 6. Compiler Settings Impacting Timing Analysis

Setting	Description	Location
Enable multicorner support for Timing Analyzer and EDA Netlist Writer(default, on)	Directs the Timing Analyzer to perform multicorner timing analysis by default, which analyzes the design against best-case and worst-case operating conditions.	**Assignments ➤ Settings ➤ Compilation Process Settings**
Optimization Mode (default, Balanced)	Specifies the focus of Compiler optimization efforts during synthesis and fitting. Specify a **Balanced** strategy, or optimize for **Performance**, **Area**, **Power**, **Routability**, or **Compile Time**.	**Assignments ➤ Settings ➤ Compiler Settings**
SDC Constraint Protection (default, off)	Verifies `.sdc` constraints in register merging. This option helps to maintain the validity of `.sdc` constraints through compilation.	**Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)**
Synchronization Register Chain Length (default, 3)	Specifies the maximum number of registers in a row that the Compiler considers as a synchronization chain. The Compiler considers these registers for metastability analysis. The Compiler prevents optimizations of these registers, such as retiming. When gate-level retiming is enabled, the Compiler does not remove these registers.	**Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)**
Optimize Design for Metastability (default, on)	This setting improves the reliability of the design by increasing its Mean Time Between Failures (MTBF). The Fitter increases the output setup slacks of synchronizer registers in the design. This slack can exponentially increase the design MTBF. This option only applies when using the Timing Analyzer for timing-driven compilation. Use the Timing Analyzer `report_metastability` command to review the synchronizers detected in your design and to produce MTBF estimates.	**Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**

2.2.2. Step 2: Specify Timing Constraints

You can use any combination of the following to enter the timing constraints for your Quartus Prime project throughout the design flow, as Using Timing Constraints Effectively throughout the Design Flow describes.

- Specifying SDC-on-RTL Timing Constraints
- Specifying Conventional SDC Timing Constraints
- Specifying Synthesis-Only SDC Timing Constraints

2.2.2.1. Specifying SDC-on-RTL Timing Constraints

To specify SDC-on-RTL timing constraints for post-synthesis Early Timing Analysis, follow these steps:

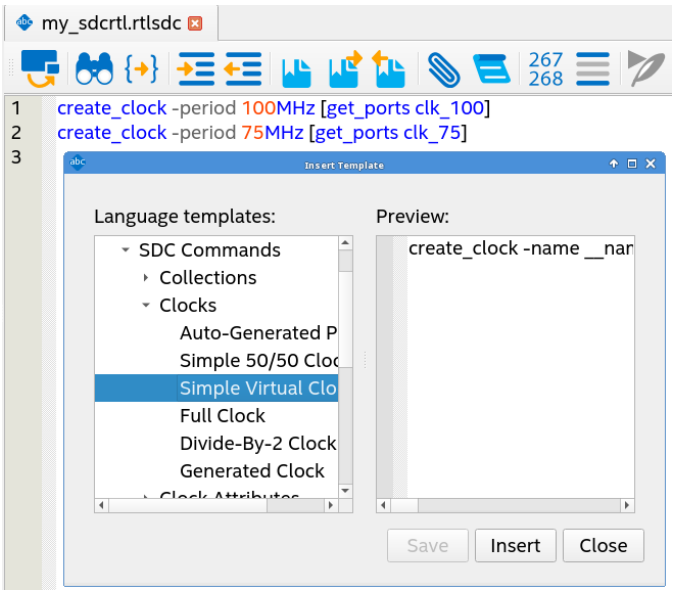
1. In the Quartus Prime software, click **File ➤ New** and then select the **SDC File Targeting RTL Names** (`.rtlsdc`) file type. The new file opens in the Text Editor.

   You can specify any extension for SDC-on-RTL constraints, but this document always uses the file extension `.rtlsdc` to distinguish from conventional SDC files.

2. In the Text Editor, define SDC-on-RTL constraints. You can click **Edit ➤ Insert Template ➤ Timing Analyzer** to insert available SDC templates. Alternatively, use any other text editor to enter the constraints and save as `.rtlsdc` file type.

   Note: SDC-on-RTL constraints support a subset of conventional SDC commands. The syntax and arguments of SDC-on-RTL constraints aligns with the SDC 2.1 standard. The Quartus Prime software may support more than just the SDC 2. 1 commands because of some Quartus Prime software-specific arguements.

Figure 39. Inserting SDC Templates



Note: The `-comment` argument in SDC-on-RTL allows you to add a constraint comment. This comment does not appear in timing analysis reports.

3. Save the `.rtlsdc` file in the Quartus Prime Text Editor, turning on the **Add File to Project** option.

Note: You can add any SDC file to the project at any time by clicking **Assignments ➤ Settings ➤ Timing Analyzer**.

4. Run post-synthesis Early Timing Analysis, as Running Post-Synthesis Early Timing Analysis describes.

   Note: As an alternative to SDC-on-RTL constraints, you can consider initially specifying synthesis-only constraints that apply only to the Analysis & Synthesis stage of compilation, as Specifying Synthesis-Only SDC Timing Constraints describes.

Related Information

- Using Entity-Based SDC-on-RTL Constraints on page 57
- Automatic Scope Example for SDC-on-RTL on page 61
- Manual Scope Example for SDC-on-RTL on page 64
- Using Synopsys* Design Constraint (SDC) on RTL Files

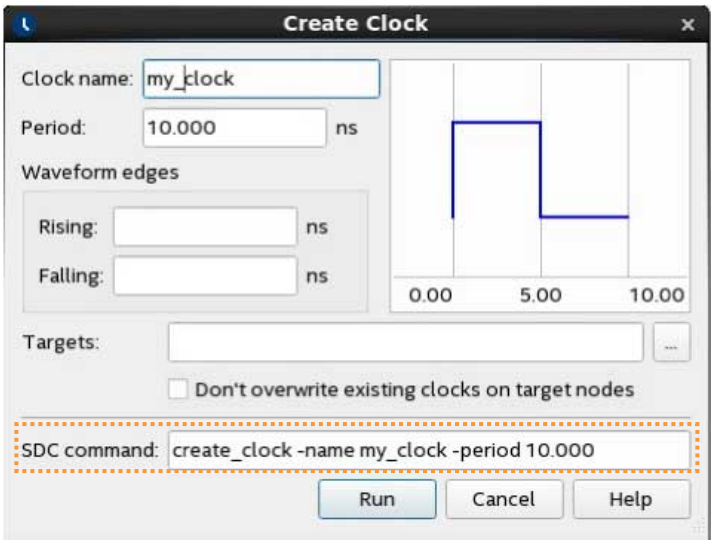
2.2.2.2. Specifying Conventional SDC Timing Constraints

To specify conventional timing constraints for post-fit timing analysis in the Timing Analyzer GUI, follow these steps:

Note: As an alternative to the Timing Analyzer GUI, you can specify conventional SDC constraints directly in a `.sdc` text file and add it to the project.

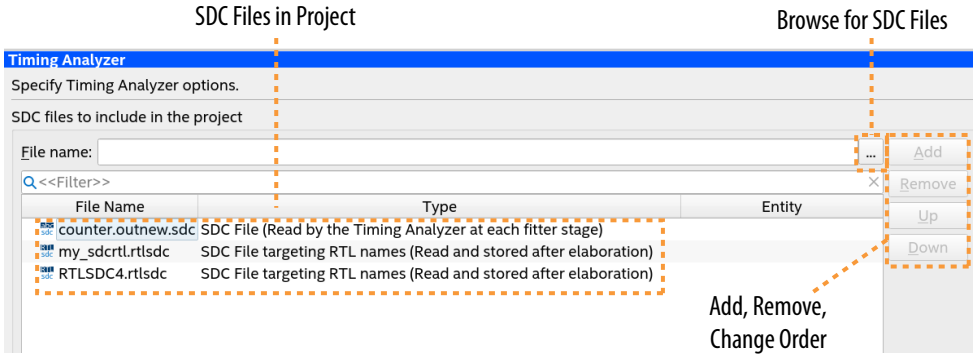
1. In the Timing Analyzer GUI, click the **Constraints** menu and then click the constraint that you want to define. You can start by adding the Recommended Initial Conventional SDC Constraints, and then iteratively modify the constraints and reanalyze the timing results.
2. In the GUI, specify values for the constraint and click **OK**. The **SDC command** field echoes the corresponding SDC command that applies as you enter the constraint value in the GUI.

Figure 40. Create Clock Dialog Defines Clock Constraints



3. When done entering constraints, click **Constraints ➤ Write SDC File** to save the constraints to an .sdc file.
4. To add the conventional .sdc file to your project, click **Assignments ➤ Settings ➤ Timing Analyzer**.

Figure 41. Adding an SDC to the Project



5. Run post-fit timing analysis, as Running Post-Fit Timing Analysis describes.

Related Information

- Using Entity-Bound SDC Files on page 64
- Automatic Scope Entity-bound Constraint Example on page 69
- Manual Scope Entity-bound Constraint Example on page 71

2.2.2.3. Specifying Synthesis-Only SDC Timing Constraints

You use this synthesis-only SDCs if you want to create custom SDC's that apply just for post-synthesis timing analysis, but you do not want the constraints to apply to other downstream stages of the compilation flow. If you want the constraints to persist post-synthesis, you can use SDC-on-RTL constraints, as Specifying SDC-on-RTL Timing Constraints describes.
Follow these steps to define a conventional `.sdc` file that applies only to the Analysis & Synthesis stage of compilation.

1. Create a conventional `.sdc` file that contains only the timing constraints for the Analysis & Synthesis stage of compilation, as Specifying Conventional SDC Timing Constraints describes.
2. To apply the conventional `.sdc` to the project for synthesis-only, add the following assignment to the project:

```
set_global_assignment -name SDC_ENTITY_FILE <file>.sdc /
   -entity <name> -read_during_post_syn_and_not_post_fit_timing_analysis
```

3. To run design synthesis and apply the constraints to the timing netlist, click **Analysis & Synthesis** on the Compilation Dashboard.
4. Click the **Open Timing Analyzer** icon next to **Analysis & Synthesis** on the Compilation Dashboard. The synthesis-only constraints now apply to only the static timing analysis of this synthesized snapshot.
5. Analyze the results of Early Timing Analysis, as Step 4: Analyze Timing Reports on page 40 describes.

2.2.3. Step 3: Run the Timing Analyzer

The Timing Analyzer generates reports that you can review to determine the performance of your design compared against your timing constraints. You can run timing analysis at two key stages of the design compilation flow:

- After running **Analysis & Synthesis**—you can run Early Timing Analysis based on the synthesized design and initial SDC-on-RTL constraints you specify.
- After running the **Fitter**—you can run post-fit timing analysis that accounts for actual path delays and the conventional SDC constraints you specify.

2.2.3.1. Running Post-Synthesis Early Timing Analysis

Running the Early Timing Analysis stage of compilation provides a preliminary view of your design's core timing. Before running Early Timing Analysis, you must setup your design RTL, the Quartus Prime project, specify timing constraints, and run the Compiler through the Analysis & Synthesis stage.

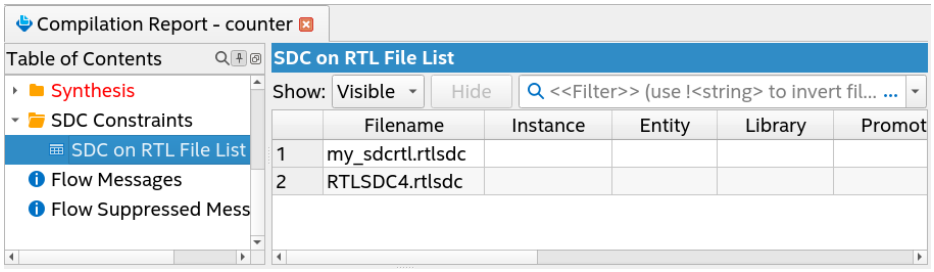
To run post-synthesis Early Timing Analysis, follow these steps:

1. Specify SDC-on-RTL timing constraints for Early Timing Analysis, as Specifying SDC-on-RTL Timing Constraints describes.

Note: As an alternative to SDC-on-RTL, you can define a synthesis-only `.sdc`, as Specifying Synthesis-Only SDC Timing Constraints describes.

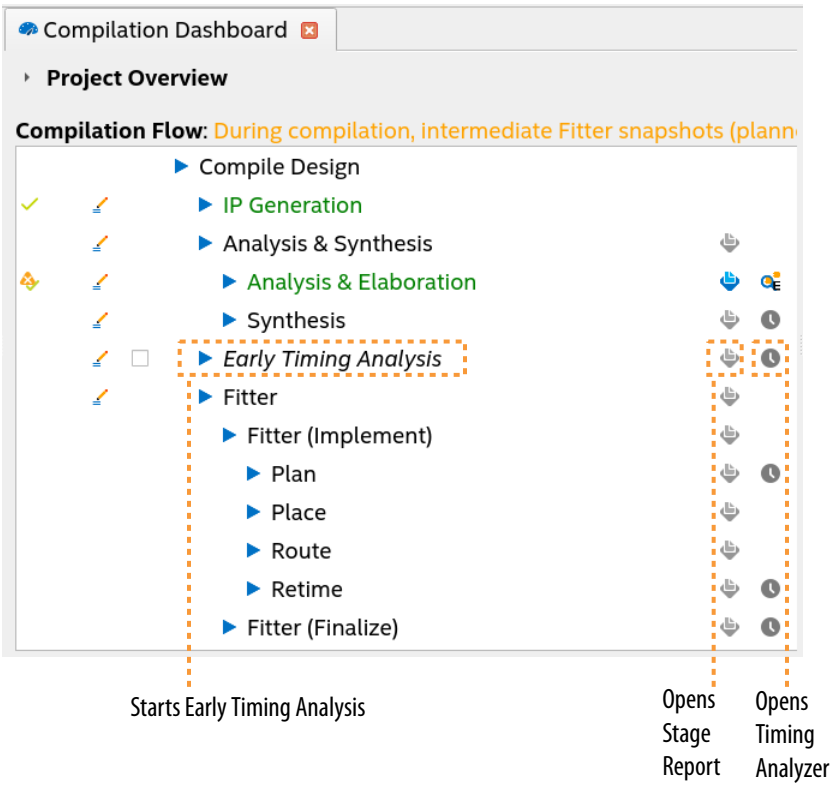
2. On the Compilation Dashboard, click **Analysis & Elaboration**. Analysis & Elaboration processes all SDC-on-RTL, applying the constraints to the design netlist. During Analysis & Elaboration, messages confirm that the Compiler appropriately applies each `.rtlsdc` file according to its assigned module.
3. To review the implementation of constraints when Elaboration & Analysis completes, click the **Open Compilation Reports** icon next to **Elaboration & Analysis** in the Compilation Dashboard.
4. Click the **SDC Constraints ➤ SDC-on-RTL File List** report to view all SDC-on-RTL files in the current project.

Figure 42. SDC-on-RTL File List Report



5. Click **Analysis & Synthesis** on the Compilation Dashboard. Analysis & Synthesis transforms the elaborated netlist into a node netlist for device resource mapping and generates a simplified device delay model that excludes precise Fitter-generated timing delays. This simplified delay model provides an early overview of the design delays based on block types that connect to a net. Analysis & Synthesis propagates SDC-on-RTL constraints to subsequent compilation stages, thereby applying to all subsequent Timing Analyzer runs.
6. To run Early Timing Analysis and view the results, double-click **Early Timing Analysis** on the Compilation Dashboard. The Compiler runs Analysis & Synthesis and then initializes the Timing Analyzer.

Figure 43. Running Early Timing Analysis from Compilation Dashboard



7. When Analysis & Synthesis completes, click the **Open Timing Analyzer** icon next to **Early Timing Analysis** on the Compilation Dashboard. The Timing Analyzer opens with the updated timing netlist loaded automatically.
8. In the Timing Analyzer reports, view the preliminary timing report data measured against your SDC-on-RTL constraints, such as the **Setup Summary**, **Create Generated Clocks**, and **Set False Path** reports. Refer to Step 4: Analyze Timing Reports.

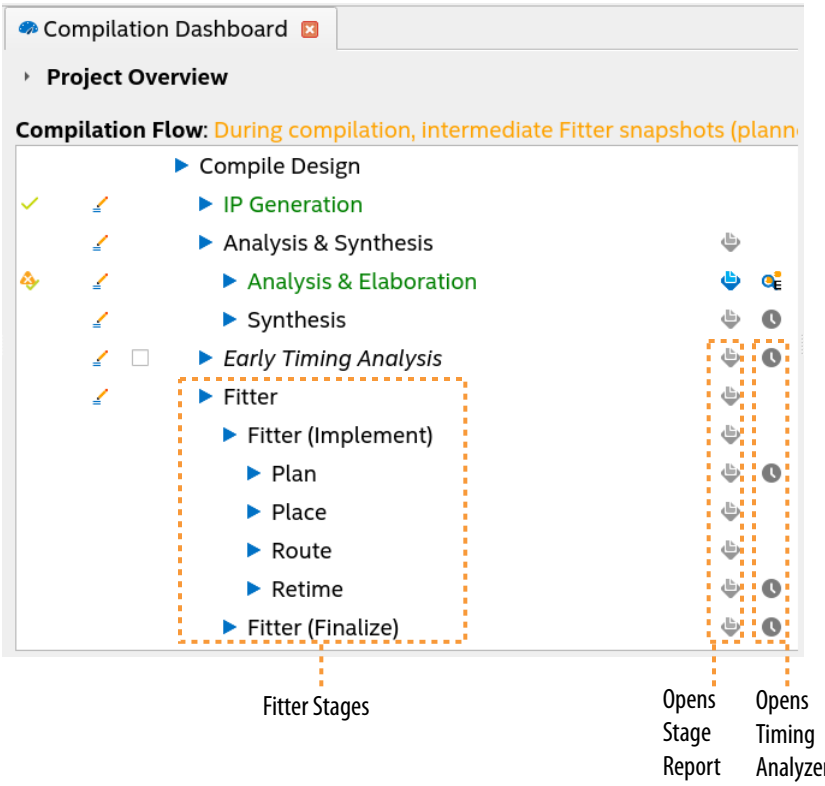
2.2.3.2. Running Post-Fit Timing Analysis

Before running post-fit timing analysis, you must run the Fitter to apply conventional SDC constraints to the post-fit timing netlist. The Fitter then attempts to place the logic of your design to adhere to the timing constraints you specify. After running the Fitter, the Timing Analyzer generates reports detailing the margin (slack) by which your design either meets or fails each constraint. The post-fit timing netlist accounts for actual path delays.

To run post-fit timing analysis, follow these steps:

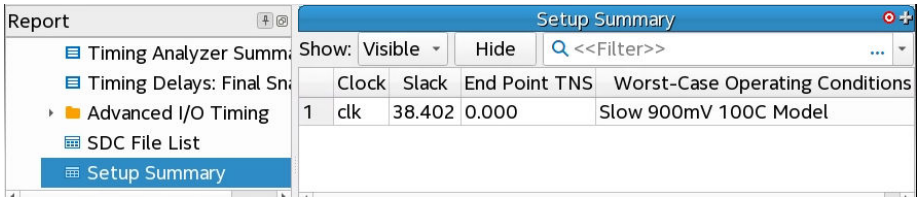
1. Specify conventional SDC timing constraints for post-fit timing analysis, as Specifying Conventional SDC Timing Constraints describes.
2. On the Compilation Dashboard, run any stage of the **Fitter** (**Plan**, **Place**, **Route**, **Retime**, **Fitter (Finalize)**) or run a full compilation.

Figure 44. Fitter Stages in Compilation Dashboard



3. When the Fitter completes, click the Timing Analyzer icon next to the completed stage in the Compilation Dashboard. The Setup Summary report opens by default in the Timing Analyzer.
4. Review the timing reports. To generate additional timing reports for analysis, click the **Reports** menu, and then click one of the submenu items to generate that report, as Step 4: Analyze Timing Reports describes.

Figure 45. Setup Summary Report

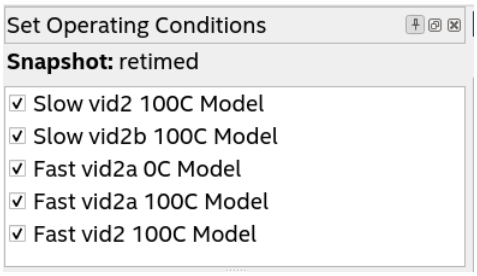


5. To run timing analysis under different operation conditions, click **Set Operating Conditions** on the **Tasks** pane and specify options, as Setting the Operating Conditions for Timing Analysis describes. By default, the Timing Analyzer generates reports for all supported operating conditions.
6. If you specify any settings or constraints that impact timing analysis, click **Update Timing Netlist** on the **Tasks** pane to apply the new constraints to the timing netlist.

2.2.3.2.1. Setting the Operating Conditions for Timing Analysis

Click **View ➤ Timing Corners** in the Timing Analyzer to specify the operating conditions for the timing analysis under different power and temperature ranges. The available operating conditions vary by device and speed grade. The various operating conditions that you can select represent the different "timing corners" in a multi-corner timing analysis.

Figure 46. Set Operating Conditions Panel



The Timing Analyzer displays the selectable operating conditions that are appropriate for your device in the **Set Operating Conditions** panel, according to the following timing model name conventions:

<process in speed grade> <voltage/vid> <temperature>

The following examples illustrate this naming convention:

- **Fast 900mV 40C Model**
  - **Fast**—timing model for the fastest process within a speed grade.
  - **900mV**—nominal 900mV timing model.
  - **40C**—low temperature (40 Celsius) timing model.

- **Slow vid<*n*> 100C Model**
  - **Slow**—timing model for the slowest process within a speed grade.
  - **vid**—timing model for analysis with SmartVID.
  - **<*n*>**—the device speed grade of the timing model.
  - **100C**—high temperature (100 Celsius) timing model.

Select one or more voltage and temperature combinations and double-click **Report Timing...** under **Timing Slack** in the **Tasks** pane to configure the generation of timing analysis reports for that model. The generated report shows the worst-case timing path slack across all operating conditions that you specify. After generating the report for that model, the report shows the worst-case timing path slacks across all operating conditions that you select.

You can use the following context menu options to generate or regenerate reports in the **Report** window:

- **Regenerate**—regenerates the report you select.
- **Regenerate All Out of Date**—regenerates all reports that are outdated because of SDC changes since the last generation.
- **Delete All Out of Date**—removes all outdated report data.

As an alternative to the GUI, you can run the `set_operating_conditions` command with the `-model`, `-speed`, `-temperature`, and `-voltage` options to specify the operating conditions. When running `set_operating_conditions`, you must only specify valid operating conditions for the current device. Run the `get_available_operating_conditions` command to return a list of all valid operating conditions for the current device.

The following example sets the operating condition to the slow timing model, with a voltage of 900 mV, and temperature of 100° C:

```
set_operating_conditions -model slow -temperature 100 -voltage 900
```

2.2.3.2.2. Promoting Critical Warnings to Errors

You can promote critical warnings to errors so that the Timing Analyzer halts on receiving the critical warnings (as it does for all errors). All critical warnings support promotion to error. However, you can only promote the message IDs of open projects.

1. In the **Message** dialog box, right-click on the critical warning you want to promote to an error.
2. Click **Message Promotion ➤ Promote Critical Message ID to Error**
3. To clear all promotions, click **Message Promotion ➤ Clear All Message Promotions**
4. Alternatively, promote or demote a critical warning in the `.qsf` with the following:

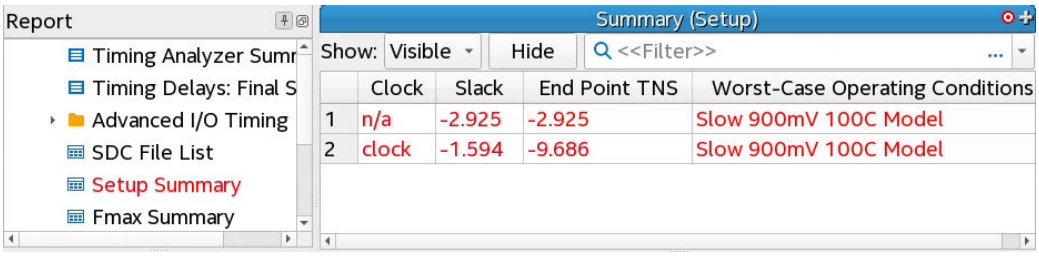
   ```
   set_global_assignment -name PROMOTE_WARNING_TO_ERROR <ID_Number>
   ```

2.2.4. Step 4: Analyze Timing Reports

During analysis, the Timing Analyzer examines the timing paths in the design, calculates the propagation delay along each path, checks for timing constraint violations, and reports timing results as positive slack or negative slack. Negative slack indicates a timing violation. Positive slack indicates that timing requirements are met.

The Timing Analyzer provides very fine-grained reporting and analysis capabilities to identify and correct violations along timing paths. Generate timing reports to view how to best optimize the critical paths in your design. If you modify, remove, or add constraints, re-run timing analysis. This iterative process helps resolve timing violations in your design.

Figure 47. Timing Analyzer Shows Failing Paths in Red



Reports that indicate failing timing performance appear in red text, and reports that pass appear in black text. A gold question mark icon indicates reports that are outdated due to SDC changes since generation. Regenerate these reports to show the latest data.

The following sections describe how to generate various timing reports for analysis.

Timing Report Descriptions on page 126

2.2.4.1. Cross-Probing with Design Assistant

The Quartus Prime Design Assistant can automatically report any violations against a standard set of Intel FPGA-recommended design guidelines during stages of compilation. You can specify which rules you want the Design Assistant to check in your design, and customize the severity levels, thus eliminating or waiving rule checks that are not important for your design.

When you run Design Assistant during compilation, Design Assistant utilizes the in-flow (transient) data that generates during compilation to check for rule violations.

When you run Design Assistant in analysis mode from the Timing Analyzer, Design Assistant performs design rule checks using the static compilation snapshot data that you load.

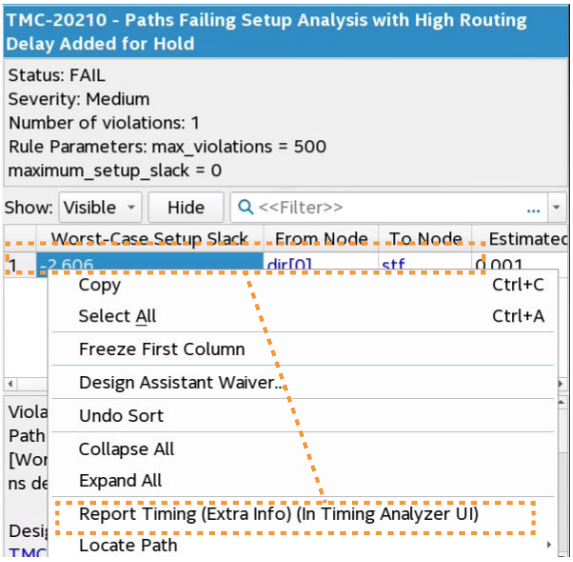
Some Design Assistant rule violations allow cross-probing into the related timing analysis data. Cross-probing can help you to more quickly identify the root cause and resolve any Design Assistant rule violations. For example, for a path with a setup analysis violation, you can cross-probe into the Timing Analyzer to identify the edge that has delay added for hold time.

Note: You must run the Compiler through at least the Plan stage before you can cross-probe to Timing Analyzer.

2.2.4.1.1. Cross-Probing from Design Assistant to Timing Analyzer

Some Design Assistant rule violations allow cross-probing into Timing Analyzer. For example, for a path that Design Assistant flags with a setup analysis violation due to delay added for hold, you can cross-probe into the Timing Analyzer to view more information on the affected path and edge.

Figure 48. Cross Probing from Design Assistant Rule TMC-20210 Violations to Timing Analyzer



Follow these steps to cross-probe from such Design Assistant rule violations to the Timing Analyzer:

1. Compile the design through at least the Compiler's Plan stage.
2. Locate a rule violation in the Design Assistant folder of the Compilation Report.
3. Right-click the rule violation to display any **Report Timing** commands available for the violation.
4. Click the **Report Timing** command. The Timing Analyzer opens and reports the timing data for the violation path. **Report Timing (Extra Info)** includes Estimated Delay Added for Hold and Route Stage Congestion Impact extra data.

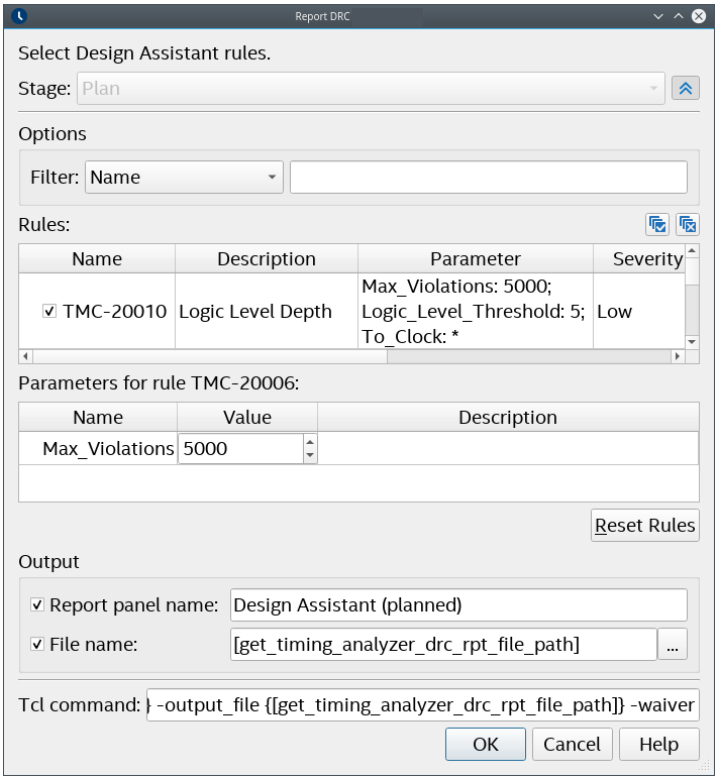
2.2.4.2. Launching Design Assistant from Timing Analyzer

You can run Design Assistant directly from the Timing Analyzer to assist when optimizing timing paths and other timing conditions. When you launch Design Assistant from the Timing Analyzer, Design Assistant only checks rules that relate to timing analysis.

Follow these steps to run the Design Assistant from the Timing Analyzer:

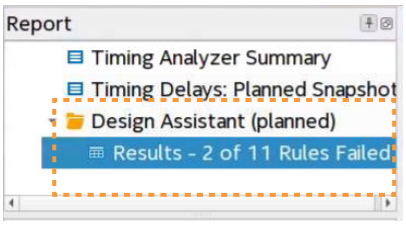
1. Compile the design through at least the Compiler's Plan stage.
2. Open the Timing Analyzer for the Compiler stage from the Compilation Dashboard.
3. In the Timing Analyzer, click **Reports ➤ Design Assistant ➤ Report DRC**. The **Report DRC** (design rule check) dialog box opens.
4. Under **Rules**, disable any rules that are not important to your analysis by removing the check mark.
5. Consider whether to adjust rule parameter values in the **Parameters** field.

Figure 49. Report DRC (Design Rule Check) Dialog Box



6. Confirm the **Report panel name** and optionally specify an output **File name**.
7. Click **Run**. The Results reports generate and appear in the **Report** pane, as well as the main Compilation Report.

Figure 50. Design Assistant Reports in Timing Analyzer Report Pane

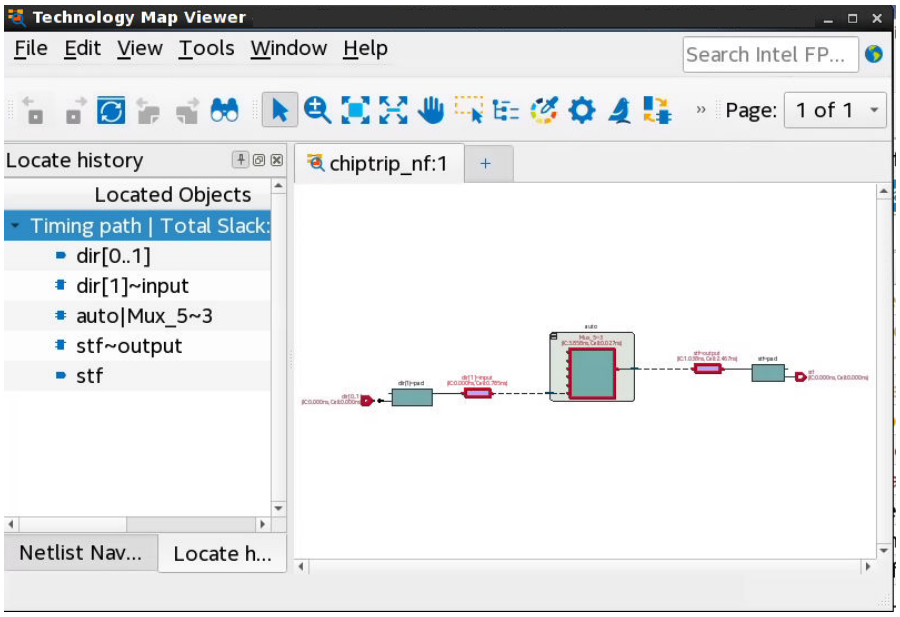


2.2.4.3. Locating Timing Paths in Other Tools

You can locate from paths and elements in the Timing Analyzer to other visualization tools in the Quartus Prime software, such as the Chip Planner, Technology Map Viewer, or Resource Property Viewer.

You can right-click most paths or node names in the Timing Analyzer reports and click the **Locate Node** or **Locate Path** commands. Use these commands in the Timing Analyzer GUI or the `locate` command in the Tcl console to locate to that node in other Quartus Prime tools.

Figure 51. Locate Path from Timing Analyzer to Technology Map Viewer



The following examples show how to locate the ten paths with the worst timing slack from Timing Analyzer to the Technology Map Viewer, and locate all ports matching data* in the Chip Planner.

Example 1. Locating from the Timing Analyzer

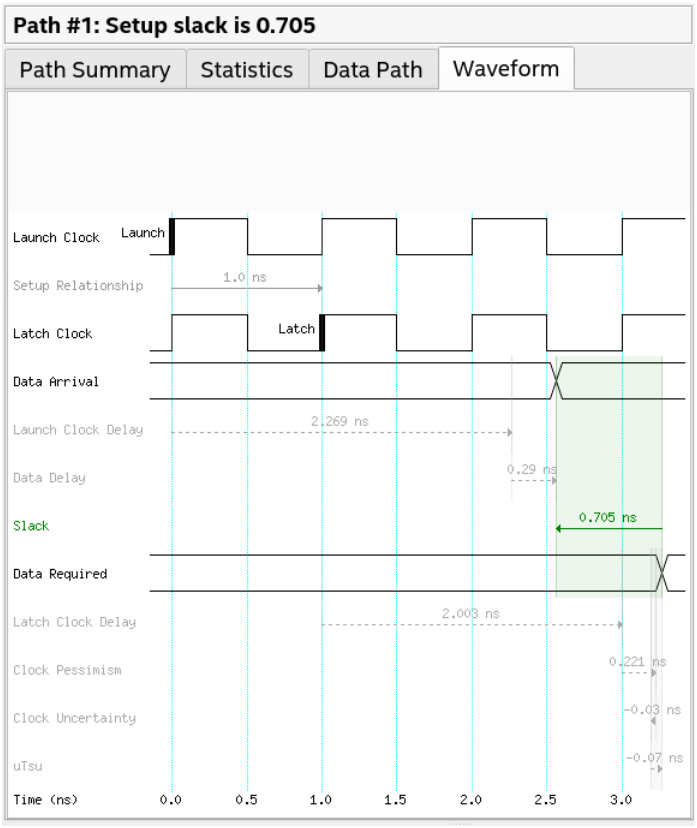
```
# Locate in the Technology Map Viewer the ten paths with the worst slack
locate [get_timing_paths -npaths 10] -tmv
# locate all ports that begin with data in the Chip Planner
locate [get_ports data*] -chip
```

2.2.4.4. Correlating Constraints to the Timing Report

Understanding how timing constraints and violations appear in the timing analysis reports is critical to understanding the results. The following examples show how specific constraints impact the timing analysis reports. Most timing constraints only affect the clock launch and latch edges. Specifically, `create_clock` and `create_generated_clock` create clocks with default relationships. However, the `set_multicycle_path` exception modifies the default setup and hold relationships. The `set_max_delay` and `set_min_delay` constraints are low-level overrides that explicitly indicate the maximum and minimum delays for the launch and latch edges.

The following figures show the results of running **Report Timing** on a particular path. You can view the incremental delays on the **Data Path** and **Waveform** tabs after running **Report Timing**. The **Waveform** tab allows you to visually reference the **Data Path** data, as well as the original `.sdc` constraints. You can use the **Waveform** tab to easily see how and where the constraints apply.

Figure 52. Report Timing (Waveform Tab)



In the following example, the design includes a clock driving the source and destination registers with a period of 10 ns. This results in a setup relationship of 10 ns (launch edge = 0 ns, latch edge = 10ns) and hold relationship of 0 ns (launch edge = 0 ns, latch edge = 0 ns) from the command:

```
create_clock -name clocktwo -period 10.000 [get_ports {clk2}]
```

Figure 53. Setup Relationship 10ns

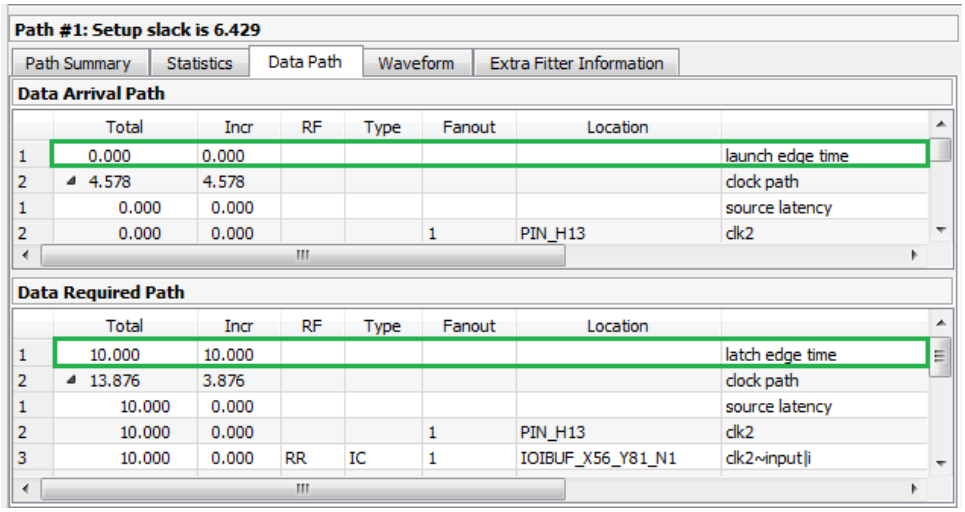


Figure 54. Hold Relationship 0ns

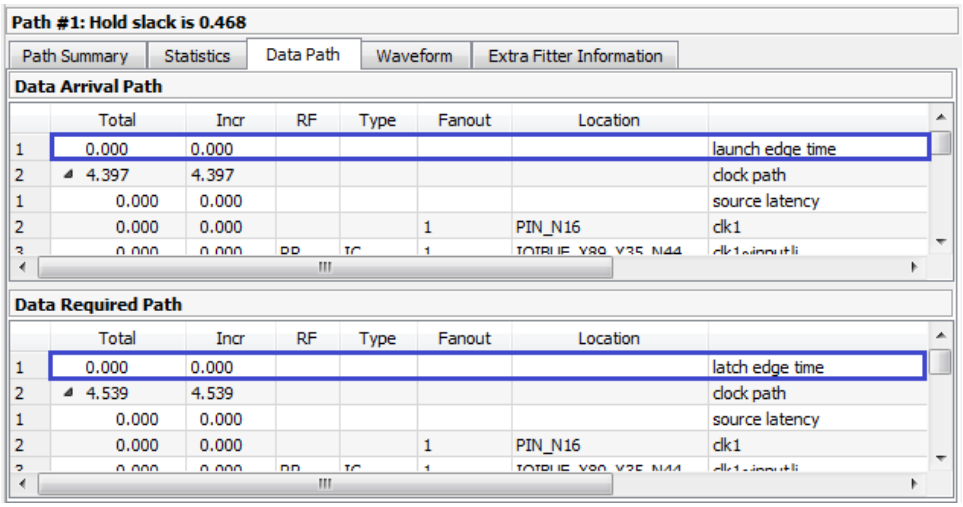
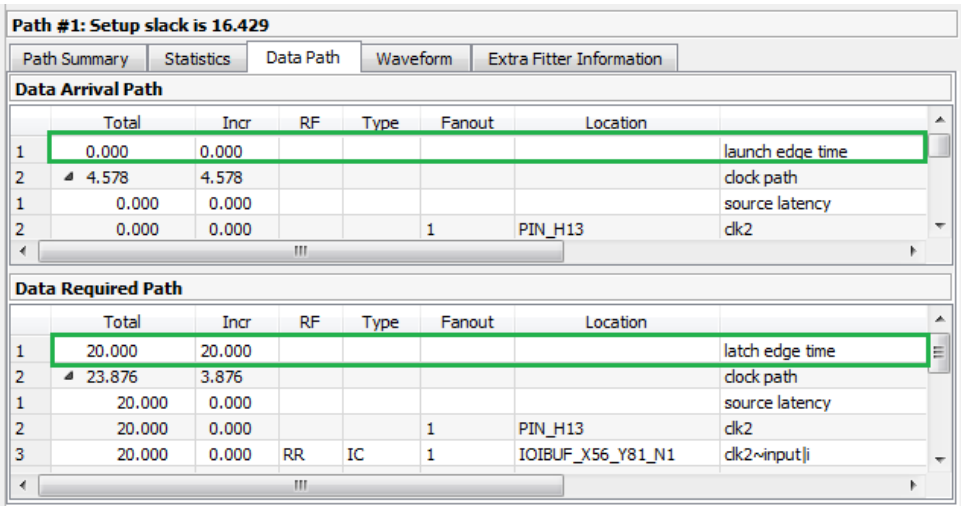


Adding `set_multicycle_path` constraints adds multicycles to relax the setup relationship, or open the window, making the setup relationship 20 ns while maintaining the hold relationship at 0 ns:

```
set_multicycle_path -from clocktwo -to clocktwo -setup -end 2
set_multicycle_path -from clocktwo -to clocktwo -hold -end 1
```

Figure 55. Setup Relationship 20ns

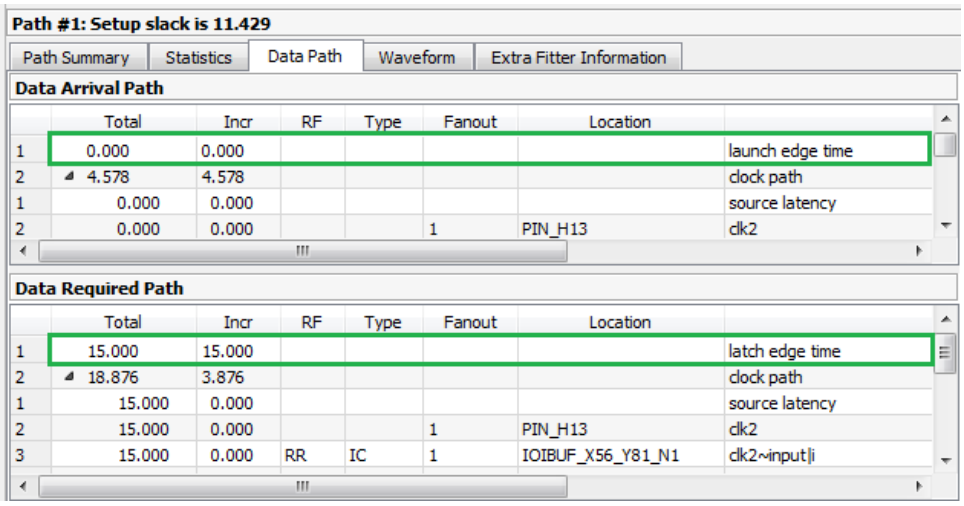


Adding the following `set_max_delay` constraints explicitly overrides the setup relationship:

```
set_max_delay -from [get_registers {regA}] -to \
     [get_registers {regB}] 15
```

Note that the only thing changing for these different constraints are the launch edge time and latch edge times for setup and hold analysis. Every other line item comes from delays inside the FPGA and are static for a given fit. View these reports to analyze how your constraints affect the timing reports.

Figure 56. Using set_max_delay



For I/O, you must add `set_input_delay` and `set_output_delay` constraints, as the following example shows. These constraints describe delays on signals from outside of the FPGA design that connect to the design's I/O ports.

```
create_clock -period 10 [get_ports clk]
# Clock used by the transfer, clock relationship is 10ns

# Setup constraints
set_output_delay -clock clk -max 1.2 [get_ports out]
# Subtracted from Data Required Path as oExt
set_max_delay -from [get_registers B] 12
# Sets latch edge time

# Hold constraints
set_output_delay -clock clk -min 2.3 [get_ports out]
# Subtracted from Data Required Path as oExt
set_min_delay -from [get_registers B] 8
# Sets latch edge time
```

The values of these constraints are the delays of the external signals between an external register and a port on the design. The `-clock` argument to the `set_input_delay` and `set_output_delay` specifies the clock domain that the external signal belongs to, or rather, the clock domain of the external register connected to the I/O port. The `-min` and `-max` options specify the worst-case or best-case delay; not specifying either option causes the worst- and best-case delays to be equal. I/O delays display as **iExt** or **oExt** in the **Type** column, as the following example reports shows.

5	3.407	0.000	RR	CELL	0	PIN_AC6		out

Data Required Path

	Total	Incr	RF	Type	Fanout	Location	HS/LP	Element
1	8.000	8.000						latch edge time
2	8.000	0.000						clock path
1	8.000	0.000	R					clock network delay
3	8.030	0.030						clock uncertainty
4	5.730	-2.300	R	oExt	0	PIN_AC6		out

A clock relationship, which is the difference between the launching and latching clock edge of a transfer, is determined by the clock waveform, multicycle constraints, and minimum and maximum delay constraints. The Timing Analyzer also adds the value of `set_output_delay` as an **oExt** value. For outputs, this value is part of the **Data Required Path**, since this is the external part of the analysis. The setup report subtracts the `-max` value, making the setup relationship harder to meet, since the **Data Arrival Path** delay must be shorter than the **Data Required Path** delay. The Timing Analyzer also subtracts the `-min` value. This subtraction is why a negative number causes more restrictive hold timing. The **Data Arrival Path** delay must be longer than the **Data Required Path** delay.

2.3. Applying Timing Constraints

This section provides examples and describes how to correctly apply SDC timing constraints that guide design synthesis, Fitter placement, and produce accurate timing analysis results under various circumstances.
You can define a set of initial timing constraints, and then iteratively modify those constraints as the design progresses.

Early in the design cycle, you can use SDC-on-RTL constraints to target analysis of RTL nodes. This analysis provides a stable reference for constraints that can remain unchanged in subsequent compilation stages, such as clock definitions. Establishing a set of SDC-on-RTL constraints enables their propagation and application throughout the entire design cycle. Concurrently, you can create a conventional `.sdc` file for analysis of the remaining design elements, providing flexibility for iterative constraint adjustments as the design evolves.

This section also outlines the proper application of recommended conventional SDC timing constraints. Conventional SDC constraints guide Fitter placement via `.sdc` files, offering alternative approaches to achieve precise control over constraints throughout the design flow.

Related Information

- Using Timing Constraints throughout the Design Flow on page 27
- Applying Entity-Bound Timing Constraints on page 56
- Recommended Initial Conventional SDC Constraints on page 49

2.3.1. Recommended Initial Conventional SDC Constraints

Include the following basic SDC constraints in your conventional `.sdc` file. The following example shows application of the recommended conventional SDC constraints for a simple dual-clock design:

```
create_clock -period 20.00 -name adc_clk [get_ports adc_clk]
create_clock -period 8.00 -name sys_clk [get_ports sys_clk]

derive_pll_clocks

derive_clock_uncertainty
```

Note: Only Arria 10 and Cyclone® 10 GX devices support the **Derive PLL Clocks** (`derive_pll_clocks`) constraint. For all other supported devices, the Timing Analyzer automatically derives PLL clocks from constraints bound to the related IP.

Create Clock (create_clock) on page 50

Derive PLL Clocks (derive_pll_clocks) on page 50

Derive Clock Uncertainty (derive_clock_uncertainty) on page 51

Set Clock Groups (set_clock_groups) on page 52

2.3.1.1. Create Clock (create_clock)

The **Create Clock** (`create_clock`) constraint allows you to define the properties and requirements for a clock in the design. You must define clock constraints to determine the performance of your design and constrain the external clocks coming into the FPGA. You can enter the constraints in the Timing Analyzer GUI, or in the `.sdc` file directly.

You specify the **Clock name** (`-name`), clock **Period** (`-period`), rising and falling **Waveform edge** values (`-waveform`), and the target signal(s) to which the constraints apply.

The following command creates the `sys_clk` clock with an 8ns period, and applies the clock to the `fpga_clk` port.:

```
create_clock -name sys_clk -period 8.0 \
     [get_ports fpga_clk]
```

Note: Tcl and `.sdc` files are case-sensitive. Ensure that references to pins, ports, or nodes match the case of names in your design.

By default, the `sys_clk` example clock has a rising edge at time 0 ns, a 50% duty cycle, and a falling edge at time 4 ns. If you require a different duty cycle, or to represent an offset, specify the `-waveform` option.

Typically, you name a clock with the same name as the port you assign. In the example above, the following constraint accomplishes this:

```
create_clock -name fpga_clk -period 8.0 [get_ports fpga_clk]
```

There are now two unique objects called `fpga_clk`, a port in your design and a clock applied to that port.

Note: In Tcl syntax, square brackets execute the command inside them. `[get_ports fpga_clk]` executes a command that finds and returns a collection of all ports in the design that match `fpga_clk`.

Warning: Constraints that you define in the Timing Analyzer apply directly to the timing database, but do not automatically transfer to the `.sdc` file. Click **Write SDC File** on the Timing Analyzer **Tasks** pane to preserve constraints changes from the GUI in an `.sdc` file.

Related Information

Creating Base Clocks on page 79

2.3.1.2. Derive PLL Clocks (derive_pll_clocks)

The **Derive PLL Clocks** (`derive_pll_clocks`) constraint automatically creates clocks for each output of any PLL in your design.

Note: Only Arria 10 and Cyclone 10 GX devices support the **Derive PLL Clocks** (`derive_pll_clocks`) constraint. For all other supported devices, the Timing Analyzer automatically derives PLL clocks from constraints bound to the related IP.

The constraint can generate multiple clocks for each output clock pin if the PLL is using clock switchover: one clock for the `inclk[0]` input clock pin, and one clock for the `inclk[1]` input clock pin. Specify the **Create base clocks** (`create_base_clocks`) option to create base clocks on the inputs of the PLLs by default. By default the clock name is the same as the output clock pin name, or specify the **Use net name as clock name** (`use_net_name`) option to use the net name.

When you create PLLs, you must define the configuration of each PLL output. This definition allows the Timing Analyzer to automatically constrain the PLLs with the `derive_pll_clocks` command. This command also constrains transceiver clocks and adds multicycles between LVDS SERDES and user logic.

The `derive_pll_clocks` command prints an Info message to show each generated clock the command creates.

As an alternative to `derive_pll_clocks` you can copy-and-paste each `create_generated_clock` assignment into the `.sdc` file. However, if you subsequently modify the PLL setting, you must also change the generated clock constraint in the `.sdc` file. Examples of this type of change include modifying an existing output clock, adding a new PLL output, or making a change to the PLL's hierarchy. Use of `derive_pll_clocks` eliminates this requirement.

Related Information

- Creating Base Clocks on page 79
- Deriving PLL Clocks on page 85

2.3.1.3. Derive Clock Uncertainty (derive_clock_uncertainty)

The **Derive Clock Uncertainty** (`derive_clock_uncertainty`) constraint applies setup and hold clock uncertainty for clock-to-clock transfers in the design. This uncertainty represents characteristics like PLL jitter, clock tree jitter, and other factors of uncertainty.

You can enable the **Add clock uncertainty assignment** (`-add`) to add clock uncertainty values from any **Set Clock Uncertainty** (`set_clock_uncertainty`) constraint. You can **Overwrite existing clock uncertainty assignments** (`-overwrite`) any `set_clock_uncertainty` constraints.

```
create_clock -period 10.0 -name fpga_sys_clk [get_ports fpga_sys_clk] \
    derive_clock_uncertainty -add - overwrite
```

The Timing Analyzer generates an information message if you omit `derive_clock_uncertainty` from the `.sdc` file.

Related Information

Accounting for Clock Effect Characteristics on page 90

2.3.1.4. Set Clock Groups (set_clock_groups)

The **Set Clock Groups** (`set_clock_groups`) constraint allows you to specify which clocks in the design are unrelated. By default, the Timing Analyzer assumes that all clocks with a common base or parent clock are related, and that all transfers between those clock domains are valid for timing analysis. You can exclude transfers between specific clock domains from timing analysis by cutting clock groups.

Conversely, clocks without a common parent or base clock are always unrelated, but timing analysis includes the transfers between such clocks, unless those clocks are in different clock groups (or if all of their paths are cut with false path constraints).

You define the clock signals to include in each Group (-group), then specify the relationship between different groups, and then specify whether the groups are **Logically exclusive** (`-logically_exclusive`), **Physically exclusive** (`-physically_exclusive`, or **Asynchronous** (`-asynchronous`) from one another.

```
set_clock_groups -asynchronous -group {<clock1>...<clockn>} ... \
    -group {<clocka>...<clockn>}
```

- `-logically_exclusive`—defines clocks that are logically exclusive and not active at the same time, such as multiplexed clocks
- `-physically_exclusive`—defines clocks that that cannot be physically on the device at the same time.
- `-asynchronous`—defines completely unrelated clocks that have different ideal clock sources. This flag means the clocks are both switching, but not in a way that can synchronously pass data.

For example, if there are paths between an 8ns clock and 10ns clock, even if the clocks are completely asynchronous, the Timing Analyzer attempts to meet a 2ns setup relationship between these clocks, unless you specify that they are not related.

The following shows example constraints for a clock mux with two inputs, with multi-rate clocks, and the appropriate combinations of logical and physical exclusivity:

```
# First profile
create_clock -name clk_a1 -period 10 [get_ports clk_a]
create_clock -name clk_b1 -period 20 [get_ports clk_b]

# Second profile
create_clock -name clk_a2 -period 100 [get_ports clk_a] -add
create_clock -name clk_b2 -period 200 [get_ports clk_b] -add

# Mark base clocks as asynchronous to each other
set_clock_groups -asynchronous -group {clk_a?} -group {clk_b?}

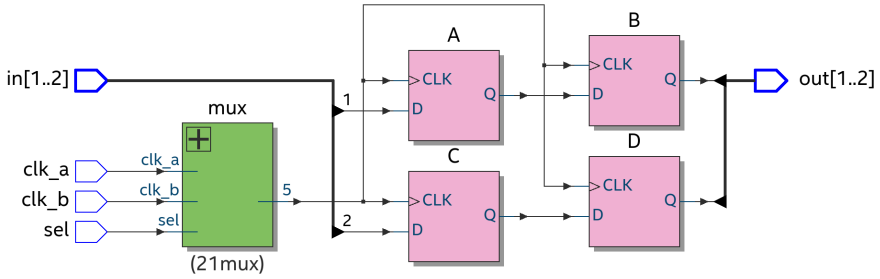
# Define muxed clocks for each profile
set muxout [get_pins -compatibility_mode {mux*|combout}]
foreach profile {1 2} {
     set mux_clk_a "mux_clk_a${profile}"
     set mux_clk_b "mux_clk_b${profile}"

     create_generated_clock -name $mux_clk_a -source [get_ports clk_a] \
          -master_clock "clk_a${profile}" $muxout -add
     create_generated_clock -name $mux_clk_b -source [get_ports clk_b] \
          -master_clock "clk_b${profile}" $muxout -add

     # Mark each muxed clock as logically exclusive to each other
     set_clock_groups -logically_exclusive -group $mux_clk_a \
          -group $mux_clk_b
}
```

```
# Mark profile clocks as physically exclusive to each other
# (Do this after defining the derived clocks so they get cut too)
set_clock_groups -physically_exclusive -group {*clk_?1} \
     -group {*clk_?2}
```

Figure 59. Example Constraints Design Topology



Although the **Set Clock Groups** dialog box only permits two clock groups, you can specify an unlimited number of `-group {<group of clocks>}` options in the `.sdc` file. If you omit an unrelated clock from the assignment, the Timing Analyzer acts conservatively and analyzes that clock in context with all other domains to which the clock connects.

The Timing Analyzer does not currently analyze crosstalk explicitly. Instead, the timing models use extra guard bands to account for any potential crosstalk-induced delays. The Timing Analyzer treats the `-asynchronous` and `-exclusive` options the same for crosstalk-related analysis, but treats asynchronous and exclusive clock groups differently for things like max skew reporting and synchronizer detection.

A clock cannot be within multiple groups (`-group`) in a single assignment; however, you can have multiple `set_clock_groups` assignments.

Another way to cut timing between clocks is to use `set_false_path`. To cut timing between `sys_clk` and `dsp_clk`, you can use:

```
set_false_path -from [get_clocks sys_clk] -to [get_clocks dsp_clk]
```

```
set_false_path -from [get_clocks dsp_clk] -to [sys_clk]
```

This technique is effective if there are only a few clocks, but can become unmanageable with a large number of constraints. In a simple design with three PLLs that have multiple outputs, the `set_clock_groups` command can cut timing between clocks with less than ten lines, but the `set_false_path` command may require more than 50 lines.

2.3.2. Example Circuit and Conventional SDC File

The following `.sdc` file demonstrates constraining a dual-clock, phase-locked loop (PLL) example that illustrates. and other common synchronous design elements.

Example 2. Conventional .sdc Constraints Example

```
# Create clock constraints
create_clock -name clockone -period 10.000Ns [get_ports {clk1}]
create_clock -name clocktwo -period 10.000Ns [get_ports {clk2}]
# Create virtual clocks for input and output delay constraints
create clock -name clockone_ext -period 10.000Ns
create clock -name clocktwo_ext -period 10.000Ns
# derive PLL clocks to create the altpll0| clock referenced later
derive_pll_clocks
# derive clock uncertainty
derive_clock_uncertainty
# Specify that clockone and clocktwo are unrelated by assigning
# them to separate asynchronous groups
set_clock_groups \
  -asynchronous \
  -group {clockone} \
  -group {clocktwo altpll0|altpll_component|auto_generated|pll1|clk[0]}
# set input and output delays
set_input_delay -clock { clockone_ext } -max 4 [get_ports {data1}]
set_input_delay -clock { clockone_ext } -min -1 [get_ports {data1}]
set_input_delay -clock { clockone_ext } -max 4 [get_ports {data2}]
set_input_delay -clock { clockone_ext } -min -1 [get_ports {data2}]
set_output_delay -clock { clocktwo_ext } -max 6 [get_ports {dataout}]
set_output_delay -clock { clocktwo_ext } -min -3 [get_ports {dataout}]
```

The conventional `.sdc` file contains the following constraints that you typically include for most designs:

- Definitions of `clockone` and `clocktwo` as base clocks, and assignment of those constraints to nodes in the design.
- Definitions of `clockone_ext` and `clocktwo_ext` as virtual clocks, which represent clocks driving external devices interfacing with the FPGA.
- Automated derivation of generated clocks on PLL outputs.
- Derivation of clock uncertainty.
- Specification of two clock groups, the first containing `clockone` and its related clocks, the second containing `clocktwo` and the output of the PLL. This specification overrides the default analysis of all clocks in the design as related to each other.
- Specification of input and output delays for the design.

Asynchronous Clock Groups (-asynchronous) on page 89

2.3.3. SDC File Precedence

To ensure proper integration into the compilation flow, you must add any SDC-on-RTL and conventional SDC files to your project, as Step 1: Specifying General Timing Analyzer Settings describes. Alternatively, you can add files to your project by modifying the assignments in the project `.qsf` file directly.

The Compiler processes conventional SDC files in the order listed in the `.qsf`. You can add, remove, or change the processing order of `.sdc` files using **Assignments ➤ Settings ➤ Timing Analyzer**, or by modifying the `.qsf` directly.

Note: SDC-on-RTL files take precedence and the Compiler always processes `.rtlsdc` files before conventional `.sdc` files that target the timing netlist, regardless of order in **Assignments ➤ Settings ➤ Timing Analyzer**.

When using the `read_sdc` command at the command line without any arguments, the Compiler reads constraints in the following sequence:

1. Initially, the Compiler reads any SDC-on-RTL constraints.
2. Next, the Compiler reads any synthesis-only constraints that apply to only the synthesis stage.
3. Next, the Compiler reads any conventional SDC constraints. For conventional SDC constraints, the following order applies:

a. First, the Compiler processes constraints embedded in HDL files.
b. Finally, the Compiler processes `.sdc` files based on file order.

2.3.4. Iteratively Modifying Constraints

You initially establish SDC-on-RTL constraints during the Analysis & Elaboration stage of the compilation flow. Making iterative changes to SDC-on-RTL constraints may require you to rerun Analysis & Elaboration multiple times to apply revised constraints to the netlist.

It is best to designate constraints that remain constant across compilation stages as SDC-on-RTL constraints. Subsequently, you can iteratively modify and reanalyze the constraints in the rest of your design using conventional constraint files.

To iteratively modify constraints, follow these steps

1. Click **Tools ➤ Timing Analyzer**.
2. Generate the reports you want to analyze. Double-click **Report All Summaries** under **Macros** to generate setup, hold, recovery, and removal summaries, summaries for supported reports, and a list of all the defined clocks in the design. These summaries cover all paths you constrain in your design. Whenever modifying or correcting constraints, generate the **Constraint Diagnostic** reports to identify unconstrained parts of your design, or ignored constraints.
3. Analyze the results in the reports. When done modifying constraints, rerun the reports to find any unexpected results. For example, a cross-domain path might indicate that you forgot to cut a transfer by including a clock in a clock group.
4. Create or edit the appropriate constraints in your `.sdc` file and save the file.
5. Double-click **Reset Design** in the **Tasks** pane. This removes all constraints from your design. Removing all constraints from your design allows rereading the SDC files, including your changes.
6. Regenerate the reports you want to analyze.
7. Reanalyze the results.
8. Repeat steps 4-7 as necessary.

Using this approach, timing analysis runs with updated constraints, preserving the existing logic placement. The Fitter relies on the original constraints for design place-and-route, while the Timing Analyzer incorporates the newly applied constraints. If any timing issues arise in relation to the updated constraints, rerun the Fitter stage of compilation. Furthermore, for enhanced control over your design, consider converting select refined constraints to the SDC-on-RTL approach, as Specifying SDC-on-RTL Timing Constraints describes.

Relaxing Setup with Multicycle (set_multicyle_path) on page 104

2.3.5. Applying Entity-Bound Timing Constraints

Entity-bound timing constraints enable meticulous control of timing constraints by allowing you to confine (bind) a constraint set to a specific design entity or a group of entities. You can define entity-based SDC-on-RTL constraints that enable early timing analysis after running only Analysis & Elaboration. You can similarly use conventional SDCs for post-fit timing analysis.

Related Information

- Using Entity-Based SDC-on-RTL Constraints on page 57
- Using Entity-Bound SDC Files on page 64

2.3.5.1. Using Entity-Based SDC-on-RTL Constraints

A typical design includes a combination of third-party IPs and actively evolving RTL components. You can use entity-based SDC-on-RTL constraints to define precise timing constraints at module boundaries, helping to ensure the seamless integration of IP and constraints. Entity-based SDC-on-RTL constraints allow IP authors to encapsulate the SDC constraints for their IP.

Conventional SDC timing constraints generally apply globally throughout a design, rather than to specific entities. However, proper encapsulation of IP SDCs allows you to use the IP without encountering unexpected SDC leaks. Entity binding prefixes filters with the full path name of each IP, effectively limiting the scope of the SDC constraints. This entity binding effectively prevents any SDC leaks and any potential impact on design paths with a matching name.

IP authors can optimize these constraints for post-synthesis Early Timing Analysis within the context IP instantiation in the design hierarchy. Even if an IP author does not know where the IPs are instantiated yet, the constraints remain effective. This approach allows IP authors to implement SDC constraints without requiring detailed information about the eventual placement of the IP within the design hierarchy.

The Compiler reads entity-based SDC-on-RTL constraints in designs and IP cores during Analysis & Elaboration. The Compiler preserves the constraints in a low-level entity database. The Compiler processes these constraints in the SDC read-in order and applies the constraints to the hierarchical netlist objects during compilation.

QSF Assignment Syntax

```
set_instance_assignment -name RTL_SDC_FILE <sdc_file_name> \
   -entity <entity_name> [-no_sdc_promotion]
```

Where:

Argument	Description
`RTL_SDC_FILE`	Specifies the SDC-on-RTL file name.
`-entity`	Specifies an entity-based assignment. The SDC file applies to each instance of the design entity. The instance hierarchy path implicitly applies to the `pattern` argument search for `dni::get_*` (`get_cells`, `get_pins`, `get_ports`, and `get_nets`) commands.
`[-no_sdc_promotion]`	An optional argument that requires the `-entity` flag. For entity-based constraints, the `[-no_sdc_promotion]` argument removes the default behavior of the instance hierarchy path being the default implicit with the netlist search commands. This argument specifies which individual command to apply the instance hierarchy path in the netlist object search. Use the `get_entity_current_instance` Tcl command to obtain the current instance hierarchy path of the entity. For example: `set_false_path -from [get_pins [get_entity_current_instance]|ff_src|clk] \` `-to [get_pins [get_entity_current_instance]|ff_dst|d]]`

2.3.5.1.1. Targeting Constraints to Module Inputs and Outputs

SDC-on-RTL allows you to define constraints at module boundaries, even if some internal connections within the modules or IP remain partially unknown. It is best to apply SDC-on-RTL constraints at the module boundaries, specifically at the input and output boundaries of each module.

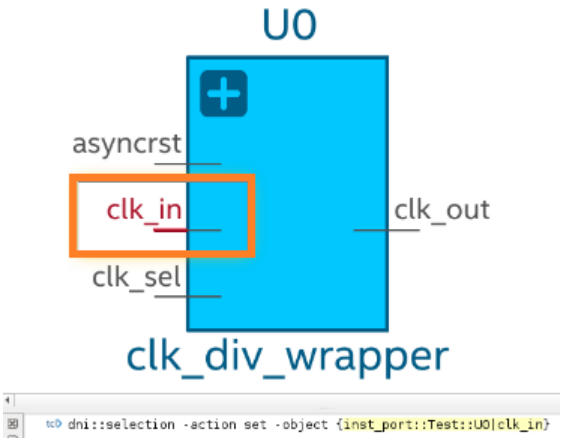
When targeting your timing constraints to the inputs and outputs of a module, you can target the following different element types, depending on your circumstances:

inst_port—these elements are retrieved in collections due to applying the `get_pins` filter. They target inputs and outputs of modules in a manner similar to addressing pins on registers and LUTs.

```
# inside
get_pins {clk_in} clk_dic.rtlsdc
```

Note: Use `get_pins` for constraints that expect pins as targets.

Figure 61. Targeting the Instance Port

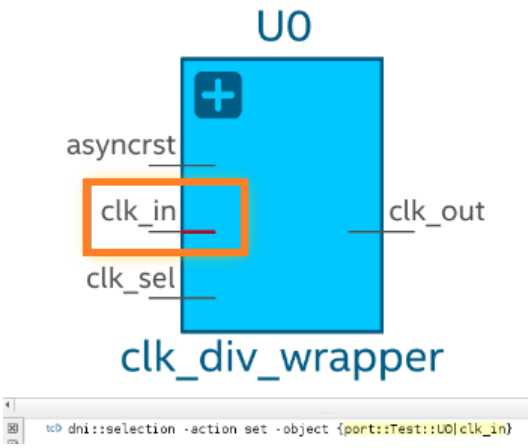


port— these elements reside within the module and are primarily for use in targeting ports in entity-bound constraints. You can employ the `get_ports` filter for this purpose.

```
# Inside
get_ports {clk_in} clk_dic.rtlsdc
```

Note: Use `get_ports` for constraints that expect ports as targets.

Figure 62. Targeting the Port



2.3.5.1.2. Entity Based SDC-on-RTL Constraint Scope

The entity-based SDC-on-RTL approach offers diverse scoping possibilities for determining the constraint's scope of influence.

Table 7. Entity-based Constraint Scope

Constraint Scope Type	Features	To Enable Instance-based Scoping
Automatic	• Accessible only by `.qsf` assignment. • Under automatic scoping, constraints apply to every instance of the assigned entity across the project. • Each result from any `get` command (for example, `get_pins`, `get_ports`, and so on) in the SDC file is prepended with the instance's path. • All `get` commands are confined to the target elements within the bound instance associated with the SDC-on-RTL file.	Use the following arguments: `name RTL_SDC_FILE <sdc_on_rtl_file_name>` `-entity <entity_name>` `-library <library_name>`
Manual	• Accessible only by `.qsf` assignment. • The `-no_sdc_promotion` setting disables automatic scoping, necessitating full hierarchical path for targeting nodes. • Allows targeting nodes beyond entity boundaries. • The `get_entity_current_instance` command delivers the top-level path to the current instance, allowing you to merge filters targeting elements in the current instance with commands addressing those beyond entity boundaries.	Use the following arguments: `-name RTL_SDC_FILE <sdc_on_rtl_file_name>` `-entity <entity_name>` `-library <library_name>` `-no_sdc_promotion` Prepend each collection filter with `get_entity_current_instance` to target nodes within the entity boundaries. For example: `get_pins [get_entity_current_instance]|reg[*]|q`

continued...

Constraint Scope Type	Features	To Enable Instance-based Scoping
Disabled	• Accessible by QSF assignment only. • `-no_sdc_promotion` and the `-no_auto_inst_discovery` arguments together disable scoping, treating an entity-bound SDC-on-RTL as a global scope. The SDC file is read only once for the entire compilation, rather processing for each instance linked. • This mode is ideal when bundling the SDC-on-RTL with an entity destined for export as a `.qdb` file, while preserving the ability to specify global, top-level paths in their `get` commands.	Use the following arguments: `-name RTL_SDC_FILE <sdc_on_rtl_file_name>` `-entity <entity_name>` `-library <library_name>` `-no_sdc_promotion` `-no_auto_inst_discovery`

When you define entity-bound SDC files, the software applies the constraints using automatic scoping, unless the `-no_sdc_promotion` or `-no_auto_inst_discovery` arguments are present.

Automatic scoping involves prepending filters with the instance's path. To provide clarity, the following table illustrates how paths are interpreted in various Tcl commands due to the automatic scoping of constraints:

Table 8. Automatic Scope of Constraints

Constraint Example	Auto-Scope Constraint Interpretation for Instance X|Y
`set_false_path -from [get_pins reg_a|clk]`	`set_false_path -from [get_pins X|Y|reg_a|clk]`
`set_false_path -from [get_pins reg_a|clk] -to [get_pins reg_b|d]`	`set_false_path -from [get_pins X|Y|reg_a|clk] -to [get_pins X|Y|reg_b|d]`
`set_false_path –from [get_clocks clk_1] –to [get_clocks clk_2]`	`set_false_path –from [get_clocks clk_1] –to [get_clocks clk_2]`
`set_max_delay –from [get_ports in] -to [get_pins reg_a|d] 2.0`	`set_max_delay –from [get_ports in] -to [get_pins X|Y|reg_a|d] 2.0`
`get_ports *`	`get_ports *`
`get_clocks *`	`get_clocks *`
`get_ports a`	`get_ports a`
`get_clocks a`	`get_clocks a`

When automatic scoping is disabled through QSF assignments, including the use of the `-no_sdc_promotion` argument, you must manually prepend the top-level path to achieve the same behavior as automatic scoping. To simplify this process, use the `-get_entity_current_instance` command that returns the top-level path of the

current instance. The following table illustrates how paths are interpreted when you use the `-get_entity_current_instance` command to add the top-level path to certain Tcl commands:

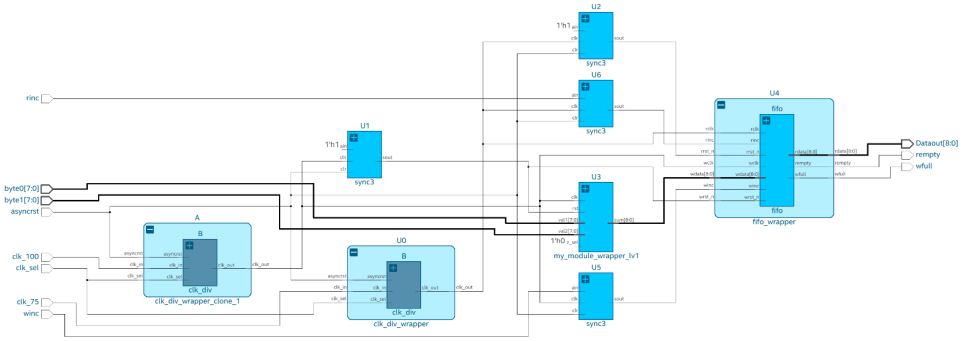
Table 9. Manual Scope of Constraints

Constraint Example	Manual Scope Constraint Interpretation
`set_false_path –from [get_entity_current_instance |reg_a|clk –to [get_entity_current_instance]|reg_b|d`	`set_false_path –from i1|inner|reg_a|clk –to i1|inner|reg_b|d` `set_false_path –from i2|inner|reg_a|clk –to i2|inner|reg_b|d` `set_false_path –from i3|reg_a|clk –to i3|reg_b|d`
`create_generated_clock –divide_by 2 –source \` `  [get_ports inclk] –name \` `  [get_entity_current_instance]_divclk \` `  [get_entity_current_instance]|div` `set_multicycle_path –from \` `  [get_entity_current_instance]|a \` `  –to [get_entity_current_instance]|b 2`	`# Evaluated for instances i1 and i2` `create_generated_clock –divide_by 2 –source \` `  [get_ports inclk] –name i1_divclk i1|div` `set_multicycle_path –from i1|a –to i1|b 2 \` `create_generated_clock –divide_by 2 –source \` `  [get_ports inclk] –name i2_divclk \` `  i2|div set_multicycle_path –from i2|a \` `  –to i2|b 2 \`

2.3.5.1.3. Automatic Scope Example for SDC-on-RTL

This example illustrates how to employ entity-based SDC-on-RTL constraints with automatic scope in your design. The following example uses two instances of `clk_div` and an additional `fifo` instance to illustrate how to apply this automatic scope approach:

Figure 63. Entity-Based SDC-on-RTL Design Example



1. Apply global SDC-on-RTL constraints to the design:

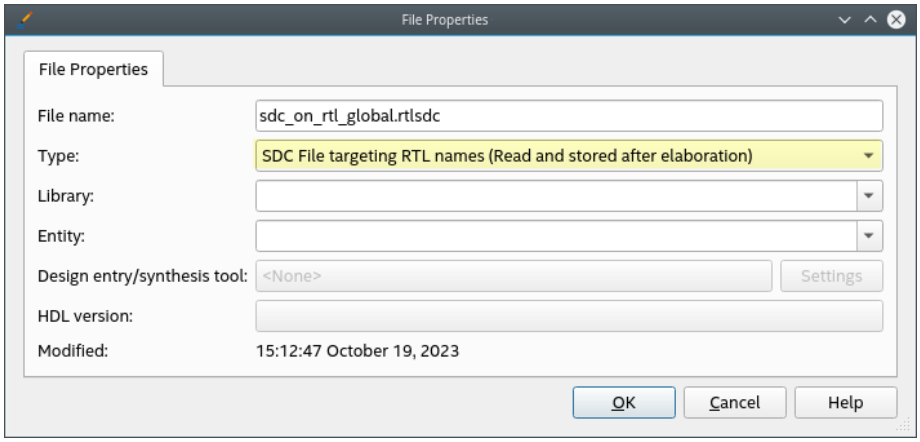
```
# sdc_on_rtl_global.rtlsdc

create_clock -period 100MHz [get_ports clk_100]
create_clock -period 75MHz [get_ports clk_75]
```

2. Use the **File Properties** dialog to assign this `.rtlsdc` file as the **SDC File Targeting RTL names** or use the following `.qsf` assignment:

```
set_global_assignment -name RTL_SDC_FILE <filename>
```

Figure 64. File Properties Dialog



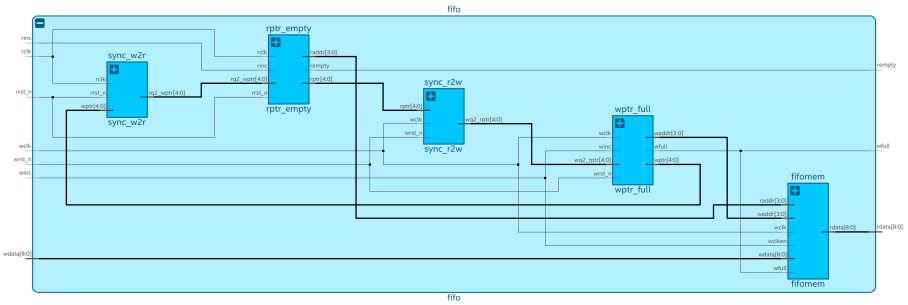
3. Define the following contents of the first entity based `.rtlsdc` file that is confined to the `clk_div` modules. In this case, the inner content of the module is unknown, but you can describe the known multiplexed clock behavior of the output in the `.rtlsdc`:

```
# clk_dic.rtlsdc
set current_instance [get_entity_current_instance];

create_generated_clock -name ${current_instance}_clk_mux_2 -source
[get_ports clk_in] -divide_by 2 [get_ports clk_out]
create_generated_clock -name ${current_instance}_clk_mux_1 -source
[get_ports clk_in] [get_ports clk_out] -add
```

In contrast, you can still define constraints using the following entity-bound approach for the `fifo` module that for which inner logic is already known. This approach can be advantageous, especially when multiple instances of the same module share identical constraints.

Figure 65. FIFO Module



```
set_false_path -from [get_pins wptr_full|wptr[*]|clk] -to [get_pins sync_w2r|
rq1_wptr[*]|d]
set_false_path -from [get_pins rptr_empty|rbin[4]|clk] -to [get_pins
sync_r2w|wq1_rptr[4]|d]
set_false_path -from [get_pins rptr_empty|rptr[*]|clk] -to [get_pins
```

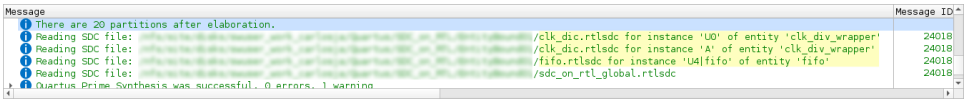
```
sync_r2w|wq1_rptr[*]|d]
set_false_path -from [get_pins wptr_full|wbin[4]|clk] -to [get_pins sync_w2r|
rq1_wptr[4]|d]
```

The following `.qsf` assignments add the `clk_div.rtlsdc` and `fifo.rtlsdc` files to the project, and define the file behavior as entity-based SDC-on-RTL:

```
set_global_assignment -name RTL_SDC_FILE clk_dic.rtlsdc -entity clk_div_wrapper -
library clk_div_wrapper
set_global_assignment -name RTL_SDC_FILE fifo.rtlsdc -entity fifo -library fifo
```

This assignment reduces the scope of each `.rtlsdc` file to the entities that match the assigned name. During Analysis & Elaboration, messages confirm that the Compiler appropriately applies each `.rtlsdc` file according to its assigned module.

Figure 66. Analysis & Elaboration Messages Confirm .rtlsdc Files Applied



You can further validate the correct application of each `.rtlsdc` file in the SDC File List report. The SDC File List report contains a comprehensive list, delineating each SDC file read, the file's assigned instance, and the file uses the SDC-on-RTL approach.

Figure 67. SDC File List Report

SDC File List

Show: Visible | Hide | <<Filter>> (use !<string> to invert filter)

	SDC File Path	Instance	Entity	Library	Promoted	Status	SDC on RTL	Processing Time
1	sdc_on_rtl_global.rtlsdc				No	OK	Yes	00:00:00
2	clk_dic.rtlsdc	U0	clk_div_wrapper	clk_div_wrapper	Yes	OK	Yes	00:00:00
3	clk_dic.rtlsdc	A	clk_div_wrapper	clk_div_wrapper	Yes	OK	Yes	00:00:00
4	fifo.rtlsdc	U4|fifo	fifo	fifo	Yes	OK	Yes	00:00:00

You can further confirm the correct application of constraints according to the constraint target and purpose in the Create Generated Clocks and Set False Paths reports.

Figure 68. Create Generated Clock Report

Create Generated Clock

Show: Visible | Hide | <<Filter>> (use !<string> to invert filter)

5	set_false_path	[get_pins {clk_sel|input clk_sel}]		sdc_on_rtl...l.rtlsdc:8
6	set_false_path	[get_ports {asyncrst}]		sdc_on_rtl...l.rtlsdc:9
7	set_false_path	[get_ports {rinc}]		sdc_on_rt...rtlsdc:10
8	set_false_path	[get_ports {winc}]		sdc_on_rt...rtlsdc:11

2.3.5.1.4. Manual Scope Example for SDC-on-RTL

You can change the scope of entity-based SDC-on-RTL files to manual by including the `-no_sdc_promotion` parameter in the `RTL_SDC_FILE` file definition. This parameter prevents the Compiler from prepending each collection filter with the full path of the current instance.

For example, to change to manual the scoping of the `clk_dic.rtlsdc` file associated with the `clk_div_wrapper` entity , add the `-no_sdc_promotion` parameter as follows:

```
set_global_assignment -name RTL_SDC_FILE clk_dic.rtlsdc -entity clk_div_wrapper \
-library clk_div_wrapper -no_sdc_promotion
```

To scope your collection filters precisely, use the `get_entity_current_instance` command. Specifying the top-level path to the present instance streamlines the process of scoping filters directed towards elements within instance boundaries.

```
set current_instance [get_entity_current_instance]
create_generated_clock -name ${current_instance}_clk_mux_2 -source \
  [get_ports $current_instance|clk_in] -divide_by 2 [get_ports $current_instance|
clk_out]

create_generated_clock -name ${current_instance}_clk_mux_1 -source \
[get_ports $current_instance|clk_in] [get_ports $current_instance|clk_out] -add
```

When the automatic scope is disabled for a designated entity-based SDC-on-RTL file, the SDC File List report indicates this change by displaying "No" in the promoted column.

Figure 70. SDC File List Report

SDC File List

Show: Visible | Hide | <<Filter>> (use !<string> to invert filter)

	SDC File Path	Instance	Entity	Library	Promoted	Status	SDC on RTL	Processing Time
1	sdc_on_rtl_global.rtlsdc				No	OK	Yes	00:00:00
2	clk_dic.rtlsdc	U0	clk_div_wrapper	clk_div_wrapper	No	OK	Yes	00:00:00
3	clk_dic.rtlsdc	A	clk_div_wrapper	clk_div_wrapper	No	OK	Yes	00:00:00
4	fifo.rtlsdc	U4|fifo	fifo	fifo	Yes	OK	Yes	00:00:00

2.3.5.2. Using Entity-Bound SDC Files

Throughout the design flow, most timing constraints specified in a Synopsis Design Constraints (SDC) file have a global scope across your project. However, if you want to associate a distinct set of constraints with a specific design entity, you can use the `SDC_ENTITY_FILE` assignment to assign SDC files to particular entity modules within your project.

Entity-bound SDC files significantly enhance the precision of timing constraints by allowing you to target constraints exclusively to specific entities where they are required. This approach bypasses the inadvertent ramifications of global constraints, which could encompass more targets than intended. As a result, you gain greater control over the precise locations within your design where these constraints take effect.

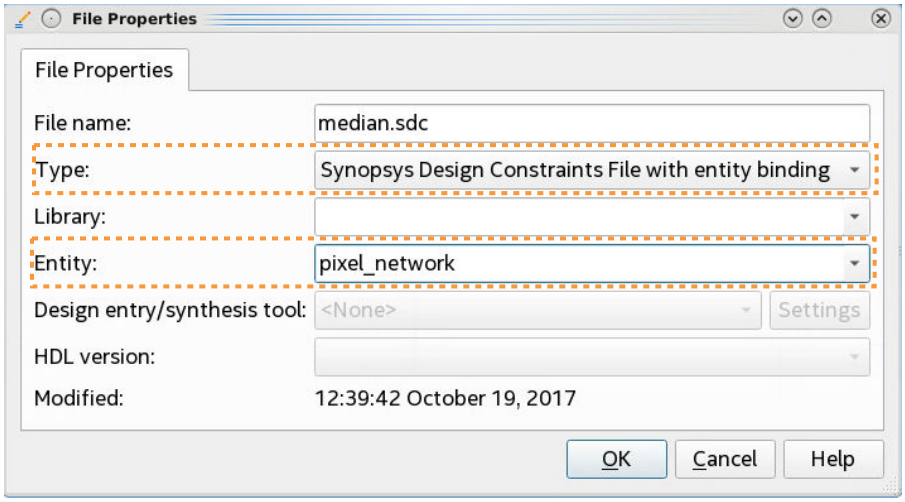
In addition to enhanced constraint precision, entity-bound SDC files also provide portability of the constraints. When you export a partition that contains entity-bound SDC constraints, you can optionally include these constraints in the exported file using

the **Include entity-bound SDC files for the selected partition** option in the **Export Design Partition** dialog box. Alternatively, you can specify this with the-`include_sdc_entity_in_partition` argument via a Tcl command.

To associate a specific SDC file with an entity using the entity-bound SDC file approach within the Quartus Prime Pro Edition software, follow these steps:

1. Generate a new SDC file and include it in your project by clicking **Project ➤ Add/ Remove files in project**.
2. Navigate to the files list and select the newly created SDC file.
3. Click the **Properties** button.
4. In the **Type** drop-down list, select **Synopsys Design Constraints File with entity binding**.

Figure 71. Entity Binding



5. In the **Entity** drop-down list, identify the entity you intend to bind to the SDC file.
6. Click **OK** to save the changes.

Alternatively, you can define the association between a specific SDC file and an entity by using the following assignment in the `.qsf` file:

QSF Assignment Syntax:

```
set_global_assignment -entity <entity_name> -name SDC_ENTITY_FILE
<sdc_file_name> \
-library <library_name> [-no_sdc_promotion] [-no_auto_inst_discovery]
```

Where:

Argument	Description
`-entity <entity_name>`	Mandatory argument. It defines the entity you want to bind to the SDC file.
`-name SDC_ENTITY_FILE <sdc_file_name>`	Specifies the SDC file name. The file's name is relative to the project path. In terms of scoping, the default setup for `SDC_ENTITY_FILE` is automatic constraint scoping. Automatic scoping means that each result from any `get` command (for example, `get_pins`, `get_ports`, and so on) in the SDC file is prepend with the instance's path. This confines all `get` commands to target items solely within the bound

continued...

Argument	Description
	instance associated with the SDC file. You can deactivate this configuration (which facilitates instance-level targeting) using the `-no_sdc_promotion` argument available through SDC commands. With this choice, you can handle the responsibility of manually scoping your collections either by explicitly providing the top-level path to the current instance or using the `get_current_instance` command that delivers the top-level path to the current instance. Such an approach proves invaluable when combining local commands with those that necessitate targeting global, top-level paths or objects outside the instance associated with the SDC file.
`-library <library_name>`	Indicates a library for the referenced entity. If you choose not to specify a library, the Quartus Prime Pro Edition software automatically defaults to the `altera_work` library.
`-no_sdc_promotion` `-no_auto_inst_discovery`	Converts any entity-bound SDC into a global SDC file read just once for the entire compilation, making it particularly fitting for bundling an SDC with an entity designated for export as a `qdb` file. This configuration still permits SDC's collection filters to specify global top-level paths in your `get` commands.

2.3.5.2.1. Entity-Bound SDC Constraint Scope

The entity-bound SDC approach offers diverse scoping possibilities for your constraints, each dictating the extent of their influence.

Table 10. Entity-bound Constraint Scope

Constraint Scope Type	Features	To Enable Instance-bound Scoping
Automatic	• Default mode applied to entity-bound SDC files defined in the Quartus Prime Pro Edition GUI. • Under automatic scoping, constraints apply to every instance of the assigned entity across the project. • Each result from any `get` command (for example, `get_pins`, `get_ports`, and so on) in the SDC file is prepended with the instance's path. • All `get` commands are confined to the target elements within the bound instance associated with the SDC file.	Default mode for `SDC_ENTITY_FILE`. No additional steps required.
Manual	• Accessible by QSF assignment only. • The `-no_sdc_promotion` setting disables automatic scoping, necessitating full hierarchical path for targeting nodes. • Allows the flexibility to target nodes beyond entity boundaries. • The `get_current_instance` command specifies the top-level path to the current instance, allowing you to merge filters targeting elements in the current instance with commands addressing those beyond entity boundaries.	Use `-no_sdc_promotion`. Append each collection filter with `get_current_instance` to target nodes within the entity boundaries. For example: `get_registers [get_current_instance]|reg[*]`
Disabled	• Accessible by QSF assignment only. • `-no_sdc_promotion` and the `-no_auto_inst_discovery` arguments together disable scoping, treating an entity-bound SDC as a global SDC file. The SDC file is read only once for the entire compilation instead of processing repeatedly for each instance it is linked to. • This mode is ideal when bundling an SDC with an entity destined for export as a `qdb` file, while preserving the capability for SDC's collection filters to specify global, top-level paths in their `get` commands.	Use `-no_sdc_promotion` and `-no_auto_inst_discovery` arguments.

When you define entity-bound SDC files either through the GUI or via `.qsf` assignments (excluding the `-no_sdc_promotion` and `-no_auto_inst_discovery` arguments), the constraints use automatic scoping. Automatic scoping involves

prepending filters with the instance's path. To provide clarity, the following table illustrates how paths are interpreted in various Tcl commands due to the automatic scoping of constraints:

Table 11. Automatic Scope of Constraints

Constraint Example	Auto-Scope Constraint Interpretation for Instance X|Y
`set_false_path -from [get_keepers a]`	`set_false_path -from [get_keepers X|Y|a]`
`set_false_path -from [get_registers a] -to [get_registers b]`	`set_false_path -from [get_registers X|Y|a] -to [get_registers X|Y|b]`
`set_false_path –from [get_clocks clk_1] –to [get_clocks clk_2]`	`set_false_path –from [get_clocks clk_1] –to [get_clocks clk_2]`
`set_max_delay –from [get_ports in] -to [get_registers A] 2.0`	`set_max_delay –from [get_ports in] -to [get_registers X|Y|A] 2.0`
`get_ports *`	`get_ports *`
`get_clocks *`	`get_clocks *`
`get_ports a`	`get_ports a`
`get_clocks a`	`get_clocks a`

When you disable automatic scoping through `.qsf` assignments, including the use of the `-no_sdc_promotion` argument, you must manually prepend the top-level path to achieve the same behavior as automatic scoping. To simplify this process, use the `-get_current_instance` command to return the top-level path of the current instance. The following table illustrates how paths are interpreted when the `-get_current_instance` command is employed to add the top-level path to certain Tcl commands:

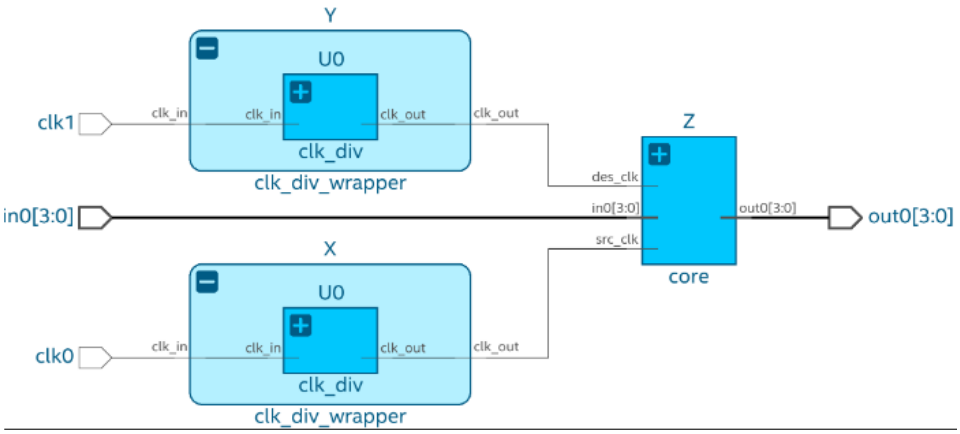
Table 12. Manual Scope of Constraints

Constraint Example	Manual Scope Constraint Interpretation
`set_false_path –from [get_current_instance]|d\` `  –to [get_current_instance]|e`	`set_false_path –from i1|inner|d –to i1|inner|e` `set_false_path –from i2|inner|d –to i2|inner|e` `set_false_path –from i3|d –to i3|e`
`create_generated_clock –divide_by 2 –source \` `  [get_ports inclk] –name \` `  [get_current_instance]_divclk \` `  [get_current_instance]|div` `set_multicycle_path –from [get_current_instance]|a \` `  –to [get_current_instance]|b 2`	`create_generated_clock –divide_by 2 –source \` `  [get_ports inclk] –name “i1_divclk” i1|div` `set_multicycle_path –from i1|a –to i1|b 2 \` `  create_generated_clock –divide_by 2 –source \` `  [get_ports inclk] –name “i2_divclk” i2|div` `set_multicycle_path –from i2|a –to i2|b 2`

2.3.5.2.2. Automatic Scope Entity-bound Constraint Example

In the following design, two instances of the `clk_div` entity are constrained using the entity-bound SDC file approach. After running the Fitter's Plan stage and the timing netlist becomes available, follow the steps below to associate an SDC file with a particular entity in your design:

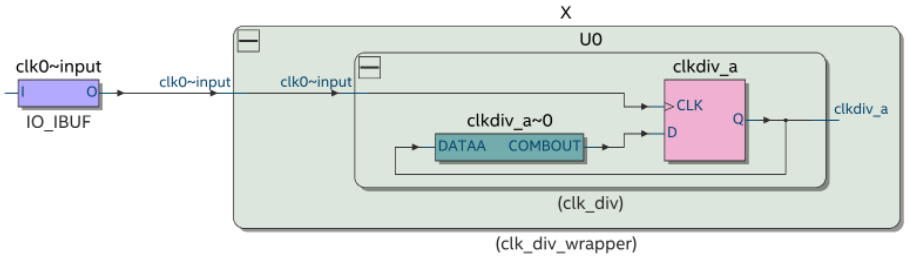
Figure 72. Automatic Scope Example



1. Create a non-entity-bound SDC file that defines constraints targeted by a global scope and add it to the project. For this design, two clocks (`clk0` and `clk1` are defined.

```
# global.sdc
create_clock -period 100MHz -name clk_100 [get_ports clk0]
create_clock -period 75MHz -name clk_75 [get_ports clk1]
```

2. Create a second SDC file to constrain your target entity and add it to the project. This file follows the entity-bound approach and associates with the `clk_div` entity. Consequently, you define constraints as if this entity were at the top-level hierarchy, with path names relative to the entity. For example, the `get_pins clkdiv_a|q` command does not require the `X|U0` hierarchy. In this example, the `get_current_instance` Tcl command generates a unique name for each clock.



In this specific case, the `.sdc` file creates a new clock on the output of the module, and the `get_current_instance` Tcl command generates a unique name for each clock.

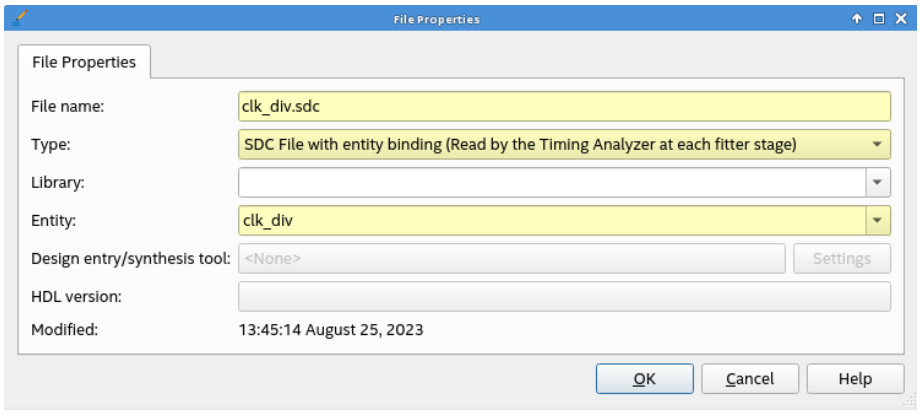
```
# clk_div.sdc
set unique_clock_name "[get_current_instance]_clkout"
create_generated_clock -divide_by 2 -source [get_pins clkdiv_a|clk] -name
$unique_clock_name [get_pins clkdiv_a|q]
```

3. Open the **File Properties** dialog for the `.sdc` file associated with the `clk_div` entity from the files list in the left-hand **Project Tasks** pane.
   a. Select the **SDC File with entity binding (Read by the Timing Analyzer at each fitter stage)** option in the **Type** list.
   b. In the **Entity** list, select **`clk_div`**.

      This step applies automatic scoping to the entity-bound file, where all paths in filter commands are prepended with the top-level path of the current hierarchy. For instance, the command `get_registers clkdiv_a` is dynamically transformed into its fully hierarchical counterpart, such as `get_registers X|U0|clkdiv_a`.

      Note: You must first complete Analysis & Synthesis to populate the list of entities.

Figure 73. File Properties Dialog



Alternatively, you can use the following `.qsf` assignment to set the entity binding:

```
set_global_assignment -name SDC_ENTITY_FILE clk_div.sdc -entity clk_div
```

4. Recompile the project to apply the changes. This results in the corresponding `.sdc` file being effectively bound to the entity in the automatic scope mode.
5. Verify the implementation of the entity-bound property by reviewing the **SDC File List** report in the Timing Analyzer. This report provides a comprehensive list of the applied SDC files for the design. For entity-bound SDC files, the report includes the associated instance, entity name, library, and the status of automatic scoping:

Figure 74. SDC File List Report in the Timing Analyzer

	SDC File Path	Instance	Entity	Library	Promoted	Status	Read at	Processing Time	SDC on RTL
1	main.sdc				No	OK	Fri Aug 25 18:30:09 2023	00:00:00	No
2	clk_div.sdc	X|U0	clk_div	altera_work	Yes	OK	Fri Aug 25 18:30:09 2023	00:00:00	No
3	clk_div.sdc	Y|U0	clk_div	altera_work	Yes	OK	Fri Aug 25 18:30:09 2023	00:00:00	No

6. Determine the correct application of each constraint according to the intended purpose. For example, examine the generated clocks and cross-reference with the clock hierarchy to determine if the constraints are successfully applied, as shown in the following images:

Figure 75. Create Generated Clock Window in the Timing Analyzer

	SDC Command	Name	Source	Master Clock	Targets	Location
1	create_generated_clock	X|U0_clkout	[get_pins {X|U0|clkdiv_a|clk}]	clk_100	[get_pins {X|U0|clkdiv_a|q}]	clk_div.sdc:2
2	create_generated_clock	Y|U0_clkout	[get_pins {Y|U0|clkdiv_a|clk}]	clk_75	[get_pins {Y|U0|clkdiv_a|q}]	clk_div.sdc:2

Figure 76. Clock Hierarchy Summary Window in the Timing Analyzer

	Clock Name	Type	Master	Source	Targets	Period	Frequency	Rise	Fall
1	clk_75	Base			{ clk1 }	13.333	75.0 MHz	0.000	6.666
1	Y|U0_clkout	Generated	clk_75	Y|U0|clkdiv_a|clk	{ Y|U0|clkdiv_a|q }	26.666	37.5 MHz	0.000	13.333
2	clk_100	Base			{ clk0 }	10.000	100.0 MHz	0.000	5.000
1	X|U0_clkout	Generated	clk_100	X|U0|clkdiv_a|clk	{ X|U0|clkdiv_a|q }	20.000	50.0 MHz	0.000	10.000

2.3.5.2.3. Manual Scope Entity-bound Constraint Example

To modify the scope of the entity-bound SDC file to manual, for example, to target elements outside the entity, utilize `.qsf` assignments. By including the `-no_sdc_promotion` parameter in the entity-bound SDC file definition, you can prevent the Compiler from prepending each collection filter with the full path of the current instance. For example, to change to manual scope, the `.sdc` file associated with the `clk_div` entity in the automatic scope example above, add the `-no_sdc_promotion` parameter as follows:

```
set_global_assignment -name SDC_ENTITY_FILE clk_div.sdc -entity clk_div -
no_sdc_promotion
```

To scope your collection filters precisely, use the `get_current_instance` command. By specifying the top-level path to the present instance, `get_current_instance` streamlines the process of scoping filters directed towards elements confined within instance boundaries.

```
# clk_div.sdc
set current_entity_instance [get_current_instance]
set unique_clock_name "${current_entity_instance}_clkout"
create_generated_clock -divide_by 2 -source [get_pins clkdiv_a|clk] \
-name $unique_clock_name [get_pins ${current_entity_instance}|clkdiv_a|q]
```

If you disable the automatic scope for a designated entity-bound SDC file, the **SDC File List** report within the Timing Analyzer indicates this change by displaying "No" in the promoted column:

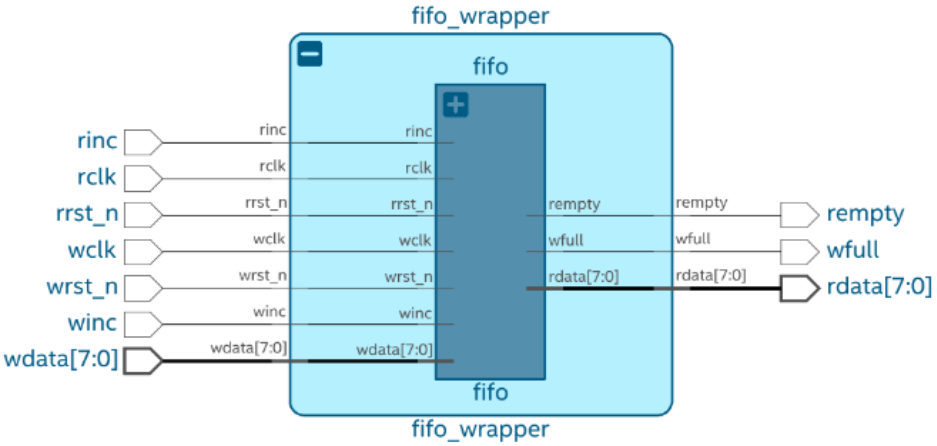
Figure 77. SDC File List Report in the Timing Analyzer

	SDC File Path	Instance	Entity	Library	Promoted	Status	Read at	Processing Time	SDC on RTL
1	main.sdc				No	OK	Fri Aug 25 17:40:25 2023	00:00:00	No
2	clk_div.sdc	X|U0	clk_div	altera_work	No	OK	Fri Aug 25 17:40:25 2023	00:00:00	No
3	clk_div.sdc	Y|U0	clk_div	altera_work	No	OK	Fri Aug 25 17:40:25 2023	00:00:00	No

2.3.5.2.4. Exporting a Design Partition with Entity-bound Constraints

The following example illustrates exporting a partition that includes entity bound constraints for use in another project. This example uses the `fifo` entity.

Figure 78. Entity-Bound Constraints Design Example



Perform these steps to export a design partition with entity-bound constraints:

1. After applying the constraints to the `fifo` entity, click **Fitter** on the Compilation Dashboard to run the Fitter. The Messages window report when the Fitter is complete.
2. Click **Assignments ➤ Design Partitions Window** and define **Default Type** design partition for the `fifo` entity in the **Assignments View** tab of the **Design Partition** dialog box.

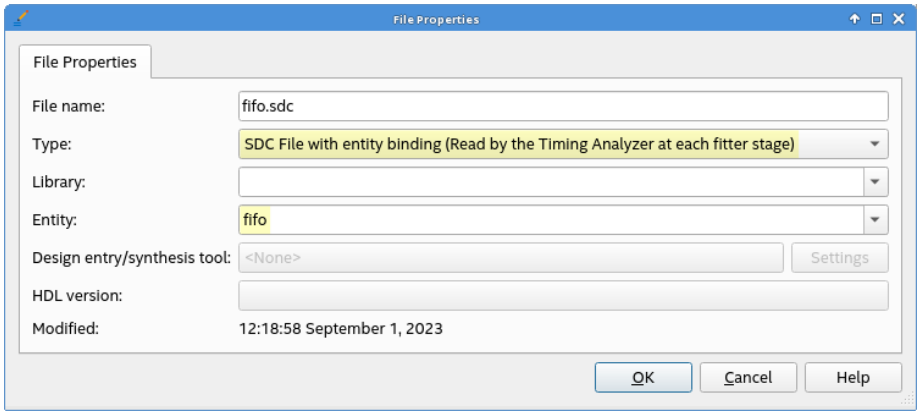
Figure 79. Assignments View of the Design Partition Window

Assignments View | Compilation View

Partition Name	Hierarchy Path	Type	Preservation Level	Empty	Partition Database File
<<new>>					
root_partition	|				
fifo	fifo_wrapper|fifo	Default	Not Set	No	

3. Specify the entity-bound SDC **File name** and **Type** to establish the binding between the `fifo` entity and the `.sdc` file.

Figure 80. File Properties Dialog



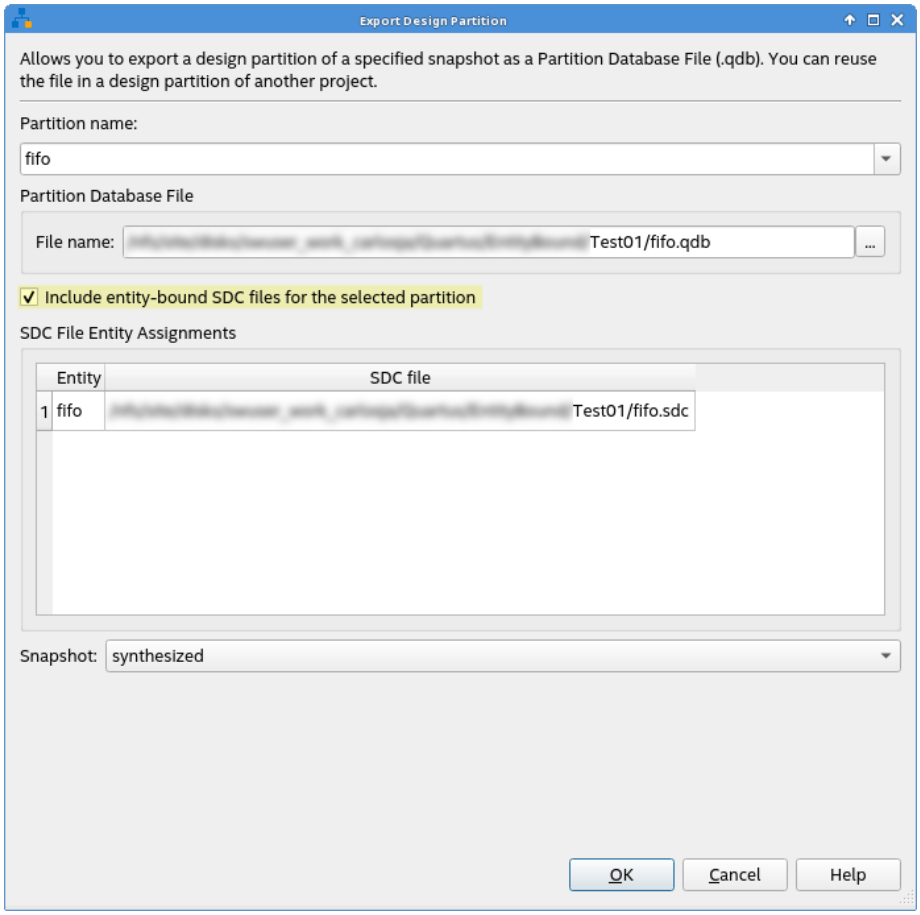
4. Click **Compile Design** on the Compilation Dashboard to run a full compilation and apply the changes to your project. The Timing Analyzer opens by default following a successful full compilation.
5. Confirm the correct association of the `.sdc` file with the `fifo` entity by reviewing the **SDC File List** report in the Timing Analyzer.

Figure 81. SDC File List Report in the Timing Analyzer

	SDC File Path	Instance	Entity	Library	Promoted	Status	Read at	Processing Time	SDC on RTL
1	global.sdc				No	OK	Mon Sep 4 11:34:46 2023	00:00:00	No
2	fifo.sdc	fifo_wrapper|fifo	fifo	altera_work	Yes	OK	Mon Sep 4 11:34:46 2023	00:00:00	No

6. Click **Project ➤ Export Design Partition** and specify the following options:
   a. In the **Partition name** list, select the partition to export.
   b. In **Partition Database File**, specify the partition database file.
   c. Turn on the **Include entity-bound SDC files for the selected partition** option for entity-bound SDC files linked to the chosen partitions.
   d. For **Snapshot**, specify **Synthesized** or **Final**.

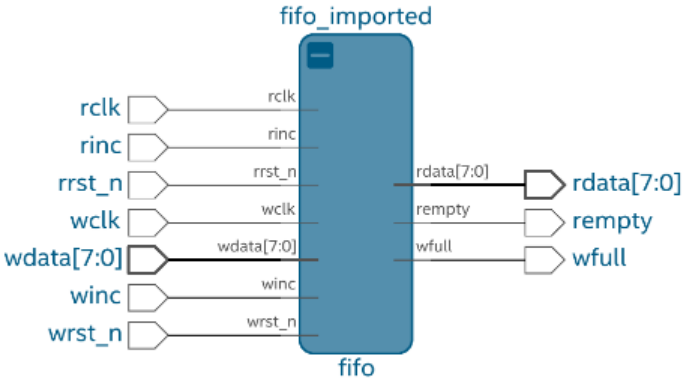
Figure 82. Export Design Partition Dialog



2.3.5.2.5. Importing a Design Partition with Entity-bound Constraints

Importing a partition with entity-bound SDC files requires that you define a black box wrapper for the entity in your design. This wrapper declares a partition in which the data from the imported partition is utilized. Consider the following example with an entity named `fifo_imported`:

Figure 83. Example of an Entity Named `fifo_imported`



To import a design partition with entity-bound constraints, perform these steps:

1. To run design synthesis, click **Analysis & Synthesis** on the Compilation Dashboard.
2. To create a new partition within the wrapper entity, click **Assignments ➤ Design Partitions Window** and specify the following options on the **Assignments View** tab:
   a. Specify the **Partition Name** and the **Hierarchy Path** of the entity instance.
   b. Specify **Default** for the partition **Type**.
   c. Specify **synthesized** in the **Preservation Level** column.
   d. Specify the `.qdb` file from the previous project as the **Partition Database File**

Figure 84. Assignments View of the Design Partition Dialog

Assignments View | Compilation View

Partition Name	Hierarchy Path	Type	Preservation Level	Empty	Partition Database File
<<new>>					
root_partition					
fifo_imported	*fifo_imported*	*Default*	*synthesized*	*No*	*../Test01/fifo.qdb*

3. To run a full compilation, click **Compile Design** on the Compilation Dashboard. The Timing Analyzer appears automatically following successful compilation.
4. Verify the correct application of the entity-bound SDC file assignment in the **SDC File List** report.

Figure 85. SDC File List Report in the Timing Analyzer

	SDC File Path	Instance	Entity	Library	Promoted	Status	Read at	Processing Time	SDC on RTL
1	fifo.sdc	fifo_imported	fifo	altera_work	Yes	OK	Mon Sep 4 11:57:38 2023	00:00:00	No
2	main.sdc				No	OK	Mon Sep 4 11:57:38 2023	00:00:00	No

2.3.6. Constraining Design Partition Ports

You can assign clock definitions and SDC exceptions to design partition ports. The block-based design and partial reconfiguration design flows require the use of design partitions.

The Compiler represents design partition ports in your timing netlist as combinational nodes with persistent names that the Compiler cannot optimize away. You can safely refer to these ports as clock sources or `-through` points in SDC constraints. You can also use design partition port names as `-to` and `-from` points in the `report_path` command.

If a port on `partition_a` has the name `clk_divide`, then the SDC constraint is:

```
create_generated_clock –source clock -divide_by 2 \
     top|partition_a|clk_divide
```

If a set of ports on `partition_b` has the name `data_input[0..7]`, then the SDC constraint is:

```
set_multicycle_path –from top|partition_a|data_reg* \
     -through top|partition_b|data_input* 2
```

You can use multiple `-through` clauses. This technique allows you to specify paths that go through output ports of one design partition, and then through the input ports of another, downstream design partition.

To add constraints to partition ports:

1. Run Analysis & Synthesis or run full compilation on a design containing design partitions.
2. To open the RTL Viewer and locate the partition ports of interest, click **Tools ➤ Netlist Viewers ➤ RTL Viewer**.
3. Using the same names as the **RTL Viewer**, add clock and other SDC constraints to the `.sdc` file for your project. You can use wildcards to refer to more than one port.
4. Recompile the design to apply the new definitions and constraints.

   Aside from block-based and PR flows, this technique also aids in emulation of ASICs using FPGAs. In this type of design, clock networks often span multiple hierarchies of partitions. Typically, designers remove the clock-dividing circuitry from the netlist, since they cannot easily emulate this circuitry on Intel FPGAs. For such clock networks, this technique allows you to define different versions of the clock signal in places where the circuitry is removed.

   You must design and place your partitions strategically, and then define the appropriate ports on these partitions. Ensure that your ports and partitions coincide with the part of the clock network which contains the special circuitry. You can manually edit the emulated ASIC netlist to annotate appropriate clock

definitions and clock relationships. You can also use this technique in any projects where arbitrary locations on paths require constrained timing or defined clock sources.

- Input Constraints (set_input_delay) on page 94

2.3.6.1. Timing Analysis of Imported Compilation Results

You can preserve the compilation results for your design as a version-compatible Quartus database file (`.qdb`) that you can open in a later version of the Quartus Prime software without compatibility issues.

When you import and open the `.qdb` in a later version of software, you can run timing analysis on the imported compilation results without re-running the Compiler.

2.3.7. Using Fitter Overconstraints

Fitter overconstraints are timing constraints that you adjust to overcome modeling inaccuracies, mis-correlation, or other deficiencies in logic optimization. You can overconstrain setup and hold paths in the Fitter to enable more aggressive timing optimization of specific paths.

Overconstraints for Stratix 10 Designs

One typically writes overconstraints that apply only during the Fitter, with a conditional statement that checks the name of the executable that is reading the `.sdc` file. The following example shows a conditional statement that applies an overconstraint during the Fitter.

```
# Example Fitter overconstraint targeting specific nodes
if { $::TimingAnalyzerInfo(nameofexecutable) eq "quartus_fit"} {
  set_max_delay -from ${my_src_regs} -to ${my_dst_regs} 1ns
}
```

One typically applies overconstraints because a particular path (or set of paths) requires more than the default optimization effort from the Fitter. Therefore, overconstraints typically specify particular node or register names in the path or paths that require extra optimization.

For devices that support the Hyperflex® architecture, such as Stratix 10 and Agilex™ FPGA portfolio devices, timing constraints that apply to particular node or register names prevent the Hyper-Retimer from optimizing paths containing those nodes or registers.

Because the Hyper-Retimer is component of the Fitter, an overconstraint that conditionally applies during the Fitter is counter-productive during the Hyper-Retimer portion of the Fitter. The overconstraint actually prevents the optimization instead of focusing the optimization effectively.

When designing for the Hyperflex architecture, use the `is_post_route` Tcl function form of conditional statement to apply the overconstraint during placement and routing but not during the Hyper-Retimer. `is_post_route` allows you to apply

overconstraints and adjust slack for stages of the Fitter, such as Plan, Place, and Route. `is_post_route` also allows post-route retiming via the Hyper-Retimer without affecting sign-off timing analysis.

```
# Example Fitter overconstraint targeting specific nodes (allows for post-route
retiming)
if { ! [is_post_route]} {
  set_max_delay -from ${my_src_regs} -to ${my_dst_regs} 1ns
}
```

Note: The `is_post_route` function is inclusive. To exclude the function, use the negation syntax (`!`).

Overconstraints for Designs that Target All Other Device Families

You can assign Fitter overconstraints that check the name of the current executable, (either `quartus_fit` or `quartus_sta`) to apply different constraints for Fitter optimization and sign-off timing analysis.

```
set fit_flow 0
if { $::TimingAnalyzerInfo(nameofexecutable) == "quartus_fit" } {
   set fit_flow 1
}
if {$fit_flow} {
  # Example Fitter overconstraint targeting specific nodes (restricts retiming)
  set_max_delay -from ${my_src_regs} -to ${my_dst_regs} 1ns
}
```

Other Overconstraint Combinations

You can apply timing constraints to specific stages of the Compiler, in addition to the Fitter as described above. The following table shows different combinations of compile stages and the conditional expression that applies those constraints during the stage or stages.

Table 13. Overconstraint Combinations

Compile Stages	Tcl Condition	Notes
Fitter	`if { $::TimingAnalyzerInfo(nameofexecutable) eq "quartus_fit" }`	Applies constraints during entire Fitter stage. Use for fitter overconstraints with devices that do not support Hyperflex architecture.
Signoff timing	`if { $::TimingAnalyzerInfo(nameofexecutable) eq "quartus_sta" }`	Applies constraints during timing analysis. This condition is uncommon. Typically you apply timing analysis constraints during the entire compile flow.
Plan, Place, and Route	`if { ! [is_post_route] }`	Applies constraints during the Plan, Place, and Route stages in devices that support the Hyperflex architecture. Use for fitter overconstraints .
Retime (HyperRetimer), Finalize, Signoff timing	`if { [is_post_route] }`	Applies constraints after the Route stage completes in devices that support the Hyperflex architecture. This combination of stages is

continued...

Compile Stages	Tcl Condition	Notes
		uncommon. Typically you apply timing analysis constraints during the entire compile flow.
Retime (HyperRetimer) and Finalize	`if { [is_post_route] && $::TimingAnalyzerInfo(nameofexecutable) eq "quartus_fit" }`	Applies constraints during Retiming and Finalize stages in devices that support the Hyperflex architecture. This combination of stages is uncommon.

2.4. Timing Constraint Descriptions

This section provides examples and describes how to correctly apply SDC timing constraints that guide design synthesis, Fitter placement, and produce accurate timing analysis results.
You can define a set of initial timing constraints, and then iteratively modify those constraints as the design progresses.

Early in the design cycle, you can use SDC-on-RTL constraints to target analysis of RTL nodes. This analysis provides a stable reference for constraints that can remain unchanged in subsequent compilation stages, such as clock definitions. Establishing a set of SDC-on-RTL constraints enables their propagation and application throughout the entire design cycle. Concurrently, you can create a conventional `.sdc` file for analysis of the remaining design elements, providing flexibility for iterative constraint adjustments as the design evolves.

This section also outlines the proper application of recommended conventional SDC timing constraints. Conventional SDC constraints guide Fitter placement via `.sdc` files, offering alternative approaches to achieve precise control over constraints throughout the design flow.

2.4.1. Clock Constraints

You must define all clocks and any associated clock characteristics, such as uncertainty, latency or skew. The Timing Analyzer supports `.sdc` commands that accommodate various clocking schemes, such as:

- Base clocks
- Virtual clocks
- Multifrequency clocks
- Generated clocks

You can verify correct implementation of clock constraints by using **Report Clocks** (`report_clocks`) to generate clock timing reports. You can use **Check Timing** (`check_timing`) to report problems with a variety of timing constraints, such as missing clocks.

Related Information

- Report Clocks on page 135
- Check Timing on page 161

2.4.1.1. Creating Base Clocks

Base clocks are the primary input clocks to the device. The **Create Clock** (`create_clock`) constraint allows you to define the properties and requirements for base clocks in the design. Unlike clocks that are generated in the device (such as an on-chip PLL), base clocks are generated by off-chip oscillators or forwarded from an external device. Define base clocks at the top of your `.sdc` file, because generated clocks and other constraints often reference base clocks. The Timing Analyzer ignores any constraints that reference an undefined clock.

The following examples show common use of the `create_clock` constraint:

create_clock Command

The following specifies a 100 MHz requirement on a `clk_sys` input clock port:

```
create_clock -period 100Mhz -name clk_sys [get_ports clk_sys]
```

100 MHz Shifted by 90 Degrees Clock Creation

The following creates a 10 ns clock, with a 50% duty cycle, that is phase shifted by 90 degrees, and applies to port `clk_sys`. This type of clock definition commonly refers to source synchronous, double-rate data that is center-aligned with respect to the clock.

```
create_clock -period 10ns -waveform { 2.5 7.5 } [get_ports clk_sys]
```

Two Oscillators Driving the Same Clock Port

You can apply multiple clocks to the same target with the `-add` option. For example, to specify that you can drive the same clock input at two different frequencies, enter the following commands in your `.sdc` file:

```
create_clock -period 10ns -name clk_100 [get_ports clk_sys]
create_clock -period 5ns -name clk_200 [get_ports clk_sys] -add
```

Although uncommon to define more than two base clocks for a port, you can define as many as are appropriate for your design, making sure you specify `-add` for all clocks after the first.

Creating Multifrequency Clocks

You must create a multifrequency clock if your design has more than one clock source feeding a single clock node. The additional clock may act as a low-power clock, with a lower frequency than the primary clock. If your design uses multifrequency clocks, use the `set_clock_groups` command to define clocks that are physically exclusive (that is, clocks that are not physically present at the same time).

Use the `create_clock` command with the `-add` option to create multiple clocks on a clock node. You can create a 10 ns clock applied to clock port `clk`, and then add an additional 15 ns clock to the same clock port. The Timing Analyzer analyzes both clocks.

```
create_clock –period 10ns –name clock_primary –waveform { 0 5 } \
    [get_ports clk]
create_clock –period 15ns –name clock_secondary –waveform { 0 7.5 } \
    [get_ports clk] -add
```

You can verify correct implementation of clock constraints by using **Report Clocks** (`report_clocks`) to generate clock timing reports. You can use **Check Timing** (`check_timing`) to report problems with a variety of timing constraints, such as missing clocks.

Related Information

- Accounting for Clock Effect Characteristics on page 90
- Report Clocks on page 135
- Check Timing on page 161

2.4.1.1.1. Automatic Clock Detection and Constraint Creation

Use the `derive_clocks` command to automatically create base clocks in your design The `derive_clocks` command is equivalent to using the `create_clock` command for each register or port feeding the clock pin of a register. The `derive_clocks` command creates clock constraints on ports or registers to ensure every register in your design has a clock constraints, and it applies one period to all base clocks in your design.

The following command specifies a base clock with a 100 MHz requirement for unconstrained base clock nodes.

```
derive_clocks -period 10
```

The `derive_clocks` command names the automatically created base clocks according to the name of the register or port that is the target of each clock. Automatically derived clocks have the suffix "~derived". You can choose another suffix to append with the `-suffix` option for the `derive_clocks` command.

Caution: If your design has more than a single clock, the `derive_clocks` command constrains all the clocks to the same specified frequency. To achieve a realistic analysis of your design's timing requirements, do not use `derive_clocks` command for final timing sign-off. Instead, use `create_clock` and `create_generated_clock` commands to make individual clock constraints for all clocks in your design.

If you want to create some base clocks automatically, use the `-create_base_clocks` option to `derive_pll_clocks`. With this option, the `derive_pll_clocks` command automatically creates base clocks for each PLL, based on the input frequency information that you specify when you generate the PLL. This feature works for simple port-to-PLL connections. Base clocks do not automatically generate for complex PLL connectivity, such as cascaded PLLs. You can also use the command `derive_pll_clocks -create_base_clocks` to create the input clocks for all PLL inputs automatically.

2.4.1.2. Creating Virtual Clocks

A virtual clock is a clock without a real source in the design, or a clock that does not interact directly with the design. You can use virtual clocks in I/O constraints to represent clocks that drive external devices connected to the FPGA..

To create virtual clocks, use the `create_clock` constraint with no value for the *<targets>* option.

This following example defines a 100 MHz virtual clock because the command includes no <*targets*>.

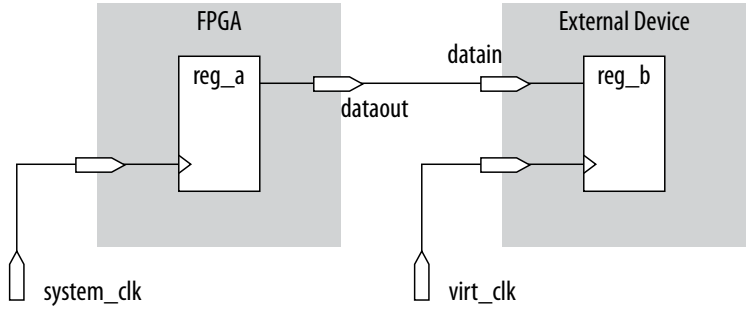
```
create_clock -period 10 -name my_virt_clk
```

I/O Constraints with Virtual Clocks

You can use a base clock to constrain the circuit in the FPGA and a virtual clock to represent the clock driving the external device. .

Figure 86. Virtual Clock Board Topology

The figure shows the base clock (`system_clk`), virtual clock (`virt_clk`), and output delay for the virtual clock constraints example



The following example creates the 10 ns `virt_clk` virtual clock, with a 50% duty cycle, with the first rising edge occurring at 0 ns. The virtual clock can then become the clock source for an output delay constraint.

Example 3. Virtual Clock Constraints

```
#create base clock for the design
create_clock -period 5 [get_ports system_clk]
#create the virtual clock for the external register
create_clock -period 10 -name virt_clk
#set the output delay referencing the virtual clock
set_output_delay -clock virt_clk -max 1.5 [get_ports dataout]
set_output_delay -clock virt_clk -min 0.0 [get_ports dataout]
```

You can verify correct implementation of clock constraints by using **Report Clocks** (`report_clocks`) to generate clock timing reports. You can use **Check Timing** (`check_timing`) to report problems with a variety of timing constraints, such as the number of unreferenced virtual clocks without constraint.

Related Information

- Report Clocks on page 135
- Check Timing on page 161

2.4.1.2.1. Specifying I/O Interface Uncertainty

Virtual clocks are recommended for I/O constraints because they most accurately represent the clocking topology of the design. An additional benefit is that you can specify different uncertainty values on clocks that interface with external I/O ports and clocks that feed register-to-register paths inside the FPGA.

2.4.1.2.2. I/O Interface Clock Uncertainty Example

To specify I/O interface uncertainty, you must create a virtual clock and constrain the input and output ports with the `set_input_delay` and `set_output_delay` commands that reference the virtual clock.

When the `set_input_delay` or `set_output_delay` commands reference a clock port or PLL output, the virtual clock allows the `derive_clock_uncertainty` command to apply separate clock uncertainties for internal clock transfers and I/O interface clock transfers.

Create the virtual clock with the same properties as the original clock that is driving the I/O port, as the following example shows:

Example 4. SDC Commands to Constrain the I/O Interface

```
# Create the base clock for the clock port
create_clock -period 10 -name clk_in [get_ports clk_in]
# Create a virtual clock with the same properties of the base clock
# driving the source register
create_clock -period 10 -name virt_clk_in
# Create the input delay referencing the virtual clock and not the base
# clock
# DO NOT use set_input_delay -clock clk_in <delay value>
# [get_ports data_in]
set_input_delay -clock virt_clk_in <delay value> [get_ports data_in]
```

2.4.1.3. Creating Generated Clocks (create_generated_clock)

The **Create Generate Clock** (`create_generated_clock`) constraint allows you to define the properties and constraints of an internally generated clock in the design. You specify the **Clock name** (`-name`), the **Source** node (`-source`) from which clock derives, and the **Relationship to the source** properties. Define generated clocks for any node that modifies the properties of a clock signal, including modifying the phase, frequency, offset, or duty cycle.

You apply generated clocks most commonly on the outputs of PLLs, on register clock dividers, clock muxes, and clocks forwarded to other devices from an FPGA output port, such as source synchronous and memory interfaces. In the `.sdc` file, enter generated clocks after the base clocks definitions. Generated clocks automatically account for all clock delays and clock latency to the generated clock target.

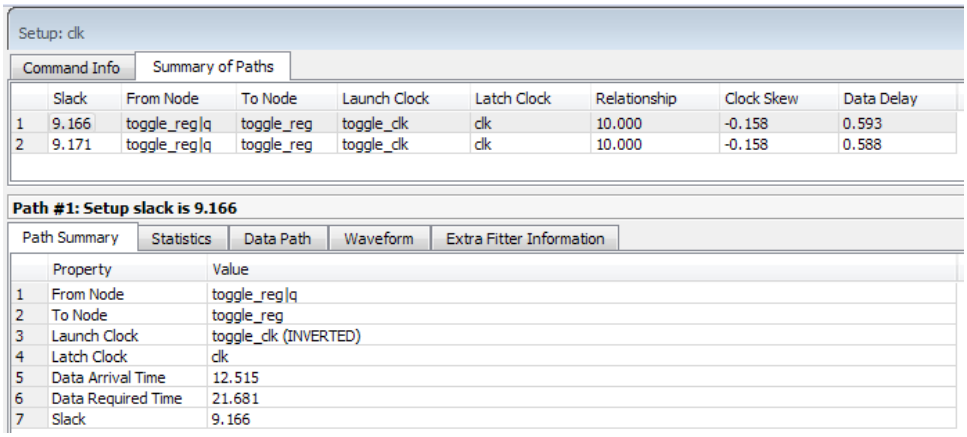
The `-source` option specifies the name of a node in the clock path that you use as reference for your generated clock. The source of the generated clock must be a node in your design netlist, and not the name of a clock you previously define. You can use any node name on the clock path between the input clock pin of the target of the generated clock and the target node of its reference clock as the source node.

Specify the input clock pin of the target node as the source of your new generated clock. By accepting a node as the generated clock's source clock, the generated clock constraint decouples from the source clock. If you change the source clock for the generated clock and the source node is the same, you do not have to edit the generated clock constraint.

If you have multiple base clocks feeding a node that is the source for a generated clock, you must define multiple generated clocks. You associate each generated clock with one base clock using the `-master_clock` option in each generated clock statement. In some cases, generated clocks generate with combinational logic.

Depending on how your clock-modifying logic synthesizes, the source or target node can change from one compilation to the next. If the name changes after you write the generated clock constraint, the Compiler ignores the generated clock because that target name no longer exists in the design. To avoid this problem, use a synthesis attribute or synthesis assignment to retain the final combinational node name of the clock-modifying logic. Then use the kept name in your generated clock constraint.

Figure 87. Example of clock-as-data



When you create a generated clock on a node that ultimately feeds the data input of a register, this creates a special case of "clock-as-data." The Timing Analyzer treats clock-as-data differently. For example, if you use clock-as-data with DDR, you must consider both the rise and the fall of this clock, and the Timing Analyzer reports both rise and fall. With clock-as-data, the Compiler treats the **From Node** as the target of the generated clock, and the **Launch Clock** as the generated clock.

In Example of clock-as-data, the first path is from `toggle_clk (INVERTED)` to `clk`, and the second path is from `toggle_clk` to `clk`. The slack in both cases is slightly different due to the difference in rise and fall times along the path. The **Data Delay** column reports the ~5 ps difference. Only the path with the lowest slack value requires consideration. The Timing Analyzer only reports the worst-case path between the two (rise and fall). In this example, if you do not define the generated clock on the register output, then timing analysis reports only one path with the lowest slack value.

You can use the `derive_pll_clocks` command to automatically generate clocks for all PLL clock outputs. The properties of the generated clocks on the PLL outputs match the properties you define for the PLL.

You can verify correct implementation of clock constraints by using **Report Clocks** (`report_clocks`) to generate clock timing reports. You can use **Check Timing** (`check_timing`) to report problems with a variety of timing constraints, such as the number of generated clocks that are invalid.

- derive_pll_clocks

2.4.1.3.1. Clock Divider Example (-divide_by)

A common form of generated clock is the divide-by-two register clock divider. The following example constraint creates a half-rate clock on the divide-by-two register.

```
create_clock -period 10ns -name clk_sys [get_ports clk_sys]
create_generated_clock -name clk_div_2 -divide_by 2 -source \
    [get_ports clk_sys] [get_pins reg|q]
```

To specify the clock pin of the register as the clock source:

```
create_clock -period 10ns -name clk_sys [get_ports clk_sys]
create_generated_clock -name clk_div_2 -divide_by 2 -source \
    [get_pins reg|clk] [get_pins reg|q]
```

Figure 88. Clock Divider

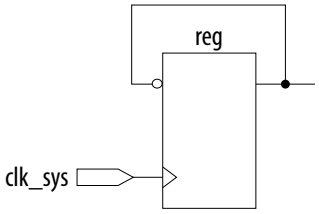

Figure 89. Clock Divider Waveform

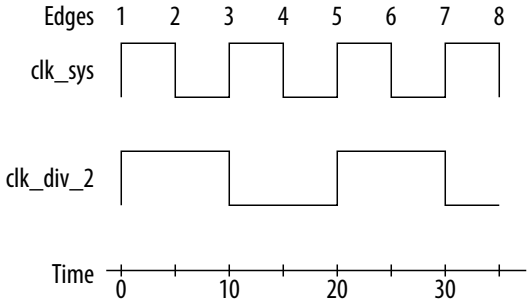
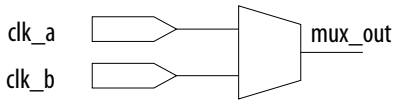


2.4.1.3.2. Clock Multiplexer Example

The output of a clock multiplexer (mux) is a form of generated clock. Each input clock requires one generated clock on the output. The following `.sdc` example also includes the `set_clock_groups` command to indicate that the two generated clocks can never be active simultaneously in the design. Therefore, the Timing Analyzer does not analyze cross-domain paths between the generated clocks on the output of the clock mux.

Figure 90. Clock Mux



```
create_clock -name clock_a -period 10 [get_ports clk_a]
create_clock -name clock_b -period 10 [get_ports clk_b]
create_generated_clock -name clock_a_mux -source [get_ports clk_a] \
```

```
    [get_pins clk_mux|mux_out]
create_generated_clock -name clock_b_mux -source [get_ports clk_b] \
    [get_pins clk_mux|mux_out] -add
set_clock_groups -logically_exclusive -group clock_a_mux -group clock_b_mux
```

2.4.1.4. Deriving PLL Clocks

The **Derive PLL Clocks** (`derive_pll_clocks`) constraint automatically creates clocks for each output of any PLL in your design. `derive_pll_clocks` detects your current PLL settings and automatically creates generated clocks on the outputs of every PLL by calling the `create_generated_clock` command.

Note: Only Arria 10 and Cyclone 10 GX devices support the **Derive PLL Clocks** (`derive_pll_clocks`) constraint. For all other supported devices, the Timing Analyzer automatically derives PLL clocks from constraints bound to the related IP.

Create Base Clock for PLL input Clock Ports

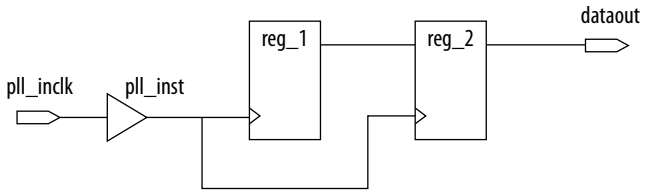
If your design contains transceivers, LVDS transmitters, or LVDS receivers, use the `derive_pll_clocks` to constrain this logic in your design and create timing exceptions for those blocks.

```
create_clock -period 10.0 -name fpga_sys_clk [get_ports fpga_sys_clk]
derive_pll_clocks
```

Include the `derive_pll_clocks` command in your `.sdc` file after any `create_clock` command. Each time the Timing Analyzer reads the `.sdc` file, the appropriate generated clock is created for each PLL output clock pin. If a clock exists on a PLL output before running `derive_pll_clocks`, the pre-existing clock has precedence, and an auto-generated clock is not created for that PLL output.

The following shows a simple PLL design with a register-to-register path:

Figure 91. Simple PLL Design



The Timing Analyzer generates messages like the following example when you use the `derive_pll_clocks` command to constrain the PLL.

Example 5. derive_pll_clocks Command Messages

```
Info:
Info: Deriving PLL Clocks:
Info: create_generated_clock -source pll_inst|altpll_component|pll|inclk[0] -
divide_by 2 -name
pll_inst|altpll_component|pll|clk[0] pll_inst|altpll_component|pll|clk[0]
Info:
```

The input clock pin of the PLL is the node `pll_inst|altpll_component|pll|inclk[0]` which is the `-source` option. The name of the output clock of the PLL is the PLL output clock node, `pll_inst|altpll_component|pll|clk[0]`.

If the PLL is in clock switchover mode, multiple clocks generate for the output clock of the PLL; one for the primary input clock (for example, `inclk[0]`), and one for the secondary input clock (for example, `inclk[1]`). Create exclusive clock groups for the primary and secondary output clocks since they are not active simultaneously.

You can verify correct implementation of clock constraints by using **Report Clocks** (`report_clocks`) to generate clock timing reports. You can use **Check Timing** (`check_timing`) to report problems with a variety of timing constraints, such as the number of instances where clocks that are assigned to a PLL do not correspond properly with the PLL settings you define in design files.

- Check Timing on page 161

2.4.1.5. Creating Clock Groups (set_clock_groups)

The **Set Clock Groups** (`set_clock_groups`) constraint allows you to specify which clocks in the design are unrelated.

The `set_clock_groups` command allows you to cut timing between unrelated clocks in different groups. The Timing Analyzer performs the same analysis regardless of whether you specify `-exclusive` or `-asynchronous` groups. You define a clock group with the `-group` option. The Timing Analyzer excludes the timing paths between clocks for each of the separate groups.

The following tables show the impact of `set_clock_groups`.

Table 14. set_clock_groups -group A

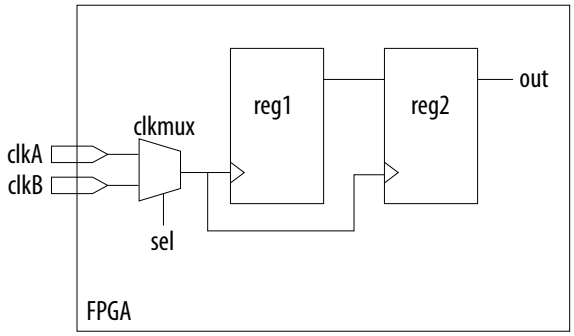
2.4.1.5.1. Exclusive Clock Groups (-logically_exclusive or -physically_exclusive)

You can use the `logically_exclusive` option to declare that two clocks are physically active simultaneously, but the two clocks are not actively used at the same time (that is, the clocks are logically mutually exclusive). The `physically_exclusive` option declares clocks that cannot be physically on the device at the same time.

If you define multiple clocks for the same node, you can use clock group assignments with the `logically_exclusive` option to declare clocks as mutually exclusive. This technique can be useful for multiplexed clocks.

For example, consider an input port that is clocked by either a 100-MHz or 125-MHz clock. You can use the `logically_exclusive` option to declare that the clocks are mutually exclusive and eliminate clock transfers between the 100-MHz and 125-MHz clocks, as the following diagrams and example SDC constraints show:

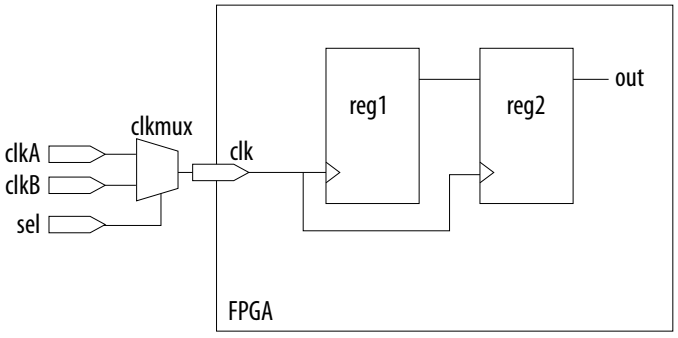
Figure 92. Synchronous Path with Clock Mux Internal to FPGA



Example SDC Constraints for Internal Clock Mux

```
# Create a clock on each port
create_clock -name clk_100 -period 10 [get_ports clkA]
create_clock -name clk_125 -period 8 [get_ports clkB]
# Create derived clocks on the output of the mux
create_generated_clock -name mux_100 -source [get_ports clkA] \
     [get_pins clkmux|combout]
create_generated_clock -name mux_125 -source [get_ports clkB] \
     [get_pins clkmux|combout] -add
# Set the two clocks as exclusive clocks
set_clock_groups -logically_exclusive -group {mux_100} -group {mux_125}
```

Figure 93. Synchronous Path with Clock Mux External to FPGA



Example SDC Constraints for External Clock Mux

```
# Create virtual clocks for the external primary clocks
create_clock -period 10 -name clkA
create_clock -period 20 -name clkB
# Create derived clocks on the port clk
create_generated_clock -name mux_100 -master_clock clkA [get_ports clk]
create_generated_clock -name mux_125 -master_clock clkB [get_ports clk] -add
# Assume no clock network latency between the external clock sources & the \
     clock mux output
set_clock_latency -source 0 [get_clocks {mux_100 mux_125}]
# Set the two clocks as exclusive clocks
set_clock_groups -physically_exclusive -group mux_100 -group mux_125
```

2.4.1.5.2. Asynchronous Clock Groups (-asynchronous)

Use the `-asynchronous` option to create asynchronous clock groups. You can use asynchronous clock groups to break the timing relationship when data transfers through a FIFO between clocks running at different rates.

2.4.1.5.3. set_clock_groups Constraint Tips

When you use `derive_pll_clocks` to create clocks, it can be time consuming to determine all the clock names to include in `set_clock_groups` constraints. However, you can use the following technique to somewhat automate clock constraint creation, even if you do not know all of the clock names.

1. Create a basic `.sdc` file that contains the Recommended Initial Conventional SDC Constraints, except omit the `set_clock_groups` constraint for now.
2. To add the `.sdc` to the project, click **Assignments ➤ Settings ➤ Timing Analyzer**. Specify the `.sdc` file under **SDC files to include in the project**.
3. To open the Timing Analyzer, click **Tools ➤ Timing Analyzer**.
4. In the **Task** pane, double-click **Report Clocks**. The Timing Analyzer reads your `.sdc`, applies the constraints (including `derive_pll_clocks`), and reports all the clocks.
5. From the Clocks Summary report, copy all the clock names that appear in the first column. The report lists the clock names in the correct format for recognition in the Timing Analyzer.
6. Open .sdc file and the paste the clock names into the file, one clock name per line.
7. Format the list of clock names list into the `set_clock_groups` command by cutting and pasting clock names into appropriate groups. Next, paste the following template into the `.sdc` file:

```
set_clock_groups -asynchronous -group { \
} \
 -group { \
} \
-group  { \
} \
-group { \
}
```

8. Cut and paste the clock names into groups to define their relationship, adding or removing groups, as necessary. Format the groups to make the code readable.

   Note: This command can be difficult to read on a single line. You can use the Tcl line continuation character "\" to make this more readable. Place a space after the last character, and then place the "\" character at the end of the line. Be careful not to include any spaces after the escape character. Otherwise, the space becomes the escape character, rather than the end-of-line character.

```
set_clock_groups -asynchronous \
    -group {adc_clk \
       the_adc_pll|altpll_component_autogenerated|pll|clk[0] \
       the_adc_pll|altpll_component_autogenerated|pll|clk[1] \
       the_adc_pll|altpll_component_autogenerated|pll|clk[2] \
    } \
    -group {sys_clk \
       the_system_pll|altpll_component_autogenerated|pll|clk[0] \
       the_system_pll|altpll_component_autogenerated|pll|clk[1] \
```

```
    } \
    -group {the_system_pll|altpll_component_autogenerated|pll|clk[2] \
    }
```

Note: The last group has a PLL output `system_pll|..|clk[2]` while the input clock and other PLL outputs are in different groups. If you use PLLs, and the input clock frequency does not relate to the frequency of the PLL's outputs, you must treat the PLLs asynchronously. Typically the outputs of a PLL are related and are in the same group, but this is not a requirement.

For designs with complex clocking, creating clock groups can be an iterative process. For example, a design with two DDR3 cores and high-speed transceivers can have thirty or more clocks. In such cases, you start by adding the clocks that you manually create. Timing Analyzer assumes that the clocks not appearing in the clock groups command relate to every clock and conservatively groups the known clocks. If the design still has failing paths between unrelated clock domains, you can add the new clock domains, as necessary. In this case, a large number of the clocks are not in the `set_clock_groups` command, because they are either cut in the `.sdc` file for the IP (such as the `.sdc` files that the DDR3 cores generate), or they connect only to related clock domains.

For many designs, that is all that's necessary to constrain the IP.

Multicycle Paths on page 102

2.4.1.6. Accounting for Clock Effect Characteristics

The clocks you create with the Timing Analyzer are ideal clocks that do not account for any board effects. You can account for clock effect characteristics with clock latency and clock uncertainty constraints.

You can verify correct implementation of clock constraints by using **Report Clocks** (`report_clocks`) to generate clock timing reports. You can use **Check Timing** (`check_timing`) to report problems with a variety of timing constraints, such as missing clocks.

Related Information

- Report Clocks on page 135
- Check Timing on page 161

2.4.1.6.1. Set Clock Latency (set_clock_latency)

The **Set Clock Latency** (`set_clock_latency`) constraint allows you to specify additional delay (that is, latency) in a clock network. This delay value represents the external delay from a virtual (or ideal) clock through the longest **Late** (`-late`) or shortest **Early** (`-early`) path, with reference to the **Rise** (`-rise`) or **Fall** (`-fall`) of the clock transition.

When calculating setup analysis, the Timing Analyzer uses the late clock latency for the data arrival path and the early clock latency for the clock arrival path. . When calculating hold analysis, the Timing Analyzer uses the early clock latency for the data arrival time and the late clock latency for the clock arrival time.

There are two forms of clock latency: clock source latency, and clock network latency. Source latency is the propagation delay from the origin of the clock to the clock definition point (for example, a clock port). Network latency is the propagation delay from a clock definition point to a register's clock pin. The total latency at a register's clock pin is the sum of the source and network latencies in the clock path.

To specify source latency to any clock ports in your design, use the `set_clock_latency` command.

Note: The Timing Analyzer automatically computes network latencies. Therefore, you can only characterize source latency with the `set_clock_latency` command using the `-source` option.

Related Information

set_clock_latency Command, Quartus Prime Help

2.4.1.6.2. Clock Uncertainty

By default, the Timing Analyzer creates clocks that are ideal and have perfect edges. To mimic clock-level effects like jitter, you can add uncertainty to those clock edges. The Timing Analyzer automatically calculates appropriate setup and hold uncertainties and applies those uncertainties to all clock transfers in your design, even if you do not include the `derive_clock_uncertainty` command in your `.sdc` file. Setup and hold uncertainties are a critical part of constraining your design correctly.

The Timing Analyzer subtracts setup uncertainty from the data required time for each applicable path and adds the hold uncertainty to the data required time for each applicable path. This slightly reduces the setup and hold slack on each path.

The Timing Analyzer accounts for uncertainty clock effects for three types of clock-to-clock transfers: intraclock transfers, interclock transfers, and I/O interface clock transfers.

- Intraclock transfers occur when the register-to-register transfer takes place in the device and the source and destination clocks come from the same PLL output pin or clock port.
- Interclock transfers occur when a register-to-register transfer takes place in the core of the device and the source and destination clocks come from a different PLL output pin or clock port.
- I/O interface clock transfers occur when data transfers from an I/O port to the core of the device or from the core of the device to the I/O port.

To manually specify clock uncertainty, use the `set_clock_uncertainty` command. You can specify the uncertainty separately for setup and hold. You can also specify separate values for rising and falling clock transitions. You can override the value that the `derive_clock_uncertainty` command automatically applies.

The `derive_clock_uncertainty` command accounts for PLL clock jitter, if the clock jitter on the input to a PLL is within the input jitter specification for PLL's in the target device. If the input clock jitter for the PLL exceeds the specification, add additional uncertainty to your PLL output clocks to account for excess jitter with the `set_clock_uncertainty -add` command. Refer to the device handbook for your device for jitter specifications.

You can also use `set_clock_uncertainty -add` to account for peak-to-peak jitter from a board when the jitter exceeds the jitter specification for that device. In this case you add uncertainty to both setup and hold equal to 1/2 the jitter value:

```
set_clock_uncertainty –setup –to <clock name>  \
    -setup –add <p2p jitter/2>
```

```
set_clock_uncertainty –hold –enable_same_physical_edge –to <clock name> \
    –add <p2p jitter/2>
```

There is a complex set of precedence rules for how the Timing Analyzer applies values from `derive_clock_uncertainty` and `set_clock_uncertainty`, which depend on the order of commands and options in your `.sdc` files. The Help topics below contain complete descriptions of these rules. These precedence rules are easier to implement if you follow these recommendations:

- To assign your own clock uncertainty values to any clock transfers, put your `set_clock_uncertainty` exceptions after the `derive_clock_uncertainty` command in the `.sdc` file.
- When you use the `-add` option for `set_clock_uncertainty`, the value you specify is additive to the `derive_clock_uncertainty` value. If you do not specify `-add`, the value you specify replaces the value from `derive_clock_uncertainty`.

2.4.1.7. Constraining CDC Paths

It is essential to apply timing constraints to the multibit clock domain crossing (CDC) paths in your design. You can use the following constraints to constrain CDC paths:

Attention: As of Quartus Prime Pro Edition software version 21.3, the `set_false_path` constraint does not override the `set_max_skew` constraint. You can now apply the `set_false_path` and `set_max_skew` constraints on the same path without override.

Table 19. CDC Path Constraints

Constraints	Description
`set_false_path` `set_clock_groups -asynchronous`	Both constraints prevent the Compiler from optimizing slack between asynchronous domain crossings. `set_clock_groups` is the most aggressive constraint. • Clock-based false paths are less aggressive because these constraints only cut timing on the `from_clock` to `to_clock` order specified. • Clock-based false paths are unlike clock groups that cut the path in both directions. • Path-based false paths are the most specific constraint because they cut only on the specified `from` and `to` nodes.
`set_max_skew`	Sets a bound on the allowable skew between different bus bits.

continued...

Constraints	Description
	• Check the timing of your clock domain crossing by running the **Report Max Skew Summary** command. • The actual skew requirements depends on your design characteristics, and how you handle the clock domain crossing.
`set_net_delay -max` `set_data_delay`	Sets a bound on the allowable datapath delay on any bit of a bus transfer. • `set_net_delay` is for constraining individual clock edges and nets. Run the **Report Net Delay Summary** command to report data for this constraint. • `set_data_delay` is for constraining entire paths. Run the **Report Data Delay** command to report data for this constraint.

The following shows example constraints for a clock domain crossing between `data_a` in clock domain `clk_a`, and `data_b` in clock domain `clk_b`:

```
create_clock -name clk_a -period 4.000 [get_ports {clk_a}]
create_clock -name clk_b -period 4.500 [get_ports {clk_b}]
set_clock_groups -asynchronous -group [get_clocks {clk_a}] -group \
     [get_clocks {clk_b}]
set_net_delay -from [get_registers {data_a[*]}] -to [get_registers \
     {data_b[*]}] -max -get_value_from_clock_period \
     dst_clock_period -value_multiplier 0.8
set_max_skew -from [get_keepers {data_a[*]}] -to [get_keepers \
     {data_b[*]}] -get_skew_value_from_clock_period min_clock_period \
     -skew_value_multiplier 0.8
```

The following examples show applying `set_false_path` for a design that contains a DCFIFO block to avoid timing failures in the synchronization registers. These examples are for constraining single-bit synchronizer CDC paths:

- For paths crossing from the write into the read domain, apply a false path assignment between registers `delayed_wrptr_g` and `rs_dgwp`:

```
set_false_path -from [get_registers {*dcfifo*delayed_wrptr_g[*]}] \
-to [get_registers {*dcfifo*rs_dgwp*}]
```

- For paths crossing from the read into the write domain, apply a false path assignment between registers `rdptr_g` and `ws_dgrp`:

```
set_false_path -from [get_registers {*dcfifo*rdptr_g[*]}] \
-to [get_registers {*dcfifo*ws_dgrp*}]
```

You can verify correct implementation of clock constraints in the following CDC related reports:

Related Information

- Report Clock Transfers on page 137
- Report CDC Viewer on page 139
- Report Asynchronous CDC on page 142

2.4.2. I/O Constraints

The Timing Analyzer reviews setup and hold relationships for designs in which an external source interacts with a register internal to the design. The Timing Analyzer supports input and output external delay modeling with the `set_input_delay` and `set_output_delay` commands. You can specify the clock and minimum and maximum arrival times relative to the clock.

Specify internal and external timing requirements before you fully analyze a design. With external timing requirements specified, the Timing Analyzer verifies the I/O interface, or periphery of the device, against any system specification.

You can use the **Check Timing** (`check_timing`) command to report problems with a variety of timing constraints, such as the number of input ports that are not clocks that have no input delay constraint.

Related Information

Check Timing on page 161

2.4.2.1. Input Constraints (set_input_delay)

Input constraints specify delays for all external signals feeding the FPGA. Specify input requirements for all input ports in your design.

```
set_input_delay -clock { clock } -clock_fall -fall -max 20 foo
```

Use the **Set Input Delay** (`set_input_delay`) constraint to specify external input delay requirements. Specify the **Clock name** (`-clock`) to reference the virtual or actual clock. You can specify a clock to allow the Timing Analyzer to correctly derive clock uncertainties for interclock and intraclock transfers. The clock defines the launching clock for the input port. The Timing Analyzer automatically determines the latching clock inside the device that captures the input data, because all clocks in the device are defined.

Figure 94. Input Delay Diagram

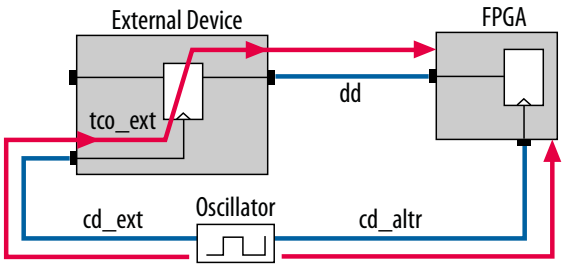

Figure 95. Input Delay Calculation

$$\text{input delay}_{MAX} = (\text{cd\_ext}_{MAX} - \text{cd\_altr}_{MIN}) + \text{tco\_ext}_{MAX} + \text{dd}_{MAX}$$
$$\text{input delay}_{MIN} = (\text{cd\_ext}_{MIN} - \text{cd\_altr}_{MAX}) + \text{tco\_ext}_{MIN} + \text{dd}_{MIN}$$

If your design includes partition boundary ports, you can use the `-blackbox` option with `set_input_delay` to assign input delays. The `-blackbox` option creates a new keeper timing node with the same name as the boundary port. This new node permits the propagation of timing paths through the original boundary port and acts as a `set_input_delay` constraint. The new keeper timing nodes display when you use the `get_keepers` command. You can remove these black box constraints with `remove_input_delay -blackbox`.

You can use the **Check Timing** (`check_timing`) command to report problems with a variety of timing constraints, such as the number of input ports that are not clocks that have no input delay constraint.

Related Information

Check Timing on page 161

2.4.2.2. Output Constraints (set_output_delay)

Output constraints specify all external delays from the device for all output ports in your design.

```
set_output_delay -clock { clock } -clock_fall -rise -max 2 foo
```

Use the **Set Output Delay** (`set_output_delay`) constraint to specify external output delay requirements. Specify the **Clock name** (`-clock`) to reference the virtual or actual clock. When specifying a clock, the clock defines the latching clock for the output port. The Timing Analyzer automatically determines the launching clock inside the device that launches the output data, because all clocks in the device are defined. The following figure is an example of an output delay referencing a virtual clock.

Figure 96. Output Delay Diagram

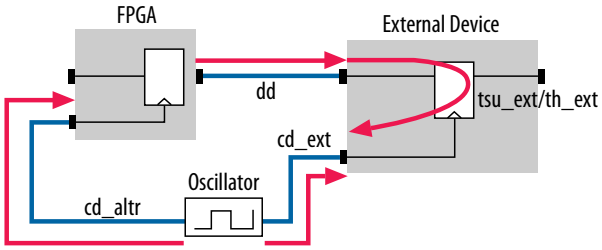

Figure 97. Output Delay Calculation

$$\text{output delay}_{MAX} = \text{dd}_{MAX} + \text{tsu\_ext} + (\text{cd\_altr}_{MAX} - \text{cd\_ext}_{MIN})$$
$$\text{output delay}_{MIN} = (\text{dd}_{MIN} - \text{th\_ext} + (\text{cd\_altr}_{MIN} - \text{cd\_ext}_{MAX}))$$

If your design includes partition boundary ports, you can use the `-blackbox` option with `set_ouput_delay` to assign output delays. The `-blackbox` option creates a new keeper timing node with the same name as the boundary port. This new node permits the propagation of timing paths through the original boundary port and acts as a `set_output_delay` constraint. The new keeper timing nodes display when you use the `get_keepers` command.

You can remove blackbox constraints with `remove_output_delay -blackbox`.

You can use the **Check Timing** (`check_timing`) command to report problems with a variety of timing constraints, such as the number of output ports that have no output delay constraint.

2.4.3. Delay and Skew Constraints

You can specify skew and delays to model external device timing and board timing parameters.

2.4.3.1. Advanced I/O Timing and Board Trace Model Delay

The Timing Analyzer can use advanced I/O timing and board trace model constraints to model I/O buffer delays in your design.

If you change any advanced I/O timing settings or board trace model assignments, recompile your design before you analyze timing, or use the `-force_dat` option to force delay annotation when you create a timing netlist.

Example 6. Forcing Delay Annotation

```
create_timing_netlist -force_dat
```

2.4.3.2. Maximum Skew (set_max_skew)

The **Set Max Skew** (`set_max_skew`) constraint specifies the maximum allowable skew between the sets of registers or ports you specify. In order to constrain skew across multiple paths, you must constrain all such paths within a single `set_max_skew` constraint.

```
set_max_skew -from_clock { clock } -to_clock { * } -from foo -to blat 2
```

The `set_max_delay`, `set_min_delay`, `set_multicycle_path`, and `set_false_path` constraints do not affect the `set_max_skew` timing constraint. However, the `set_clock_groups` constraint does impact the `set_max_skew` constraint.

Note: Exclusive clock groups (set with `set_clock_groups -exclusive`) override `set_max_skew` constraints.

The Timing Analyzer does not compare two paths for skew if their clocks are exclusive to each other. However, the Timing Analyzer does analyze for skew paths whose clocks are asynchronous.

Table 20. set_max_skew Options

Arguments	Description
`-h | -help`	Short help.
`-long_help`	Long help with examples and possible return values.
`-fall_from_clock <names>`	Valid source clocks (Tcl matches string patterns). Analysis only considers paths from falling clock edges.
`-fall_to_clock <names>`	Valid destination clocks (Tcl matches string patterns). Analysis only considers paths from falling clock edges.
`-from <names>`(2)	Valid sources (Tcl matches string patterns).

continued...

Arguments	Description
`-from_clock <names>`	Valid source clocks (Tcl matches string patterns).
`-get_skew_value_from_clock_period <src_clock_period|dst_clock_period|min_clock_period>`	Option to interpret skew constraint as a multiple of the clock period.
`-rise_from_clock <names>`	Valid source clocks (Tcl matches string patterns). Analysis only considers paths from rising clock edges.
`-rise_to_clock <names>`	Valid destination clocks (Tcl matches string patterns). Analysis only considers paths to rising clock edges.
`-skew_value_multiplier <multiplier>`	Value by which the clock period multiplies to compute skew requirement.
`-to <names>`[2]	Valid destinations (Tcl matches string patterns)
`-to_clock <names>`	Valid destination clocks (Tcl matches string patterns).
<skew>	The value of the skew you require.

Applying maximum skew constraints between clocks applies the constraint from all register or ports driven by the clock you specify (with the `-from` option) to all registers or ports driven by the clock you specify (with the `-to` option).

Maximum skew analysis can include data arrival times, clock arrival times, register micro parameters, clock uncertainty, on-die variation, and clock pessimism removal. Among these, the Fitter only disables clock pessimism removal by default.

Use `-get_skew_value_from_clock_period` to set the skew as a multiple of the launching or latching clock period, or whichever of the two has a smaller period. If you use this option, set `-skew_value_multiplier`, and you may not set the positional skew option. If more than one clock clocks the set of skew paths, Timing Analyzer uses the clock with smallest period to compute the skew constraint.

Click **Report Max Skew...** (`report_max_skew`) to view the max skew analysis. Since skew occurs between two or more paths, no results display if the `-from`/`-from_clock` and `-to`/`-to_clock` filters satisfy less than two paths.

Related Information

- report_max_skew Command, Quartus Prime Help

2.4.3.3. Net Delay (set_net_delay)

Use the `set_net_delay` command to set the net delays and perform minimum or maximum timing analysis across nets. A net delay constraint is invalid if there is a combinational cell between the From and To nodes.

(2) Legal values for the -from and -to options are collections of clocks, registers, ports, pins, cells or partitions in a design.

The `-from` and `-to` options can be string patterns or pin, port, register, or net collections. When you use pin or net collection, include output pins or nets in the collection.

```
set_net_delay -from reg_a -to reg_c -max 20
```

Table 21. set_net_delay Options

Arguments	Description
`-h | -help`	Short help.
`-long_help`	Long help with examples and possible return values.
`-from <names>`(3)	Valid source pins, ports, registers or nets (Tcl matches string patterns).
`-get_value_from_clock_period <src_clock_period|dst_clock_period| min_clock_period|max_clock_period>`	Option to interpret net delay constraint as a multiple of the clock period.
`-max`	Specifies maximum delay.
`-min`	Specifies minimum delay.
`-to <names>`(4)	Valid destination pins, ports, registers or nets (Tcl matches string patterns).
`-value_multiplier <multiplier>`	Value by which the clock period multiplies to compute net delay requirement.
`<delay>`	Delay value.

If you use the `-min` option, the Timing Analyzer calculates slack by determining the minimum delay on the edge. If you use `-max` option, the Timing Analyzer calculates slack by determining the maximum edge delay.

Use `-get_value_from_clock_period` to set the net delay requirement as a multiple of the launching or latching clock period, or whichever of the two has a smaller or larger period. If you use this option, you must not set the positional delay option. If more than one clock clocks the set of nets, the Timing Analyzer uses the net with the smallest period to compute the constraint for a `-max` constraint, and the largest period for a `-min` constraint. If no clocks are clocking the endpoints of the net (that is, if the endpoints of the nets are not registers or constraint ports), the Timing Analyzer ignores the net delay constraint.

Related Information

- Timing Exception Precedence on page 99
- report_net_delay Command, Quartus Prime Help

(3) If option is a wildcard ("*") character, all the output pins and registers on timing netlist become valid source points.

(4) If no option, or if option is a wildcard ("*") character, all the output pins and registers on timing netlist become valid destination points.

2.4.4. Timing Exception Constraints

Timing exception assignments allow you to modify (or provide exception to) the default timing analysis behavior to account for your specific design conditions.

You can specify the following timing constraints that modify the default timing analysis behavior:

- Set False Path
- Set Multicycle Path
- Set Minimum Delay
- Set Maximum Delay

Verify correct implementation of timing exception assignments by using the **Report Exceptions** (`report_exceptions`) command to report all exceptions to default timing analysis conditions.

Related Information

Report Exceptions on page 159

2.4.4.1. Timing Exception Precedence

If the same clock or node names occur in multiple timing exceptions, the Timing Analyzer observes the following order of timing exception precedence:

1. **Set False Path** (`set_false_path`) is the first priority. False paths and clock groups have identical priority, except when you use the `-latency_insensitive` or `-no_synchronizer` options with a false path exception. With either option, the false path has priority over a clock group.
2. **Set Clock Groups** (`set_clock_groups`) is the second priority.
3. **Set Minimum Delay** (`set_min_delay`) and **Set Maximum Delay** (`set_max_delay`) are the third priority.
4. **Set Multicycle Path** (`set_multicycle_path`) is the fourth priority.

The false path timing exception has the highest precedence. Within each category, assignments to individual nodes have precedence over assignments to clocks. For exceptions of the same type:

1. `-from <node>` is the first priority.
2. `-to <node>` is the second priority.
3. `-thru <node>` is the third priority.
4. `-from <clock>` is the fourth priority.
5. `-to <clock>` is the fifth priority.

An asterisk wildcard (*) for any of these options applies the same precedence as not specifying the option at all. For example, `-from a -to *` is treated identically to `-from a` with regards precedence.

Precedence example

1. `set_max_delay 1 -from x -to y`
2. `set_max_delay 2 -from x`
3. `set_max_delay 3 -to y`

The first exception has higher priority than either of the other two, since the first exception specifies a `-from` (while #3 does not) and specifies a `-to` (while #2 does not). In the absence of the first exception, the second exception has higher priority than the third, since the second exception specifies a `-from`, which the third does not. Finally, the remaining order of precedence for additional exceptions is order-dependent, such that the assignments most recently created overwrite, or partially overwrite, earlier assignments.

The `set_net_delay`, `set_max_skew`, and `set_data_delay` constraints analyze independently of minimum or maximum delays, or multicycle path constraints.

- The `set_net_delay` exception applies regardless of the existence of a `set_false_path` exception, or `set_clock_groups` exception, or other path-based constraint or exception. It is a net-based exception, and net-based and path-based exceptions are applied independently of each other.
- The `set_max_skew` exception applies on paths cut by an asynchronous clock group, and regardless of any `set_false_path` exception. Exclusive clock groups override max skew exceptions, because paths between exclusive clocks are entirely inactive and should not be analyzed for timing or skew requirements. This precedence allows you to define more targeted constraints on asynchronous CDC bus transfers.
- The `set_data_delay` exception specifies a maximum datapath delay exception for a given path. Exclusive clock groups override data delay exceptions, because paths between exclusive clocks are entirely inactive and should not be analyzed for timing or data delay requirements. Asynchronous clock groups do not override data delay exceptions. False path exceptions override data delay exceptions in the Quartus Prime Pro software version 21.2 and earlier. Beginning in version 21.3, false path exceptions do not override data delay exceptions. This change in precedence allows you to write more targeted constraints on asynchronous CDC bus transfers.

Verify correct implementation of timing exception assignments by using the **Report Exceptions** (`report_exceptions`) command to report all exceptions to default timing analysis conditions.

2.4.4.2. False Paths (set_false_path)

The **Set False Path** (`set_false_path`) constraint allows you to exclude a path from timing analysis, such as test logic or any other path not relevant to the circuit's operation. You can specify the source (`-from`), common through elements (`-thru`), and destination (`-to`) elements of that path.

The following SDC command makes false path exceptions from all registers starting with A, to all registers starting with B:

```
set_false_path -from [get_pins A*] -to [get_pins B*]
```

You can specify either a point-to-point or clock-to-clock path as a false path. A false path's `-from` and `-to` targets can be either nodes or clocks. However, the `-thru` targets can only be combinational nodes. For example, you can specify a false path for a static configuration register that writes once during power-up initialization, but does not change state again.

Although signals from static configuration registers often cross clock domains, you may not want to make false path exceptions to a clock-to-clock path, because some data may transfer across clock domains. However, you can selectively make false path exceptions from the static configuration register to all endpoints.

The Timing Analyzer assumes all clocks are related unless you specify otherwise. Use clock groups to more efficiently make false path exceptions between clocks, rather than writing multiple `set_false_path` exceptions between each clock transfer you want to eliminate.

Verify correct implementation of timing exception assignments by using the **Report Exceptions** (`report_exceptions`) command to report all exceptions to default timing analysis conditions.

2.4.4.3. Minimum and Maximum Delays

To specify an absolute minimum or maximum delay for a path, use the **Set Minimum Delay** (`set_min_delay`) or the **Set Maximum Delay** (`set_max_delay`) constraints, respectively. Specifying minimum and maximum delay directly overwrites existing setup and hold relationships with the minimum and maximum values.

Use the `set_max_delay` and `set_min_delay` constraints for asynchronous signals that do not have a specific clock relationship in your design, but require a minimum and maximum path delay. You can create minimum and maximum delay exceptions for port-to-port paths through the device without a register stage in the path. If you

use minimum and maximum delay exceptions to constrain the path delay, specify both the minimum and maximum delay of the path; do not constrain only the minimum or maximum value.

If the source or destination node is clocked, the Timing Analyzer takes into account the clock paths, allowing more or less delay on the data path. If the source or destination node has an input or output delay, the minimum or maximum delay check also includes that delay.

If you specify a minimum or maximum delay between timing nodes, the delay applies only to the path between the two nodes. If you specify a minimum or maximum delay for a clock, the delay applies to all paths where the clock clocks the source node or destination node.

You can create a minimum or maximum delay exception for an output port that does not have an output delay constraint. You cannot report timing for the paths that relate to the output port; however, the Timing Analyzer reports any slack for the path in the setup summary and hold summary reports. Because there is no clock that relates to the output port, the Timing Analyzer reports no clock for timing paths of the output port.

Note: To report timing with clock filters for output paths with minimum and maximum delay constraints, you can set the output delay for the output port with a value of zero. You can use an existing clock from the design or a virtual clock as the clock reference.

Verify correct implementation of timing exception assignments by using the **Report Exceptions** (`report_exceptions`) command to report all exceptions to default timing analysis conditions.

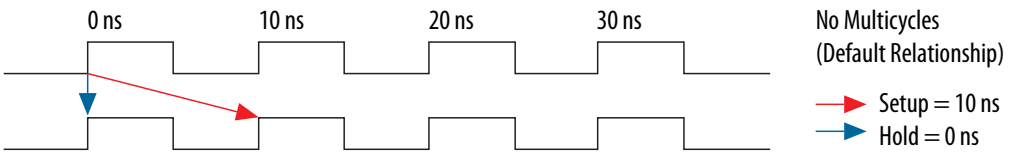
2.4.4.4. Multicycle Paths

By default, the Timing Analyzer performs a single-cycle analysis, which is the most restrictive type of analysis. When analyzing a path without a multicycle constraint, the Timing Analyzer determines the setup launch and latch edge times by identifying the closest two active edges in the respective waveforms.

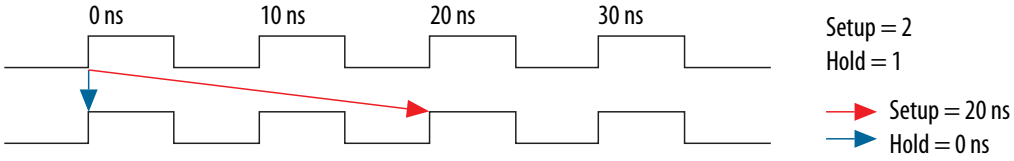
Figure 98. Default Setup and Hold Relationship (No Multicycle)



For hold time analysis, the timing analyzer analyzes the path for two timing conditions for every possible setup relationship, not just the worst-case setup relationship. Therefore, the hold launch and latch times can be unrelated to the setup launch and latch edges.

A multicycle constraint adjusts this default setup or hold relationship by the number of clock cycles you specify, based on the source (`-start`) or destination (`-end`) clock. A setup multicycle constraint of 2 extends the worst-case setup latch edge by one destination clock period. If you do not specify `-start` and `-end` values, the default constraint is `-end`.

Figure 99. Setup and Hold Relationship with Multicycle = 2



Hold multicycle constraints derive from the default hold position (the default value is 0). An end hold multicycle constraint of 1 effectively subtracts one destination clock period from the default hold latch edge.

When the objects are timing nodes, the multicycle constraint only applies to the path between the two nodes. When an object is a clock, the multicycle constraint applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock. When you adjust a setup relationship with a multicycle constraint, the default hold relationship adjusts automatically.

You can use timing constraints to modify either the launch or latch edge times that the Timing Analyzer uses to determine a setup relationship or hold relationship.

Table 22. Multicycle Constraints

Command	Modification
`set_multicycle_path -setup -end <value>`	Latch edge time of the setup relationship.
`set_multicycle_path -setup -start<value>`	Launch edge time of the setup relationship.
`set_multicycle_path -hold -end <value>`	Latch edge time of the hold relationship.
`set_multicycle_path -hold -start <value>`	Launch edge time of the hold relationship.

Verify correct implementation of timing exception assignments by using the **Report Exceptions** (`report_exceptions`) command to report all exceptions to default timing analysis conditions.

Related Information

Report Exceptions on page 159

2.4.4.4.1. Common Multicycle Applications

Multicycle exceptions adjust the timing requirements for a register-to-register path, allowing the Fitter to optimally place and route a design. Two common multicycle applications are relaxing setup to allow a slower data transfer rate, and altering the setup to account for a phase shift.

2.4.4.4.2. Relaxing Setup with Multicycle (set_multicyle_path)

You can use a multicycle exception when the data transfer rate is slower than the clock cycle. Relaxing the setup relationship increases the window when timing analysis accepts data as valid.

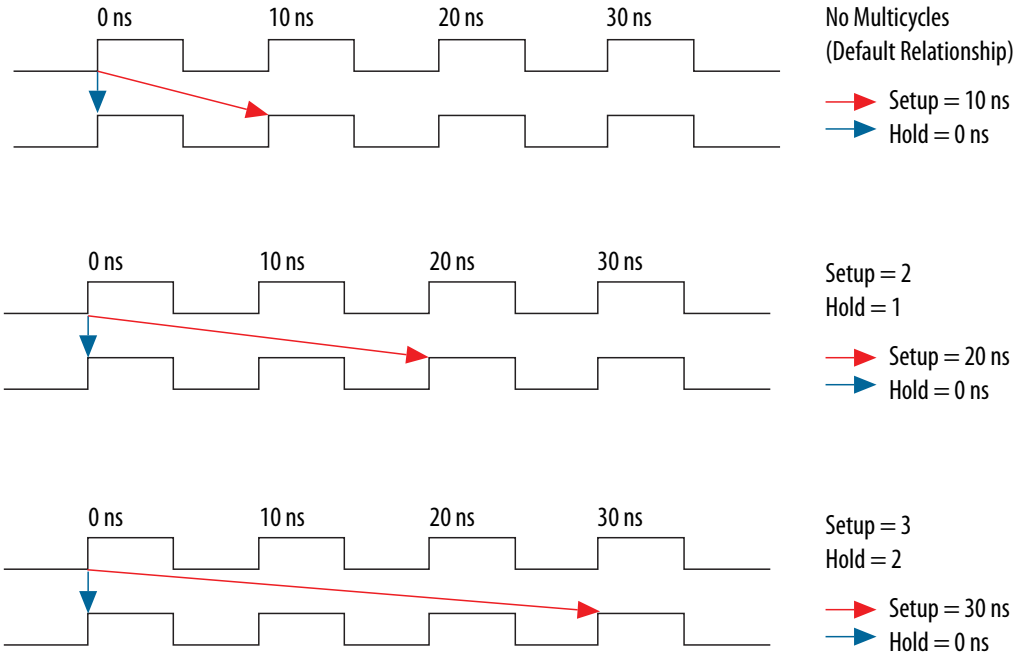
In the following example, the source clock has a period of 10 ns, but the clock enable signal controls a group of latching registers, so the registers only enable every other cycle. The 10 ns clock feeds registers , so the Timing Analyzer reports a setup of 10 ns and a hold of 0 ns. However, the data is transferring every other cycle, so the Timing Analyzer must analyze the relationships as if the clock is operating at 20 ns. The result is a setup of 20 ns, while the hold remains 0 ns, thus extending the window for data recognition.

The following pair of multicycle assignments relax the setup relationship by specifying the `-setup` value of N and the `-hold` value as N-1. You must specify the hold relationship with a `-hold` assignment to prevent a positive hold requirement.

Constraint to Relax Setup and Maintain Hold

```
set_multicycle_path -setup -from src_reg* -to dst_reg* 2
set_multicycle_path -hold -from src_reg* -to dst_reg* 1
```

Figure 100. Multicycle Setup Relationships



You can extend this pattern to create larger setup relationships to ease timing closure requirements. A common use for this exception is when writing to asynchronous RAM across an I/O interface. The delay between address, data, and a write enable may be several cycles. A multicycle exception to I/O ports allows extra time for the address and data to resolve before the enable occurs.

The following constraint relaxes the setup by three cycles:

Three Cycle I/O Interface Constraint

```
set_multicycle_path -setup -to [get_ports {SRAM_ADD[*] SRAM_DATA[*]} 3
set_multicycle_path -hold -to [get_ports {SRAM_ADD[*] SRAM_DATA[*]} 2
```

2.4.4.4.3. Accounting for a Phase Shift (-phase)

In the following example, the design contains a PLL that performs a phase-shift on a clock whose domain exchanges data with domains that do not experience the phase shift. This occurs when the destination clock phase-shifts forward, and the source clock does not shift. The default setup relationship becomes that phase-shift, thus shifting the window when data is valid.

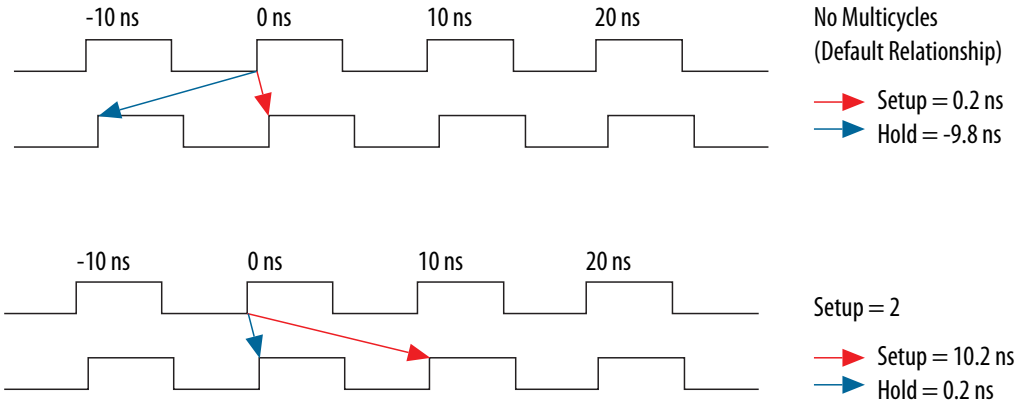
For example, the following code phase-shifts one output of a PLL forward by a small amount, in this case 0.2 ns.

Cross Domain Phase-Shift

```
create_generated_clock -source pll|inclk[0] -name pll|clk[0] pll|clk[0]
create_generated_clock -source pll|inclk[0] -name pll|clk[1] -phase 30 pll|clk[1]
```

The default setup relationship for this phase-shift is 0.2 ns, shown in Figure A, creating a scenario where the hold relationship is negative, which makes achieving timing closure nearly impossible.

Figure 101. Phase-Shifted Setup and Hold



The following constraint allows the data to transfer to the following edge:

```
set_multicycle_path -setup -from [get_clocks clk_a] -to [get_clocks clk_b] 2
```

The hold relationship derives from the setup relationship, making a multicycle hold constraint unnecessary.

2.4.4.5. Multicycle Exception Examples

The examples in this section illustrate how the multicycle exceptions affect the default setup and hold analysis in the Timing Analyzer. The multicycle exceptions apply to a simple register-to-register circuit. Both the source and destination clocks are set to 10 ns.

Verify correct implementation of timing exception assignments by using the **Report Exceptions** (`report_exceptions`) command to report all exceptions to default timing analysis conditions.

Related Information

Report Exceptions on page 159

2.4.4.5.1. Default Multicycle Analysis

By default, the Timing Analyzer performs a single-cycle analysis to determine the setup and hold checks. Also, by default, the Timing Analyzer sets the end multicycle setup assignment value to one and the end multicycle hold assignment value to zero.

The source and the destination timing waveform for the source register and destination register, respectively where HC1 and HC2 are hold checks 1 and 2 and SC is the setup check.

Figure 102. Default Timing Diagram

The timing waveforms show the source and destination registers of a data transfer. HC1 and HC2 are the hold checks that Timing Analyzer performs. SC is the setup check that Timing Analyzer performs.

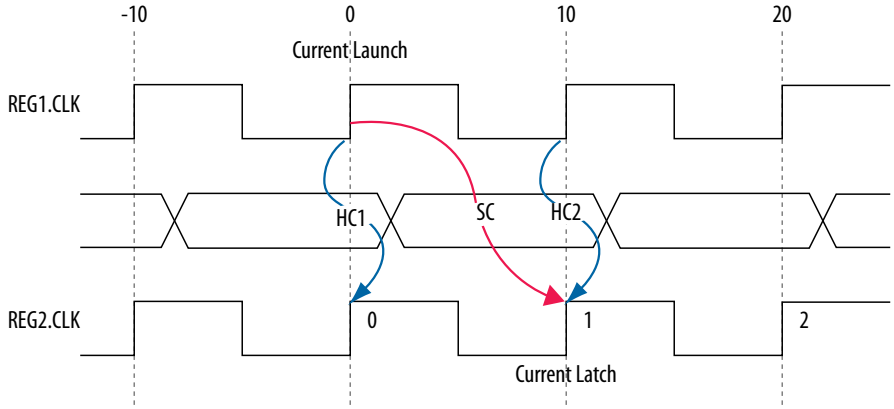

Figure 103. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 10\text{ ns} - 0\text{ ns} \\ &= 10\text{ ns} \end{aligned}$$

The most restrictive default single-cycle setup relationship, with an implied end multicycle setup assignment of one, is 10 ns.

Figure 104. Default Setup Report

2.4.4.5.2. End Multicycle Setup = 2 and End Multicycle Hold = 0

In this example, the end multicycle setup assignment value is two, and the end multicycle hold assignment value is zero.

Multicycle Constraint

```
set_multicycle_path -from [get_clocks clk_src] -to [get_clocks clk_dst] \
    -setup -end 2
```

Note: The Timing Analyzer does not require an end multicycle hold value because the default end multicycle hold value is zero.

In this example, the setup relationship relaxes by a full clock period by moving the latch edge to the next latch edge. The hold analysis is does not change from the default settings. The following shows the setup timing diagram for the analysis that the Timing Analyzer performs. The latch edge is a clock cycle later than in the default single-cycle analysis.

Figure 107. Setup Timing Diagram

The figure shows the setup timing diagram for the analysis that the Timing Analyzer performs. Without the multicycle constraint the latching edge is edge 1. However, with the multicycle constraint the latching edge is edge 2.

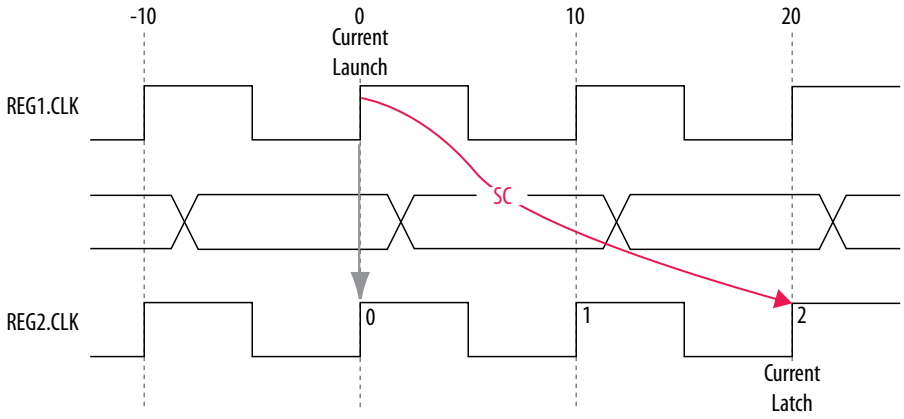

Figure 108. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 20\text{ ns} - 0\text{ ns} \\ &= 20\text{ ns} \end{aligned}$$

The most restrictive setup relationship with an end multicycle setup assignment of two is 20 ns. The following shows the setup report in the Timing Analyzer and highlights the launch and latch edges.

Figure 109. Setup Report with Setup Multicycle Exception

Path #1: Setup slack is 18.226

Path Summary | Statistics | Data Path | Waveform

Data Arrival Path

	Total	Incr	RF	Type	Element

4	21.953	-0.030			clock uncertainty
5	21.996	0.043		uTsu	dst

Because the multicycle hold latch and launch edges are the same as the results of hold analysis with the default settings, the multicycle hold analysis in this example is equivalent to the single-cycle hold analysis. The hold checks are relative to the setup check. Normally, the Timing Analyzer performs hold checks on every possible setup check, not only on the most restrictive setup check edges.

Figure 110. Hold Timing Diagram

The figure shows the hold latching edges are now at 10 and 20 ns, instead of 0 and 10 ns.

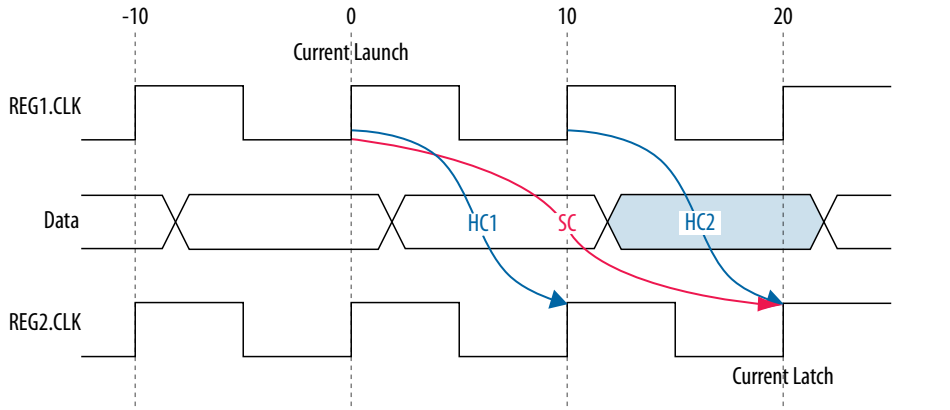

Figure 111. Hold Report with Setup Multicycle Exception

Figure 112. Hold Check Calculation

$$\begin{aligned} \text{hold check 1} &= \text{current launch edge} - \text{previous latch edge} \\ &= 0\ \text{ns} - 10\ \text{ns} \\ &= -10\ \text{ns} \end{aligned}$$

$$\begin{aligned} \text{hold check 2} &= \text{next launch edge} - \text{current latch edge} \\ &= 10\ \text{ns} - 20\ \text{ns} \\ &= -10\ \text{ns} \end{aligned}$$

2.4.4.5.3. End Multicycle Setup = 2 and End Multicycle Hold = 1

In this example, the end multicycle setup assignment value is two, and the end multicycle hold assignment value is one.

Multicycle Constraint

```
set_multicycle_path -from [get_clocks clk_src] -to [get_clocks clk_dst] \
    -setup -end 2
set_multicycle_path -from [get_clocks clk_src] -to
\[get_clocks clk_dst] -hold -end 1
```

In this example, the setup relationship relaxes by one clock period by moving the latching edge to the right of the default latching edge by 1 clock period. The hold relationship relaxes by one clock period by moving the latch edges to the left of the default latching edges by one.

The following shows the setup timing diagram for the analysis that the Timing Analyzer performs:

Figure 113. Setup Timing Diagram

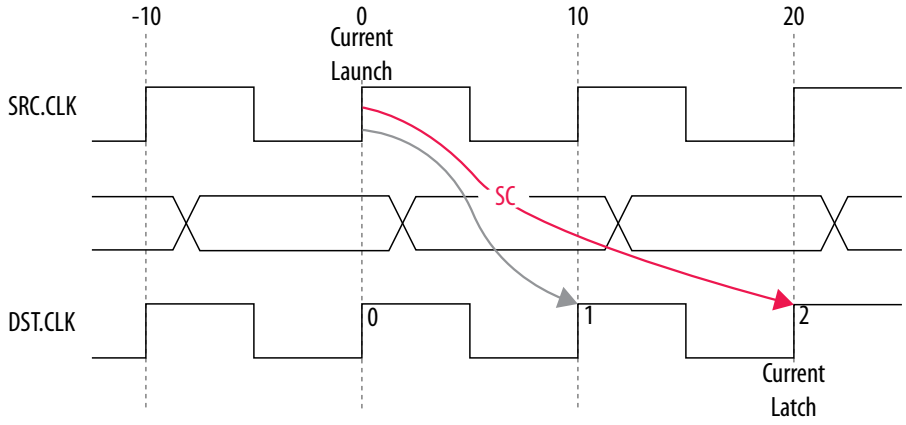

Figure 114. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 20\ \text{ns} - 0\ \text{ns} \\ &= 20\ \text{ns} \end{aligned}$$

The most restrictive hold relationship with an end multicycle setup assignment value of two is 20 ns.

The following shows the setup report for this example in the Timing Analyzer and highlights the launch and latch edges.

Figure 115. Setup Report with Setup and Hold Multicycle Exception

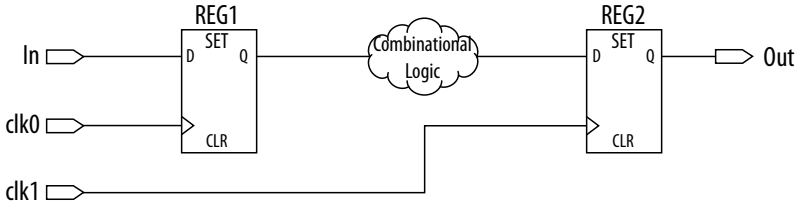
2.4.4.5.4. Same Frequency Clocks with Destination Clock Offset

In this example, the source and destination clocks have the same frequency, but the destination clock is offset with a positive phase shift. Both the source and destination clocks have a period of 10 ns. The destination clock has a positive phase shift of 2 ns with respect to the source clock.

The following example shows a design with the same frequency clocks and a destination clock offset.

Figure 119. Same Frequency Clocks with Destination Clock Offset Diagram



The following timing diagram shows the default setup check analysis that the Timing Analyzer performs.

Figure 120. Setup Timing Diagram

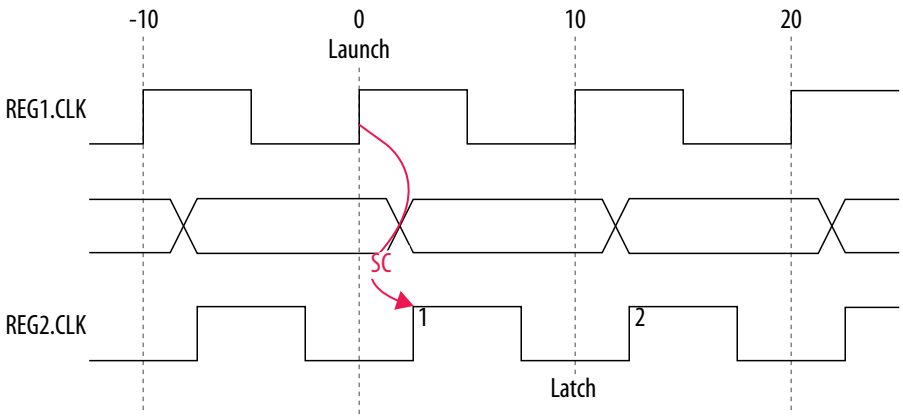


Figure 121. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 2\text{ ns} - 0\text{ ns} \\ &= 2\text{ ns} \end{aligned}$$

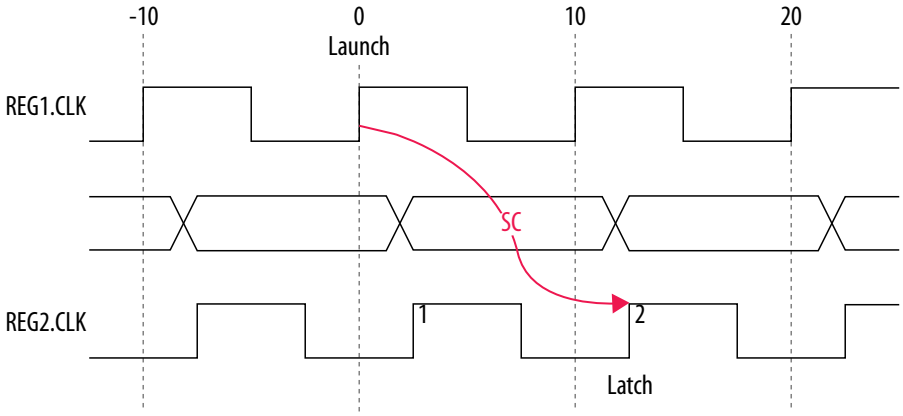
The setup relationship shown is too pessimistic and is not the setup relationship required for typical designs. To adjust the default analysis, you assign an end multicycle setup exception of two. The following shows a multicycle exception that adjusts the default analysis:

Multicycle Constraint

```
set_multicycle_path -from [get_clocks clk_src] -to [get_clocks clk_dst] \
     -setup -end 2
```

The following timing diagram shows the preferred setup relationship for this example:

Figure 122. Preferred Setup Relationship



The following timing diagram shows the default hold check analysis that the Timing Analyzer performs with an end multicycle setup value of two.

Figure 123. Default Hold Check

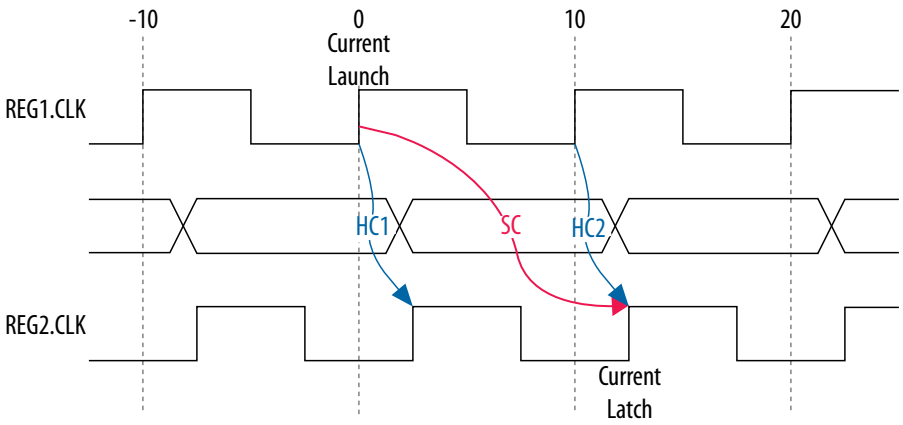


Figure 124. Hold Check Calculation

$$\begin{aligned} \text{hold check 1} &= \text{current launch edge} - \text{previous latch edge} \\ &= 0\ \text{ns} - 2\ \text{ns} \\ &= -2\ \text{ns} \end{aligned}$$

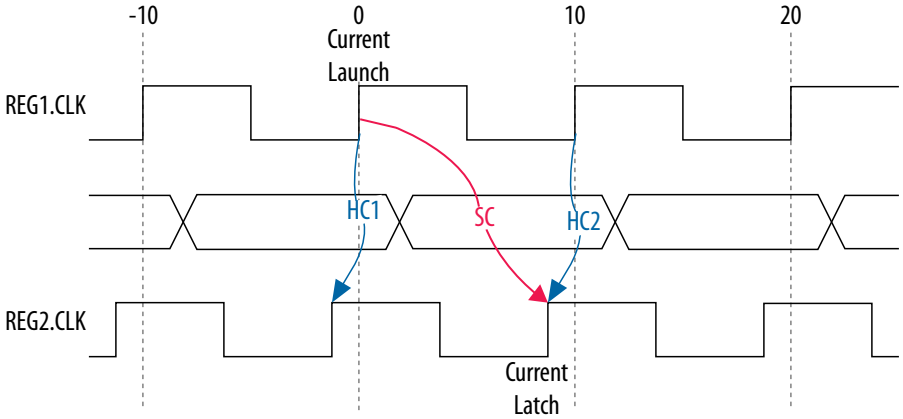
$$\begin{aligned} \text{hold check 2} &= \text{next launch edge} - \text{current latch edge} \\ &= 10\ \text{ns} - 12\ \text{ns} \\ &= -2\ \text{ns} \end{aligned}$$

In this example, the default hold analysis returns the preferred hold requirements and no multicycle hold exceptions are required.

The associated setup and hold analysis if the phase shift is –2 ns. In this example, the default hold analysis is correct for the negative phase shift of 2 ns, and no multicycle exceptions are required.

Figure 125. Negative Phase Shift

The figure shows an example of the setup and hold analysis for a negative phase shift of -2 ns. In this example, the default setup and hold analysis are correct, and no multicycle exceptions are required.

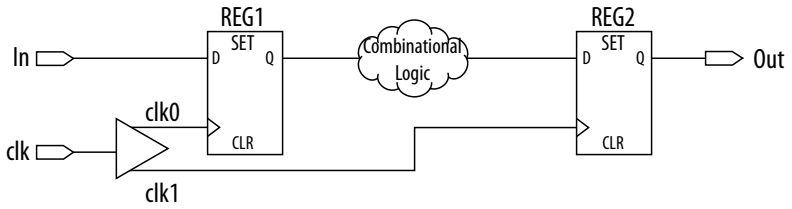


2.4.4.5.5. Destination Clock Frequency is a Multiple of the Source Clock Frequency

In this example, the destination clock frequency value of 5 ns is an integer multiple of the source clock frequency of 10 ns. The destination clock frequency can be an integer multiple of the source clock frequency when a PLL generates both clocks with a phase shift on the destination clock.

The following example shows a design in which the destination clock frequency is a multiple of the source clock frequency.

Figure 126. Destination Clock is Multiple of Source Clock



The following timing diagram shows the default setup check analysis that the Timing Analyzer performs:

Figure 127. Setup Timing Diagram

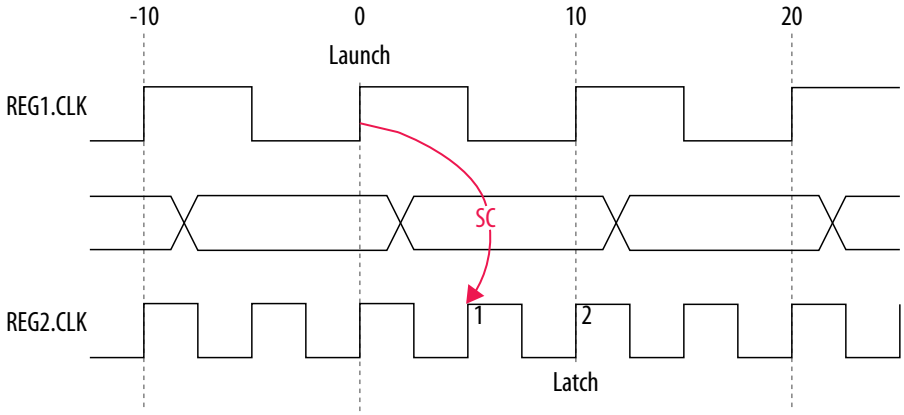


Figure 128. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 5\text{ ns} - 0\text{ ns} \\ &= 5\text{ ns} \end{aligned}$$

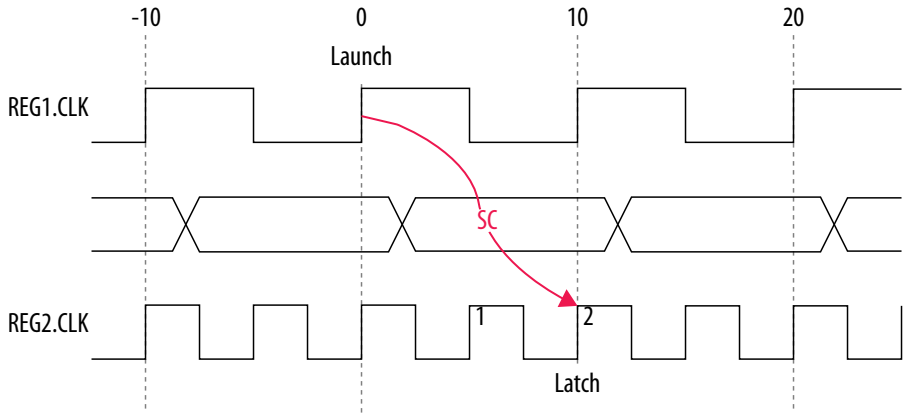
The setup relationship demonstrates that the data requires capture at edge two; therefore, you can relax the setup requirement. To correct the default analysis, you shift the latch edge by one clock period with an end multicycle setup exception of two. The following multicycle exception assignment adjusts the default analysis in this example:

Multicycle Constraint

```
set_multicycle_path -from [get_clocks clk_src] -to [get_clocks clk_dst] \
     -setup -end 2
```

The following timing diagram shows the preferred setup relationship for this example:

Figure 129. Preferred Setup Analysis



The following timing diagram shows the default hold check analysis the Timing Analyzer performs with an end multicycle setup value of two.

Figure 130. Default Hold Check

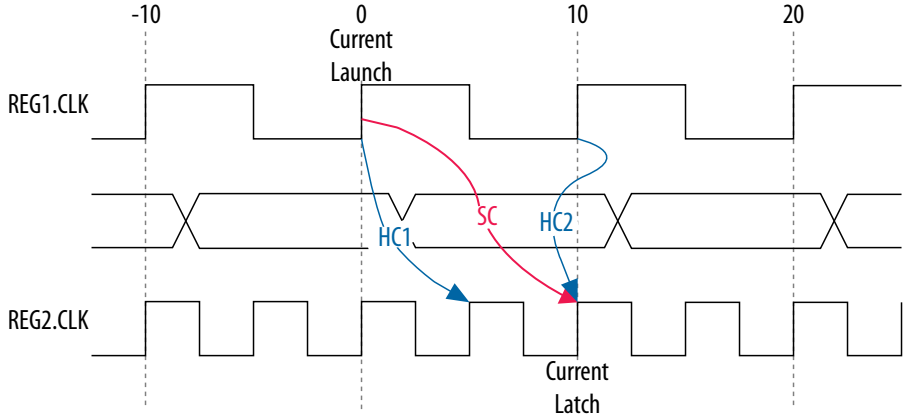


Figure 131. Hold Check Calculation

$$\begin{aligned} \text{hold check 1} &= \text{current launch edge} - \text{previous latch edge} \\ &= 0\ \text{ns} - 5\ \text{ns} \\ &= -5\ \text{ns} \end{aligned}$$

$$\begin{aligned} \text{hold check 2} &= \text{next launch edge} - \text{current latch edge} \\ &= 10\ \text{ns} - 10\ \text{ns} \\ &= 0\ \text{ns} \end{aligned}$$

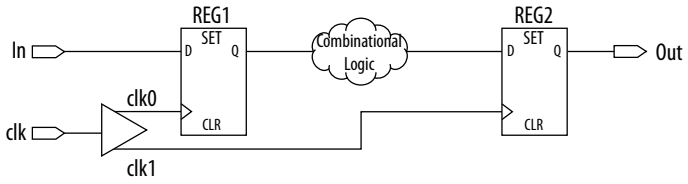
In this example, hold check one is too restrictive. The data is launched by the edge at 0 ns and must check against the data captured by the previous latch edge at 0 ns, which does not occur in hold check one. To correct the default analysis, you must use an end multicycle hold exception of one.

2.4.4.5.6. Destination Clock Frequency is a Multiple of the Source Clock Frequency with an Offset

This example is a combination of the previous two examples. The destination clock frequency is an integer multiple of the source clock frequency, and the destination clock has a positive phase shift. The destination clock frequency is 5 ns, and the source clock frequency is 10 ns. The destination clock also has a positive offset of 2 ns with respect to the source clock. The destination clock frequency can be an integer multiple of the source clock frequency. The destination clock frequency can be with an offset when a PLL generates both clocks with a phase shift on the destination clock.

The following example shows a design in which the destination clock frequency is a multiple of the source clock frequency with an offset.

Figure 132. Destination Clock is Multiple of Source Clock with Offset



The timing diagram for the default setup check analysis the Timing Analyzer performs.

Figure 133. Setup Timing Diagram

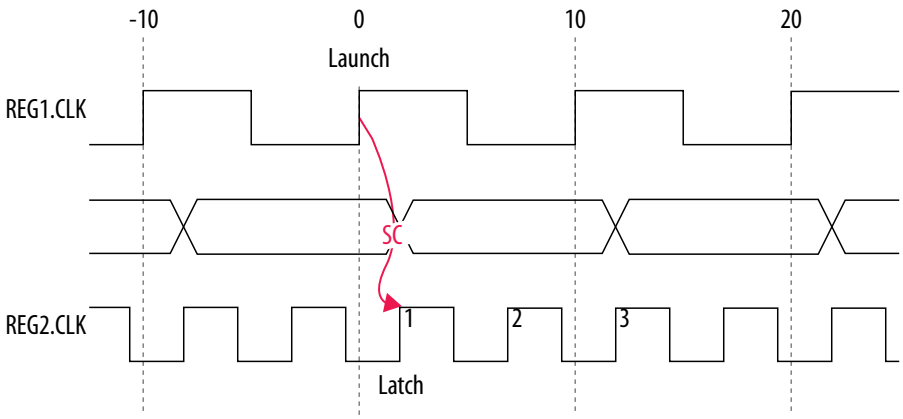


Figure 134. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 2\text{ ns} - 0\text{ ns} \\ &= 2\text{ ns} \end{aligned}$$

The setup relationship in this example demonstrates that the data does not require capture at edge one, but rather requires capture at edge three; therefore, you can relax the setup requirement. To adjust the default analysis, you shift the latch edge by two clock periods, and specify an end multicycle setup exception of three.

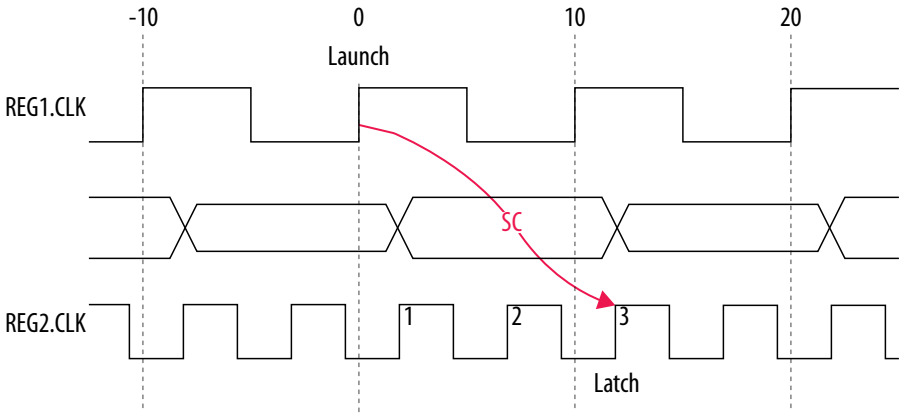
The multicycle exception adjusts the default analysis in this example:

Multicycle Constraint

```
set_multicycle_path -from [get_clocks clk_src] -to [get_clocks clk_dst] \
     -setup -end 3
```

The timing diagram for the preferred setup relationship for this example.

Figure 135. Preferred Setup Analysis



The following timing diagram shows the default hold check analysis that the Timing Analyzer performs with an end multicycle setup value of three:

Figure 136. Default Hold Check

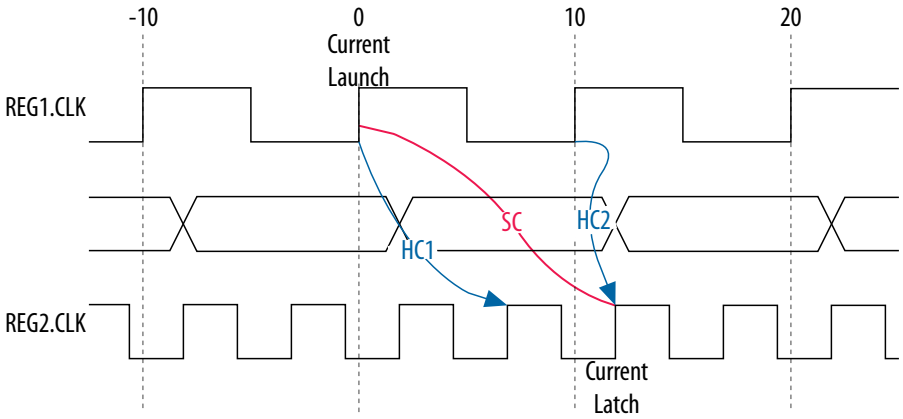


Figure 137. Hold Check Calculation

$$\begin{aligned} \text{hold check 1} &= \text{current launch edge} - \text{previous latch edge} \\ &= 0\text{ ns} - 7\text{ ns} \\ &= -7\text{ ns} \end{aligned}$$

$$\begin{aligned} \text{hold check 2} &= \text{next launch edge} - \text{current latch edge} \\ &= 10\text{ ns} - 12\text{ ns} \\ &= -2\text{ ns} \end{aligned}$$

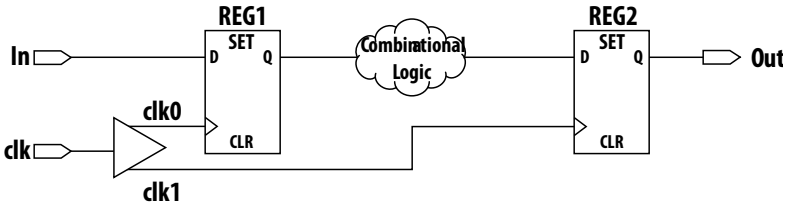
In this example, the hold check one is too restrictive. The data is launched by the edge at 0 ns, and must check against the data that the previous latch edge at 2ns captures. You can use the multicycle hold assignment of 1 to correct this.

2.4.4.5.7. Source Clock Frequency is a Multiple of the Destination Clock Frequency

In this example, the source clock frequency value of 5 ns is an integer multiple of the destination clock frequency of 10 ns. The source clock frequency can be an integer multiple of the destination clock frequency when a PLL generates both clocks and use different multiplication and division factors.

In the following example the source clock frequency is a multiple of the destination clock frequency:

Figure 138. Source Clock Frequency is Multiple of Destination Clock Frequency:



The following timing diagram shows the default setup check analysis the Timing Analyzer performs:

Figure 139. Default Setup Check Analysis

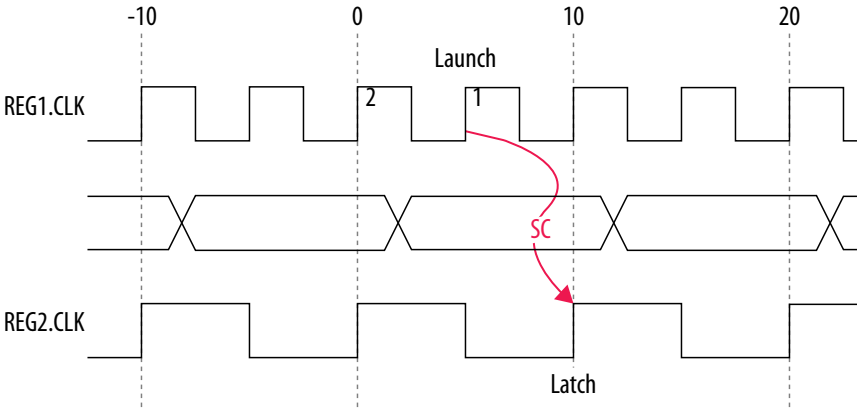


Figure 140. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 10\ \text{ns} - 5\ \text{ns} \\ &= 5\ \text{ns} \end{aligned}$$

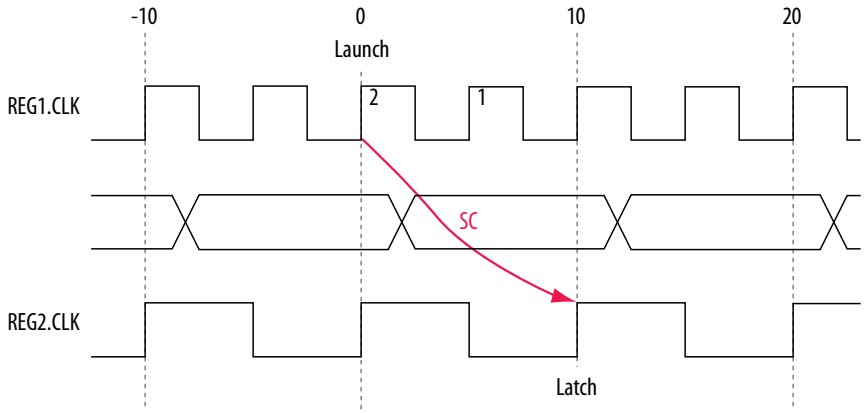
The setup relationship demonstrates that the data launched at edge one does not require capture, and the data launched at edge two requires capture; therefore, you can relax the setup requirement. To correct the default analysis, you shift the launch edge by one clock period with a start multicycle setup exception of two. The following multicycle exception adjusts the default analysis in this example:

Multicycle Constraint

```
set_multicycle_path -from [get_clocks clk_src] -to [get_clocks clk_dst] \
     -setup -start 2
```

The following timing diagram shows the preferred setup relationship for this example:

Figure 141. Preferred Setup Check Analysis



The following timing diagram shows the default hold check analysis the Timing Analyzer performs for a start multicycle setup value of two:

Figure 142. Default Hold Check

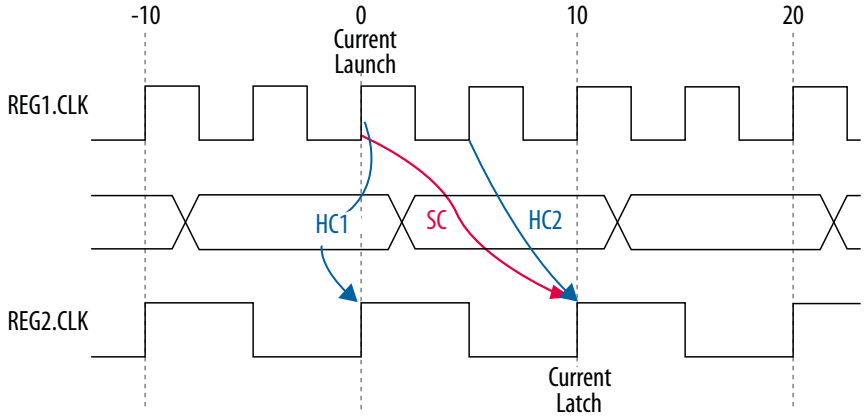


Figure 143. Hold Check Calculation

$$\begin{aligned} \text{hold check 1} &= \text{current launch edge} - \text{previous latch edge} \\ &= 0\text{ ns} - 0\text{ ns} \\ &= 0\text{ ns} \end{aligned}$$

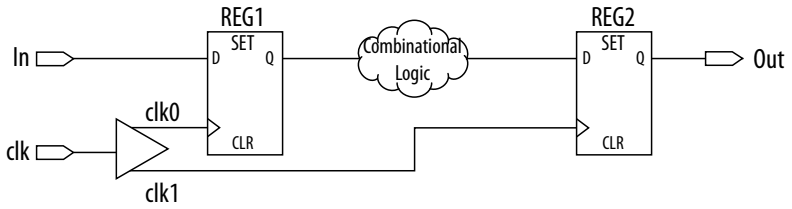
$$\begin{aligned} \text{hold check 2} &= \text{next launch edge} - \text{current latch edge} \\ &= 5\text{ ns} - 10\text{ ns} \\ &= -5\text{ ns} \end{aligned}$$

In this example, the hold check two is too restrictive. The data is launched next by the edge at 10 ns and must check against the data captured by the current latch edge at 10 ns, which does not occur in hold check two. To correct the default analysis, you use a start multicycle hold exception of one.

2.4.4.5.8. Source Clock Frequency is a Multiple of the Destination Clock Frequency with an Offset

In this example, the source clock frequency is an integer multiple of the destination clock frequency and the destination clock has a positive phase offset. The source clock frequency is 5 ns and destination clock frequency is 10 ns. The destination clock also has a positive offset of 2 ns with respect to the source clock. The source clock frequency can be an integer multiple of the destination clock frequency with an offset when a PLL generates both clocks with different multiplication.

Figure 144. Source Clock Frequency is Multiple of Destination Clock Frequency with Offset



The following timing diagram shows the default setup check analysis the Timing Analyzer performs:

Figure 145. Setup Timing Diagram

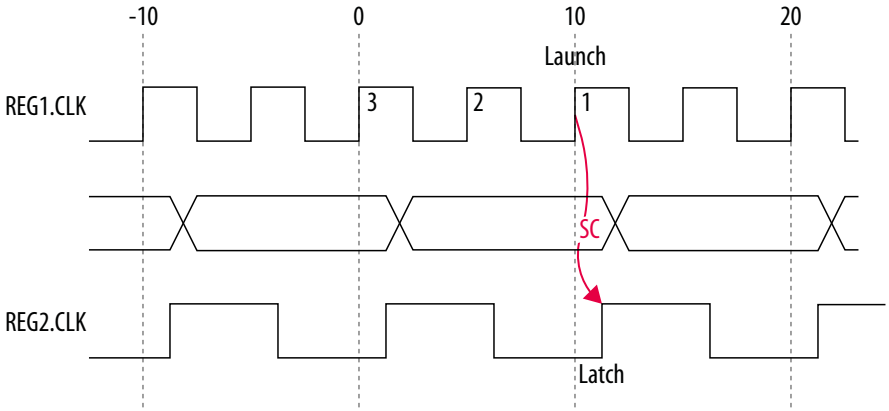


Figure 146. Setup Check Calculation

$$\begin{aligned} \text{setup check} &= \text{current latch edge} - \text{closest previous launch edge} \\ &= 12\text{ ns} - 10\text{ ns} \\ &= 2\text{ ns} \end{aligned}$$

The setup relationship in this example demonstrates that the data is not launched at edge one, and the data that is launched at edge three must be captured; therefore, you can relax the setup requirement. To correct the default analysis, you shift the launch edge by two clock periods with a start multicycle setup exception of three.

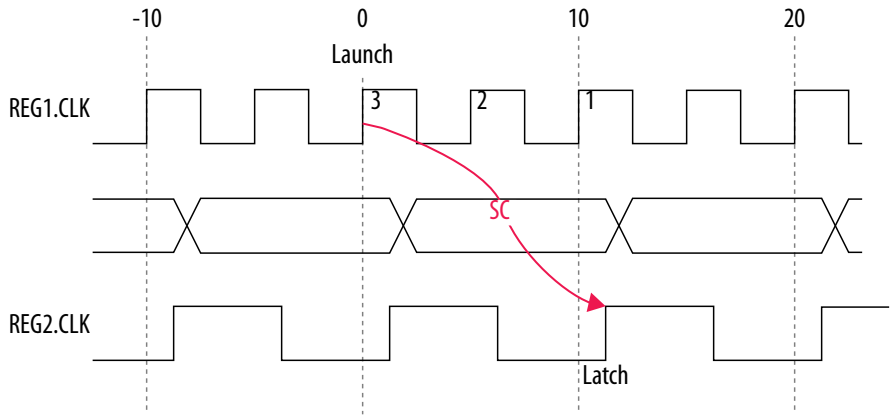
The following multicycle exception adjusts the default analysis in this example:

Multicycle Constraint

```
set_multicycle_path -from [get_clocks clk_src] -to [get_clocks clk_dst] \
     -setup -start 3
```

The following timing diagram shows the preferred setup relationship for this example:

Figure 147. Preferred Setup Check Analysis



The Timing Analyzer performs the following calculation to determine the hold check:

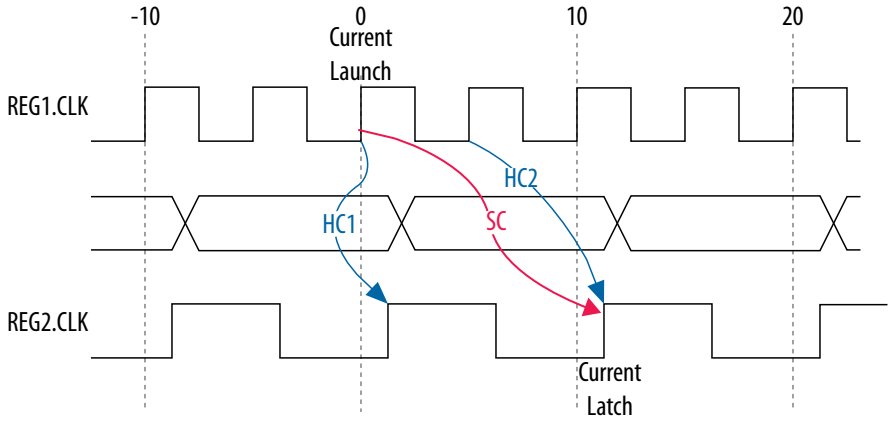
Figure 148. Hold Check Calculation

$$\begin{aligned} \text{hold check 1} &= \text{current launch edge} - \text{previous latch edge} \\ &= 0\text{ ns} - 2\text{ ns} \\ &= -2\text{ ns} \end{aligned}$$

$$\begin{aligned} \text{hold check 2} &= \text{next launch edge} - \text{current latch edge} \\ &= 5\text{ ns} - 12\text{ ns} \\ &= -7\text{ ns} \end{aligned}$$

The following timing diagram shows the default hold check analysis the Timing Analyzer performs for a start multicycle setup value of three:

Figure 149. Default Hold Check Analysis



In this example, the hold check two is too restrictive. The data is launched next by the edge at 10 ns and must check against the data captured by the current latch edge at 12 ns, which does not occur in hold check two. To correct the default analysis, you must specify a multicycle hold exception of one.

2.4.5. Delay Annotation

To modify the default delay values used during timing analysis, use the `set_annotated_delay` and `set_timing_derate` commands. You must update the timing netlist to apply these commands.

To specify different operating conditions in a single `.sdc` file, rather than having multiple `.sdc` files that specify different operating conditions, use the `set_annotated_delay -operating_conditions` command.

Related Information

- set_annotated_delay Command, Quartus Prime Help

2.5. Timing Report Descriptions

The Timing Analyzer generates only a subset of all available reports by default, including the Setup Summary and Timing Analyzer Summary reports. However, you can generate dozens of other detailed reports in the Timing Analyzer GUI, or with command-line commands to help pin-point timing issues. You can customize the display of information in the reports.

You can automatically generate reports that are useful to you, to display after opening a project in the stand-alone Timing Analyzer GUI, as The quartus_staw executable describes.

The following section describes a partial list of all the timing analysis reports that you can generate:

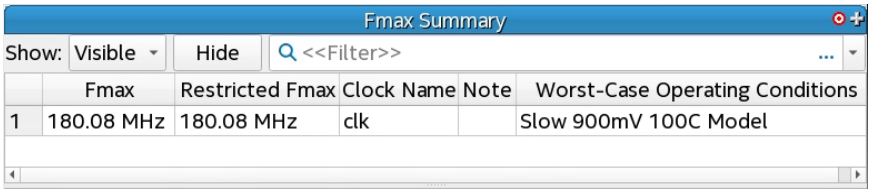
Related Information

Step 4: Analyze Timing Reports on page 40

2.5.1. Report Fmax Summary

The Timing Analyzer **Reports ➤ Datasheet ➤ Report Fmax Summary** command generates a report panel showing the potential maximum frequency for every clock in your design. The **Fmax** column reports the fastest frequency that your clock can run, and still pass `report_timing -setup -intra_clock` with a slack of `0`. The equivalent console command is `report_clock_fmax_summary`.

Figure 150. Fmax Summary Report



Note: The related `get_clock_fmax_info` command returns a Tcl list, which is useful for scripting and parsing. Refer to *get_clock_fmax_info (::quartus::sta)* in *Quartus Prime Pro Edition User Guide Scripting*.

Timing analysis only computes f_{MAX} for paths where the source and destination registers or ports are driven by the same clock. Timing analysis ignore paths of different clocks, including generated clocks. For paths between a clock and its inversion, the Timing Analyzer computes f_{MAX} as if the rising and falling edges of the clock scale along with f_{MAX}, such that duty cycle (by percentage) is maintained.

However, the **Fmax** report does not indicate whether your design meets timing for recovery, removal, nor setup or hold without the `intra_clock` option. For these reasons, always make sure to view the Setup, Hold, Recovery, Removal, and Min Pulse Width slack summaries to determine whether your design meets timing.

The **Restricted Fmax** column reports the lesser of the following values:

- The fastest frequency that your clock can run, and still pass `report_timing -hold -intra_clock` with a slack of `0` or `report_min_pulse_width` with a slack of `0`.
- The **Fmax** column value.(5)

Restricted Fmax considers hold timing in addition to setup timing, as well as minimum pulse and minimum period restrictions. Similar to unrestricted f_{MAX}, the analysis computes the restricted f_{MAX} as if the rising and falling edges of the clock scale along with f_{MAX}, such that the duty cycle (in terms of a percentage) is maintained.

The **Restricted Fmax** may display text indicating any of the following limiting factors:

- Limit due to hold check
- Limit due to minimum pulse width restriction
- Limit due to high minimum pulse width restriction
- Limit due to low minimum pulse width restriction

(5) The **Restricted Fmax** column never reports a value higher than the **Fmax** column.

Typically, hold checks do not limit the maximum frequency (f_{MAX}) because the checks are for same-edge relationships, and therefore independent of clock frequency. For example, when launch equals zero and latch equals zero. However, with an inverted clock transfer, or a multicycle transfer, the hold relationship is not a same-edge transfer and changes with the clock frequency.

Refer to the timing reports, such as those that you can generate using `report_timing`, or using minimum pulse width reports via the `report_min_pulse_width` command for details of specific paths, registers, or ports.

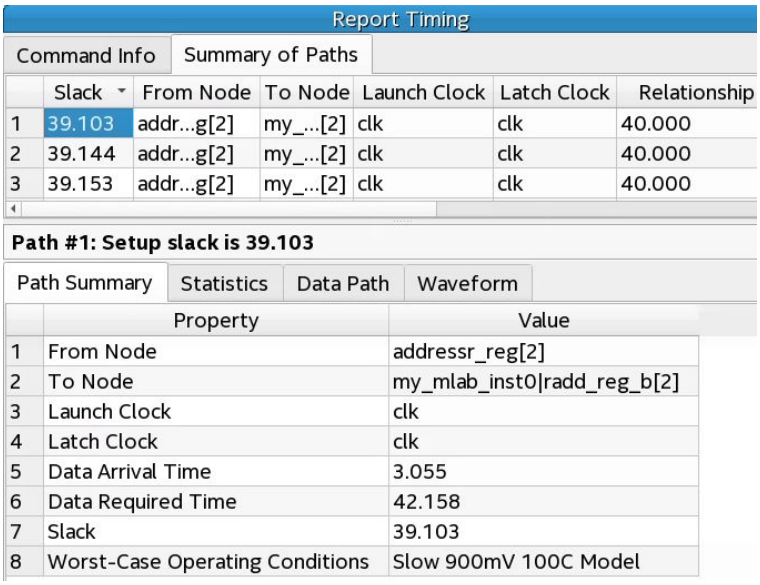
Quartus Prime Pro Edition User Guide: Scripting

2.5.2. Report Timing

The Timing Analyzer's **Reports ➤ Timing Slack ➤ Report Timing...** command allows you to specify settings to report the timing of any path or clock domain in the design. The equivalent scripting command is `report_timing`.

Figure 151. Report Timing Report



You can specify diverse options to customize the reporting. You can specify the **Clocks** and **Targets** that the report displays, the **Analysis Type** to run, whether to display **Extra Info** in the report, and the **Output** options for the report. For example, you can increase the number of paths to report, add a **Target** filter, and add a **From Clock**.

Figure 152. Report Timing Dialog Box (Top Section)

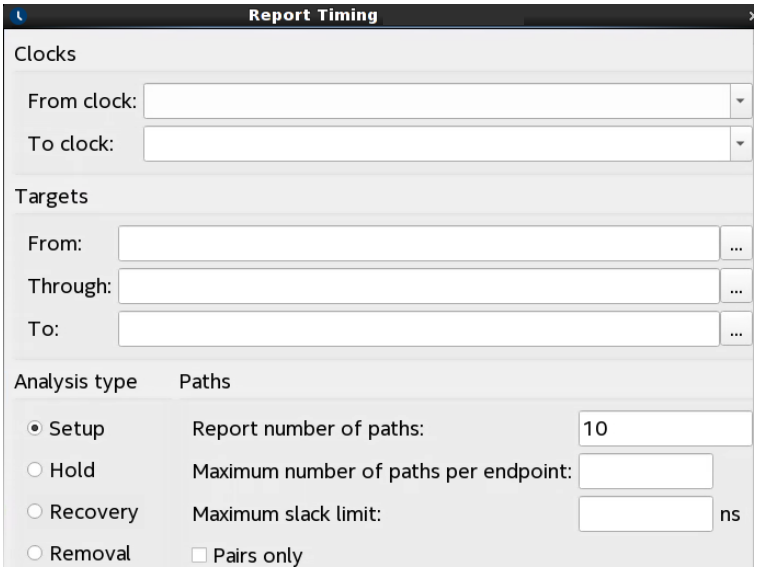


Figure 153. Report Timing Dialog Box (Bottom Section)

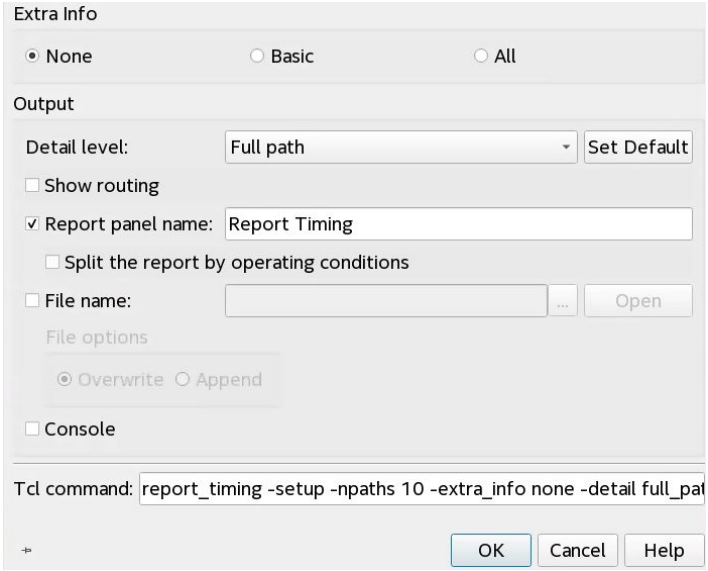

Table 23. Report Timing Settings

Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Targets	Specifies the target node for **From Clock** and **To Clock** to report paths with only those endpoints. Specify an I/O or register name or I/O port for this option. The field also supports wildcard characters. For example, to report only paths within a specific hierarchy: `report_timing -from *|egress:egress_inst|* \` `-to *|egress:egress_inst|* -(other options)`

continued...

Option	Description
	When the **From**, **To**, or **Through** boxes are empty, the Timing Analyzer assumes all possible targets in the device. The **Through** option limits the report to paths that pass through combinatorial logic, or a particular pin on a cell.
Analysis type	The **Analysis type** options are **Setup**, **Hold**, **Recovery**, or **Removal**. The Timing Analyzer reports the results for the type of analysis you select.
Paths	Specifies the number of paths to display by endpoint and slack level. The default value for **Report number of paths** is 10, otherwise, the report can be very long. Enable **Pairs only** to list only one path for each pair of source and destination. Limit further with **Maximum number of paths per endpoints**. You can also filter paths by entering a value in the **Maximum slack limit** field.
Extra Info	Provides additional data that is relevant for diagnosing timing failure root cause, such as setup slack breakdown, and unexpected routing detours caused by congestion and hold time fix-up. Specify whether to include **None**, **Basic**, or **All** extra information in the report. The **Extra Info** tab data can help you identify potential, unnecessary routing detours, as well as placement or circuit issues that restrict the path f_{MAX} performance. Refer to Setup Slack Breakdown On the Extra Info Tab on page 131. • **All**—report includes **Extra Info** tab that reports extra information for source timing endpoints that pass through the unregistered output of a RAM or DSP block, or for destination timing endpoints that pass through the unregistered input of a DSP block. The **Data Path** tab includes Estimated Delay Added for Hold and Route Stage Congestion Impact data. • **Basic**—report includes the **Extra Info** tab but no extra information on the **Data Path** tab. • **None**—report includes no **Extra Info** tab or other extra information on the **Data Path** tab.
Output	Specify the path types the analysis includes in output for **Detail level**: • **Summary**—level includes basic summary reports. Review the **Clock Skew** column in the **Summary** report. If the skew is less than +/-150ps, the clock tree is well balanced between source and destination. • **Path only**—displays all the detailed information, except the **Data Path** tab displays the clock tree as one line item. • **Path and Clock**—displays the same as **Path only** with respect to the clock. • **Full path**—when higher clock skew is present, enable the **Full path** option. This option breaks the clock tree into greater detail, showing every cell, including the input buffer, PLL, global buffer (called CLKCTRL_), and any logic. Review this data to determine the cause of clock skew in your design. Use the **Full path** option for I/O analysis because only the source clock or destination clock is inside the FPGA, and therefore the delay is a critical factor to meet timing.
Show routing	Shows routing data in the report.
Split the report by operating conditions	For the operating condition timing corners, subdivides the data by each operating condition.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

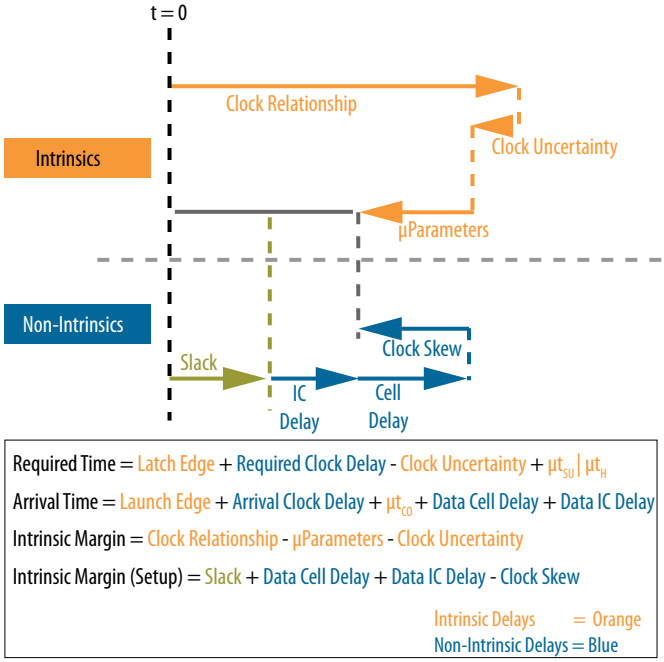
Setup Slack Breakdown On the Extra Info Tab

The **Extra Info** tab contains other timing metrics to help you diagnose timing closure issues, including **Setup Slack Breakdown** for the path.

The slack of a path specifies the margin by which the path meets its timing requirement. The setup slack breakdown is a numeric value that the Timing Analyzer calculates from the following timing requirements and path element delays:

Figure 155. Setup Slack Breakdown Calculations



A path can fail timing requirements for many varied reasons. For example, the clock relationship can be impossibly tight, or there can be excessive routing delays that alone cause failure for the timing path. Calculating the intrinsic margin of a timing path, and then comparing that margin to other delays of the path, can help identify the specific reasons why a path fails its timing requirement.

The **Extra Info** tab can help you identify potential significant or unexpected routing detours caused by congestion and hold time fix-up. The **Extra Info** tab can also report extra information for source timing endpoints that pass through the unregistered output of a RAM or DSP block, or for destination timing endpoints that pass through the unregistered input of a DSP block.

You can review the **Extra Info** data and **Locate Path** or **Locate Chip Area** in Chip Planner, Technology Map Viewer, or Resource Property Viewer to determine whether to make changes to improve placement and routing.

Some delay elements are more sensitive to a path's placement and routing than others. Intrinsic delays that are part of **Setup Slack Breakdown** are less sensitive to placement and routing, and are inherent in the RTL and timing requirements. Non-intrinsic delays are the other delays that are sensitive to placement and routing.

Table 24. Extra Info Tab Data

Extra Info Data	Description
Intrinsic Margin	Reports the intrinsic and non-intrinsic timing elements that comprise the timing path slack value. Intrinsic margin is a numeric value that the Timing Analyzer calculates from the timing requirements and path element delays. The Timing Analyzer also derives the slack of the path from the same requirements and delays, but with a different calculation. Intrinsic delays are less sensitive to placement and routing, and are inherent in the RTL and timing requirements. Non-intrinsic delays are the other delays that are sensitive to placement and routing.
From Node Info	Specifies the node Type, any Retiming Restriction, and any Power-Up "Don't Care" attributes for the From Node. Consider removing the retiming restriction to allow retiming and improve performance for timing closure.
To Node Info	Specifies the node Type, any Retiming Restriction, and any Power-Up "Don't Care" attributes for the To Node. Consider removing the retiming restriction to allow retiming and improve performance for timing closure.
Max Fanout	Reports the maximum fan-out of register and combinational nodes in the path.
Route Stage Congestion Impact	Reports whether routing has a **Low**, **Medium**, or **High** impact on congestion. A **Low** value suggests timing issues are not congestion related. A **High** value suggests competition for scarce routing resources plays a role in poor timing.
Estimated Delay Added for Hold	Reports the estimated amount of delay added on to the fastest delay route to satisfy hold. This value can help you determine whether delays are routing congestion or Hold related.
Sufficient Setup Margin for Hold	Reports whether the setup margin is suitable for the hold timing. **Yes**, indicates that the setup margin is sufficient. **No** indicates that the setup margin is insufficient for hold timing.
Source/Destination Bounding Box	Reports the lower-left and upper-right coordinates for the boundary box enclosing the source and destination registers. In an ideal case, the **Source/Destination Bounding Box**, **Cell Bounding Box**, and **Interconnect Bounding Box** values are roughly the same, and the relative areas are approximately 1.0. If the cell bounding box size grows relative to the **Source/Destination Bounding Box**, that can indicate a potential unnecessary routing detour on the path.
Source/Destination Area Covered	Reports the total area covered in terms of LABs.
Source/Destination Relative Area	Reports the area for the source and destination, relative to the **Source/Destination Bounding Box**. The value is always 1.0, which equals the same size.
Cell Bounding Box	Reports the lower-left and upper-right coordinates for the boundary box enclosing the source and destination registers, and any cells in the path.
Cell Area Covered	Reports the area for the cell, relative to the **Source/Destination Bounding Box**. A value of 1.0 equals the same size. A value greater than 1.0 can indicate a path has a cell outside of the space between the registers in the path.

The following describe the interpretation of timing conditions indicated by the **Setup Slack Breakdown**:

- **When the Setup Slack Breakdown is less than 0**—the path has such a tight timing relationship, a significant difference in microparameters, or such significant clock source uncertainty, that the path fails before the addition of any delay. Review the SDC constraints to verify that the timing relationship is correct. An incorrect relationship can exist between unrelated clocks that lack the proper timing cut. Ensure that parameterizable hard blocks (such as 20K RAM and DSP blocks) are fully registered. Investigate clock sources to verify that the clocks use global signals for routing.
- **When the clock skew exceeds the Setup Slack Breakdown**—address the clock transfer to meet timing on the path. You may need to create clock region assignments. You might also need to redesign cross-clock transfers to switch from synchronous to asynchronous implementation, such as with a FIFO or other handshake.

- **When the cell delay is greater than its intrinsic margin**—reduce the cell delay, as the path would fail timing even if the clocks are perfect and use no routing wires. Rewrite RTL to reduce the logic depth, restructure logic to allow the Compiler to use faster LUT inputs, or unblock retiming optimizations. The Compiler can automatically retime registers to reduce logic depth, but only in ways that maintain functionality and that the device architecture supports. To unblock the Hyper-Retimer, remove asynchronous resets and initial conditions.
- **When the interconnect delay is greater than its intrinsic margin**—the path would fail timing even if the clocks are perfect, and there is no logic. This occurs if registers are too far apart, or a timing path detours around a congested chip area. Review the fan-in and fan-out of registers that are far apart. Apply Logic Lock regions so the Fitter places the registers closer together. Use Logic Lock regions only after determining why placement is initially poor.

2.5.3. Report Timing By Source Files

The Timing Analyzer's **Reports ➤ Timing Slack ➤ Report Timing By Source Files** command allows you to specify settings to report the timing of any path or clock domain in the design, similar to Report Timing on page 128. However, **Report Timing By Source Files** groups the timing paths by the containing entity, and groups the entities by the source file that defines the entity.

This report allows you to attribute timing paths to exactly one instance in the design. The Path TNS column shows the sum of all negative slacks within a file or entity. The equivalent scripting command is `report_timing_by_source_files`.

From the report in the Timing Analyzer GUI, you can right-click on any source file to open it in a text editor to easily investigate timing paths within a particular source file.

2.5.4. Report Data Delay

You can run the Timing Analyzer's **Reports ➤ Other Slack Analyses ➤ Report Data Delay...** command to generate a custom report showing the worst-case slack for the datapath delay exception for a given path. The report shows only paths covered by data delay (`set_data_delay`) constraints, including paths whose non-datapath analysis is cut by a false path.

Note: Exclusive clock groups (set with `set_clock_groups -exclusive`) override `set_data_delays` constraints.

Related Information

Timing Exception Precedence on page 99

2.5.5. Report Net Delay

The Timing Analyzer's **Reports ➤ Other Slack Analyses ➤ Report Net Delay...** command to configure and display a customized report that details the results of net delay analysis, as defined by timing constraints and exceptions.

Each `set_net_delay` command is treated as a separate analysis and `report_net_delay` reports the results of all `set_net_delay` commands in a single report. The report contains each `set_net_delay` command with the worst case slack result followed by the results of each edge matching the criteria set by that `set_net_delay` command. These results are ordered based on the slack value.

2.5.6. Report Clocks and Clock Network

The Timing Analyzer's **Reports ➤ Clocks ➤ Report Clocks** command reports all clock signals in the design. The equivalent scripting command is `report_clocks`.

Report Clocks generates the Clock Summary report that lists details about all of the signals with clock setting constraints in the design.

Figure 156. Clock Summary Report Shows Properties of Clock Signals in Design

Clocks Summary

Show: Visible | Hide | <<Filter>>

	Clock Name	Type	Period	Frequency	Rise	Fall	Duty Cycle	Divide by	Multiply by	Phase	Offset
1	clk	Base	40.000	25.0 MHz	0.000	20.000					

Similarly, you can click the **Reports ➤ Clocks ➤ Report Clock Network...** command to generate a custom report that helps you identify and evaluate advanced clock structures, such as clock muxes, clock gates, and clock dividers.

Figure 157. Report Clock Network Dialog Box

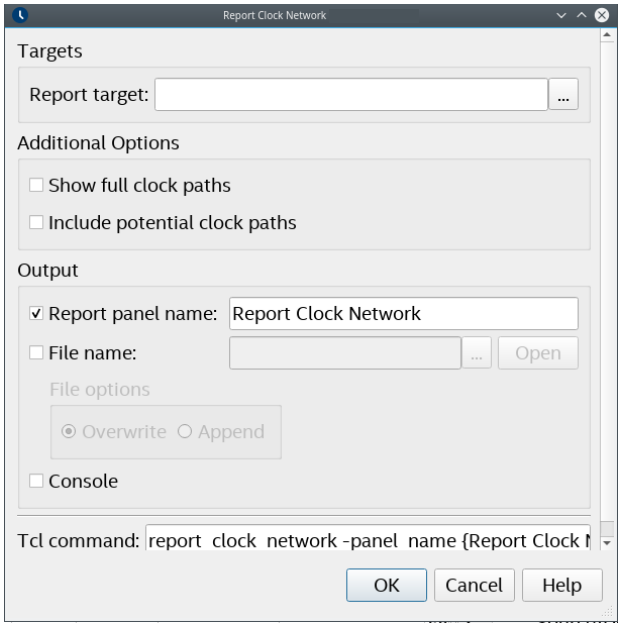

Table 25. Report Clock Network Dialog Box Settings

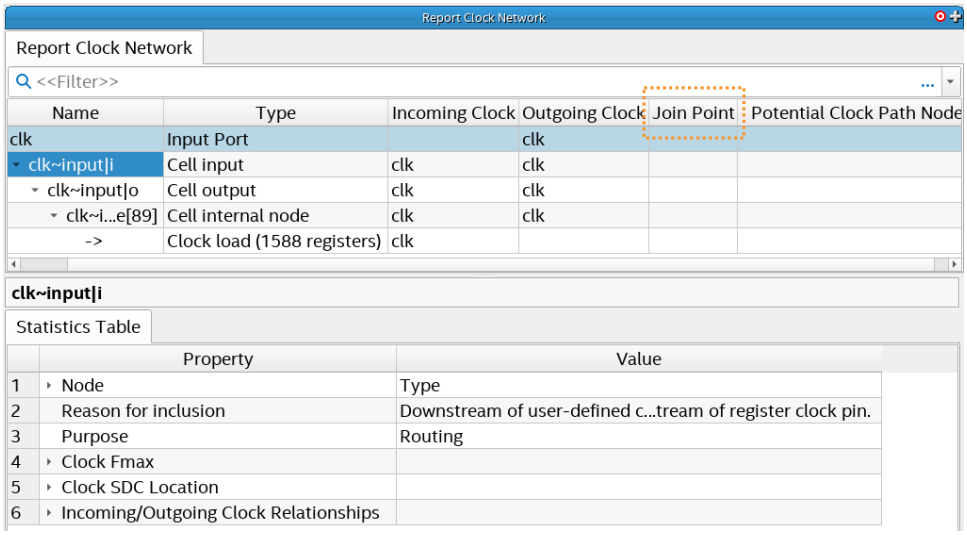
Option	Description
Report target	Specifies the collection of clocks and nodes that you want to analyze and report.
Expand clock path	Displays all subordinate nodes in expanded view. The default display collapses trivial nodes in the report.
Include potential clock paths	Includes nodes in the report that are not on a clock path, but are upstream of a register clock port.
Report panel name	Specifies the name that appears in the report panel title bar.
File name	Specifies the name of an optional output file to contain report data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

This report shows the nodes on the clock network hierarchically, starting from the input clock ports, followed by any other nodes that transform or route the clocks to the clock loads. The **Join Points** indicate whether the clock network has convergence, such as with clock muxes. The **Statistics Table** provides more details about the signals that you select in the report, such as the relationships between the incoming and outgoing clocks of this node.

Figure 158. Report Clock Network Report

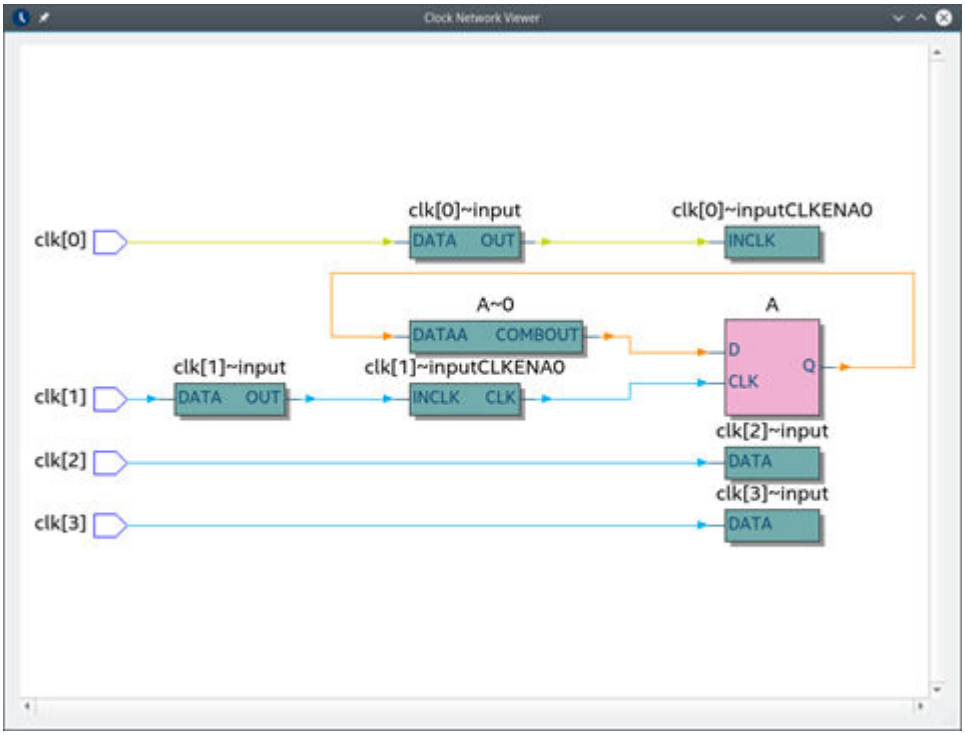


Right-click any of the nodes in the Clock Network report to click **Open Clock Network Viewer**. The Clock Network Viewer displays a graphical representation of the clock domains and constraints on the clock network to help you to see clock tree problems, such as signals entering and exiting globals. Use this graphical view to determine which clocks drive portions of the design. The Clock Network Viewer color codes the clock connection edge to indicate the clock types.

- Blue—the base clock
- Orange—a derived clock
- Green—a multicycle clock

The display shows a truncated signal name by default. Hover the mouse over the clock signals to display the full signal name. Right-click any signal to display the **Color Legend**. Click the **Zoom** controls to view more detail. You can export the schematic view as a PDF from the right-click menu.

Figure 159. Clock Network Viewer



You can also right-click and choose **Report Paths from Node**, **Report Paths Thru Node**, **Report Paths To Node**, or **Focus On Node** to rerun the report on the selected node.

2.5.7. Report Clock Transfers

The Timing Analyzer's **Reports ➤ Clock Domain Crossings ➤ Report Clock Transfers** command reports all clock-to-clock transfers in the design. The equivalent scripting command is `report_clock_transfers`.

Report Clock Transfers generates the Setup Transfers report and the Hold Transfers report that display data about the clock-to-clock transfers.

Figure 160. Setup Transfers Report Shows Clock-to-Clock Transfers

Setup Transfers

Show: Visible | Hide | <<Filter>>

	From Clock	To Clock	RR Paths	FR Paths	RF Paths	FF Paths	Clock Pair Classification	Worst-Case Slack	Worst-Case Operating Conditions
1	clock	clock	34	0	0	0	Intra-Clock (Timed Safe)	3.319	Slow vid2 100C Model

The Setup Transfers report and Hold Transfers report display all possible transfers, including rising clock edge to rising clock edge (RR), falling clock edge to rising clock edge (FR), rising clock edge to falling clock edge (RF), and falling clock edge to falling clock edge (FF) paths.

- If a path exists in the design, the report column cell is white and lists the number of paths.
- If a path is a false path, the report column cell is light gray and contains the text "false path."
- If a path does not exist in the design, then the report column cell is dark gray.

The Setup Transfers report and Hold Transfers report also lists the Worst-Case Slack for setup, the Worst-Case Operating Conditions, and the Clock Pair Classification for each clock path. The Clock Pair Classification includes the following:

Table 26. Clock Pair Classifications

Clock Pair Classification	Definition
Intra-Clock (Timed Safe)	• From Clock and To Clock are the same. • No timing constraint required.
Inter-Clock Synchronous (Timed Safe)	• From Clock and To Clock relate synchronously, and have a known phase and frequency relationship. • Multicycle path constraint may or may not exist.
Asynchronous (Timed Unsafe)	• From Clock and To Clock are asynchronous. • Timing constraints (false path, clock groups, set_max_skew) do not exist.
Ignored (Not Timed)	• From Clock and To Clock are asynchronous. • Timing constraints (false path, clock groups, set_max_skew) exist and setup and hold slack are not applicable.

2.5.8. Report Metastability

The Timing Analyzer's **Reports ➤ Clock Domain Crossings ➤ Report Metastability...** command generates a list of synchronization register chains found in the design, and can provide estimates of the Mean Time Between Failures (MTBF) of each chain. The equivalent scripting command is `report_metastability`.

Metastable registers have outputs hovering at a voltage between high and low for a length of time beyond the normal t_{CO} for the register, which may cause subsequent registers that use this metastable signal to latch different values. Synchronize register chains when transferring data between unrelated clock domains to reduce the probability of the captured data signal becoming metastable.

A synchronization register chain is a sequence of registers with the same clock, that is driven by a pin, or logic from an unrelated clock domain. All but the last register in the chain must connect only to the next register, but may do so through logic.

The Metastability Report displays the following for each synchronization chain the analysis discovers:

- Typical Mean Time Between Failures (MTBF) for the chain
- MTBF equation and method of synchronizer identification
- Available settling time of the synchronization register chain
- Number of synchronization registers in the chain

- Names of synchronization registers in the chain
- name of asynchronous source registers
- Data toggle rate used in the MTBF estimation
- Source clock domain names
- Synchronization clock domain names

To help you analyze synchronizer chains in more detail, you can report the neighbor paths for synchronization registers in a chain. From the list of synchronization registers in the report in the Timing Analyzer GUI, you can right-click any of the synchronization register names an click **Report Neighbor Paths** in the context menu.

To report the timing for the synchronization registers, you can right-click and then click **Report Timing** for the synchronization registers. For the asynchronous source registers, right-click and click **Report Path**.

When you do not specify a data toggle rate, the Timing Analyzer uses the value of 12.5% of the frequency of the clock domain that contains the synchronizer to calculate MTBF.

Related Information

- Metastability Analysis on page 16
- Step 1: Specify General Timing Analyzer Settings on page 29

2.5.9. Report CDC Viewer

The Timing Analyzer's **Reports ➤ Clock Domain Crossings ➤ Report CDC Viewer...** command allows you to configure and display a custom clock domain crossing report and the Clock Domain Crossing (CDC) Viewer. The CDC Viewer graphically displays the setup, hold, recovery, or removal analysis of all clock transfers in your design. The equivalent scripting command is `report_cdc_viewer`.

Table 27. Report Clock Domain Crossing Viewer Settings

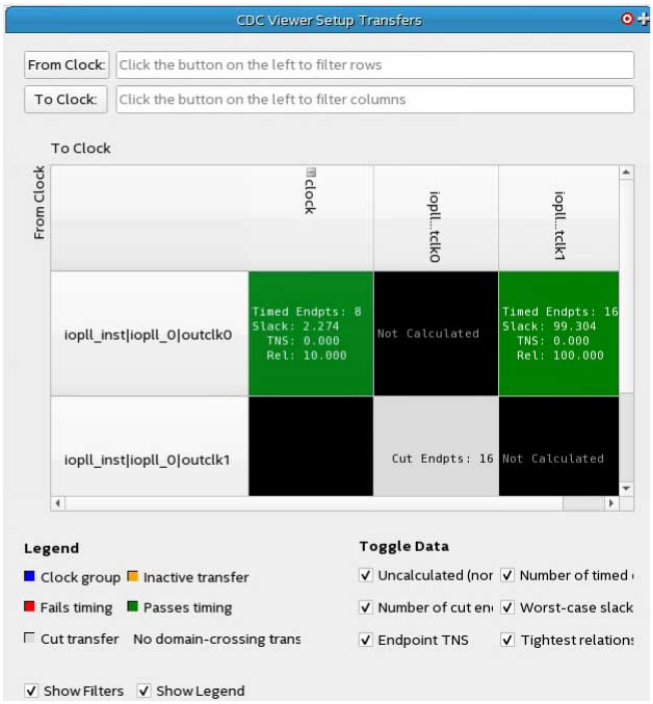
Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Analysis type	Options are **Setup**, **Hold**, **Recovery**, or **Removal**. The Timing Analyzer reports the results for the type of analysis you select.
Transfers	Specifies the type of clock transfers to include or exclude from the report, including **Timed transfers**, **Fully cut transfers**, **Clock groups, Inactive clocks**, and **Non-crossing transfers**. You can specify the **Maximum slack limit** and **Grid options** for the report.
Detail level	**Full** shows all details of the report and **Summary** filters the details and shows summary data.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data, and specify **Grid** or **List** format. *Note:* In grid format reports, clocks with non-crossing transfers always appear if they have transfers between other clocks.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

You can specify the following options to customize CDC Viewer reporting:

Table 28. CDC Viewer Report Controls

Control	Description
From Clock: and **To Clock:**	Filters the display according to the clock names you specify. Click **From Clock:** or **To Clock:** to search for specific clock names.
Legend	Defines the status colors. A color coded grid displays the clock transfer status. The clock headers list each clock with transfers in the design. The GUI truncates long clock names, but you can view the full name in a tool tip or by resizing the clock header cell. The GUI represents the generated clocks as children of the parent clock. A '+' icon next to a clock name indicates the presence of generated clocks. Clicking on the clock header displays the generated clocks associated with that clock.
Toggle Data	The text in each transfer cell contains data specific to each transfer. Turn on or off display of the following types of data: • **Number of timed endpoints** between clocks— the number of timed, endpoint-unique paths in the transfer. A path being "timed" means that analysis occurs on that path. Only paths with unique endpoints count towards this total. • **Number of cut endpoints** between clocks— the number of cut endpoint-unique paths, instead of timed paths. These paths are cut by either a false path or clock group assignment. Timing analysis skips such paths. • **Worst-case slack** between clocks— the worst-case slack among all endpoint-unique paths in the transfer. • **Total negative slack** between clocks— the sum of all negative slacks among all endpoint-unique paths in this transfer. • **Tightest relationship** between clocks— the lowest-value setup, hold, recovery, or removal relationship between the two clocks in this transfer.
Show Filters and **Show Legend**	Turns on or off Filters and **Legend**.

Figure 161. CDC Viewer Setup Transfers Report



Each block in the grid is a transfer cell. Each transfer cell uses color and text to display important details of the paths in the transfer. The color coding represents the following states:

Table 29. Transfer Cell Content

Cell Color	Color Legend
Black	Indicates no transfers. There are no paths crossing between the source and destination clock of this cell.
Green	Indicates passing timing. All timing paths in this transfer, that have not been cut, meet their timing requirements.
Red	Indicates failing timing. One or more of the timing paths in the transfer do not meet their timing requirements. If the transfer is between unrelated clocks, the paths likely require a synchronizer chain.
Blue	Indicates clock groups. The source and destination clocks of these transfers are cut by means of asynchronous clock groups.
Gray	Indicates a cut transfer. All paths in this transfer are cut by false paths. Therefore, timing analysis does not consider these paths.
Orange	Indicates inactive clocks. One of the clocks in the transfer is an inactive clock (with the `set_active_clocks` command). The Timing Analyzer ignores such transfers.

Right-click menus allow you to perform operations on transfer cells and clock headers. When the operation is a Timing Analyzer report or SDC command, a dialog box opens containing the contents of the transfer cell.

Table 30. Transfer Cell Right-Click Menus

Command	Description
Copy	Copies the contents of the transfer cell or clock header to the clipboard.
Report Timing	Reports timing. Not available for transfer cells with no valid paths (gray or black cells).
Report Endpoints	Reports endpoints. Not available for transfer cells with no cut paths (gray or black cells).
Report False Path	Reports false paths. Not available for transfer cells with no valid paths (black cells).
Report Exceptions	Reports exceptions. Only available for clock group transfers (blue cells).
Report Exceptions (with clock groups)	Reports exceptions with clock groups. Only available for clock group transfers (blue cells).
Set False Path	Sets a false path constraint.
Set Multicycle Path	Sets a multicycle path exception.
Set Min Delay	Sets a min delay constraint.
Set Max Delay	Sets a max delay constraint.
Set Clock Uncertainty	Sets a clock uncertainty constraint.

Table 31. Clock Header Right-Click Menus

Command	Description
Copy (include children)	Copies the name of the clock header, and the names of each of its derived clocks. This option only appears for clock headers with generated clocks.
Expand/Collapse All Rows/Columns	Shows or hides all derived clocks in the grid.

continued...

Command	Description
Create Slack Histogram	Generates a slack histogram report for the clock you select.
Report Timing From/To Clock	Generates a timing report for the clock you select. If you do not expand the clock to display derived clocks, the timing report includes all clocks that derive from the clock. To prevent this, expand the clock before right-clicking it.
Remove Clock(s)	Removes the clock you select from the design. If you do not expand the clock, timing analysis removes all clocks that derive from the clock.

You can view CDC Viewer output in any of the following formats:

- A report panel in the Timing Analyzer
- Output in the Timing Analyzer Tcl console
- A plain-text file
- An HTML file you can view in a web browser.

Related Information

- Constraining CDC Paths on page 92

2.5.10. Report Asynchronous CDC

The Timing Analyzer's **Reports ➤ Clock Domain Crossings ➤ Report Asynchronous CDC...** command allows you to classify and report all asynchronous clock-domain-crossing (CDC) transfers in your design. Asynchronous CDCs include single-bit transfers, multibit transfers, and asynchronous reset CDCs. Designs often contain unintended CDCs or transfers. Use this report to ensure that the Timing Analyzer correctly detects all CDCs.

Table 32. Report Asynchronous CDC Information Settings

Option	Available Settings
Clocks	Filters the report to only show CDCs that originate from **From clock** and terminate at **To clock**.
Targets	Filters the report to only show CDCs that originate from **From** register and terminate at **To** register. Both the **From** and **To** must be registers. This option is optional with the **Clocks** option.
Entries	Limits the number of entries that are reported per CDC category
Detail	Chooses whether to show a summary of all CDC's or give detail on each individual CDC
CDC Categories	Specifies the CDC categories to be reported.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can overwrite or append the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

Figure 162. Report Asynchronous CDC Summary View

Asynchronous CDC Summary

1	Unsynchronized Reset Synchronizer	1	1
2	Unconstrained Reset Synchronizer	1	1
3	Reset Synchroniz...Multiple Sources	1	1
4	Inactive Reset Synchronizer	1	1

The summary view of the Asynchronous CDC Report provides an overview of the number of CDC's that fall into each category in your design. CDC Count gives the number of topologies detected for a category. **Total Transfer Width** shows the total number of CDC crossings for a category. This value is different than **CDC Count** for multibit CDC's because each topology consists of multiple crossings.

The full view of the Asynchronous CDC report shows the source and destination registers and clocks for each detected CDC topology in your design. You may click on any row of this report. Clicking on a row that contains the name of a CDC category brings up the description for that category and associated Design Assistant rules that check for such topologies. Clicking on a row that contains a CDC displays detailed information on that CDC in the **CDC Statistics** table. The information available varies depending on the topology of the CDC.

1	dataOut[91]	
9	Chain Length Protected	1
10	Protecting less synchron...than discovered because:	
1	The synchronizer regis...mode is set to FORCED:	
1	logic_within_forced_chain|synch_reg1	

In the Asynchronous CDC Full Report panel, the All Source Clocks (Synch/Asynch) column displays all clocks driving all source nodes of a synchronizer chain, regardless of whether the transfers are synchronous or asynchronous. There can be asynchronous and synchronous transfers into the head of a synchronizer chain if the paths go through combinational logic before the head of the synchronizer chain. For example, Figure xx shows a circuit with both asynchronous and synchronous transfers

into a synchronizer chain. For this example, the Asynchronous CDC Full Report lists both `clkA` and `clkB` as source clocks of the synchronizer chain, even though `clkB` is a synchronous transfer.

Figure 165. Circuit with Asynchronous and Synchronous Transfers to a Synchronizer Chain

2.5.11. Report Logic Depth

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Logic Depth...** command allows you to report the number of logic levels within a clock domain. This value typically corresponds to the number of look-up tables (LUTs) that a path passes through.

The equivalent scripting command is `report_design_metrics -logic_depth`. **Report Logic Depth** shows the distribution of logic depth among the critical paths, allowing you to identify areas where you can reduce logic levels in your RTL.

Figure 166. Report Logic Depth (Histogram)

Figure 167. Report Paths of Depth 3

Call report logic depth by topology for each clock, intraclock only.

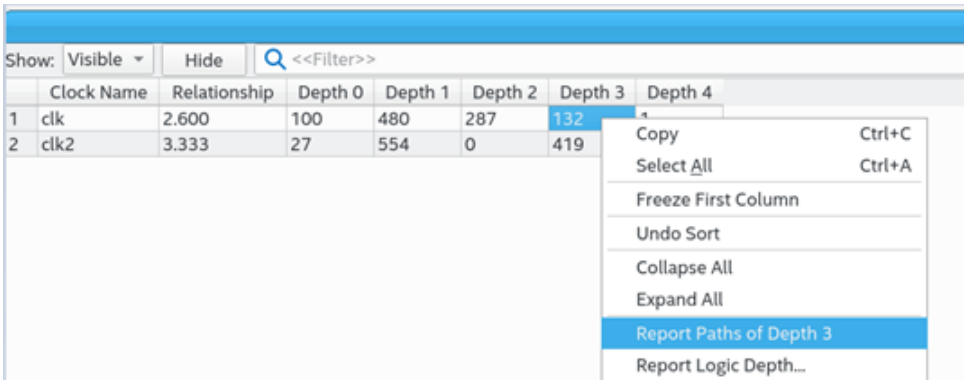

Figure 168. Summary of Paths

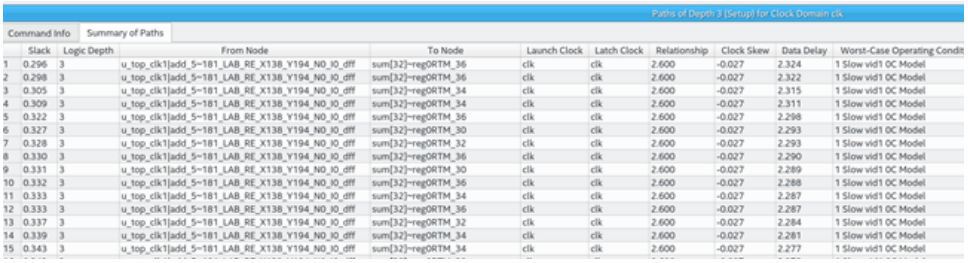
Close timing with accurate histogram cross probing.



You can specify various options to customize the reporting.

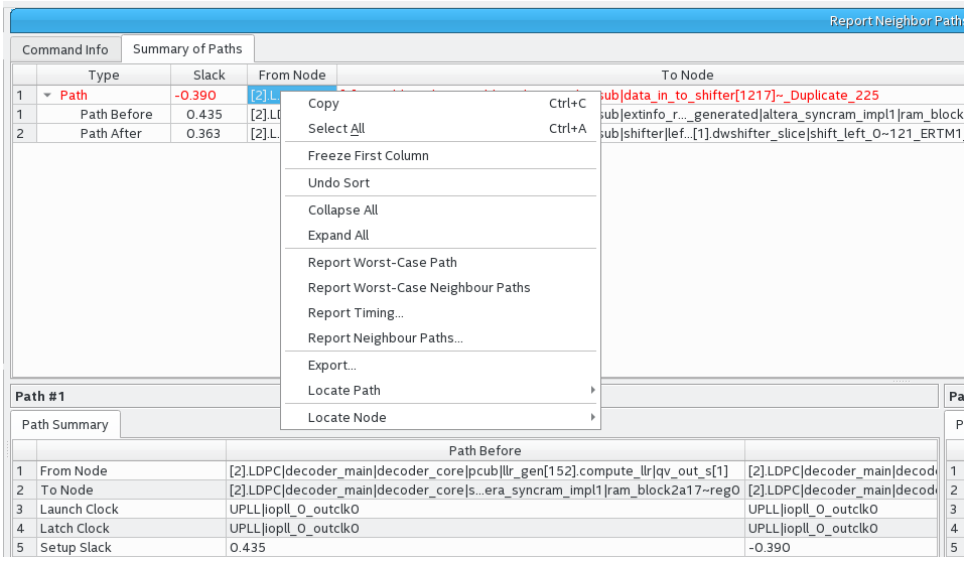
Table 33. Report Logic Depth Settings

Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Targets	Specifies the target node for **From Clock** and **To Clock** to report logic depth with only those endpoints. Specify an I/O or register name or I/O port for this option. The field also supports wildcard characters. When the **From**, **To**, or **Through** boxes are empty, the Timing Analyzer assumes all possible targets in the device. The **Through** option limits the report for paths that pass through combinatorial logic, or a particular pin on a cell.
Analysis type	The **Setup**, **Hold**, **Recovery**, and **Removal** analyses report the logic depths of the top *X* paths by slack. **Topology** analysis reports the logic depths of the top *X* paths by logic depth.
Paths	Specifies the number of paths to display by endpoint and slack level. The default value for **Report number of paths** is 10, otherwise, the report can be very long. Enable **Pairs only** to list only one path for each pair of source and destination. Limit further with **Maximum number of paths per endpoints**. You can also filter paths by entering a value in the **Maximum slack limit** field.
Detail	Specify whether to display on **Histogram** or full **Path** level of detail.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

2.5.12. Report Neighbor Paths

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Neighbor Paths...** command helps you to determine the root cause of critical paths (for example, high logic level, retiming limitation, sub-optimal placement, I/O column crossing, hold fix-up, time borrowing, or others). The equivalent scripting command is `report_design_metrics -neighbor_paths`.

Figure 169. Report Neighbor Paths Report



Report Neighbor Paths reports the most timing-critical paths in the design, including associated slack, additional path summary information, and path bounding boxes. **Report Neighbor Paths** shows the most timing-critical **Path Before** and **Path After** each critical **Path**. You can optionally view multiple before and after paths. Retiming or logic balancing of the **Path** can simplify timing closure if there is negative slack on the **Path**, but positive slack on the **Path Before** or **Path After**.

Table 34. Report Neighbor Path Dialog Box Settings

Option	Description
Clocks	**From Clock** and **To Clock** filter paths in the report to show only the launching or latching clocks you specify.
Targets	Specifies the target node for **From Clock** and **To Clock** to report neighbor paths with only those endpoints. Specify an I/O or register name or I/O port for this option. The field also supports wildcard characters. When the **From**, **To**, or **Through** boxes are empty, the Timing Analyzer assumes all possible targets in the device. The **Through** option limits the report for paths that pass through combinatorial logic, or a particular pin on a cell.
Analysis type	The **Analysis type** options are **Setup**, **Hold**, **Recovery**, or **Removal**. The Timing Analyzer reports the results for the type of analysis you select.
Paths	Specifies the number of paths to display by endpoint and slack level. The default value for **Report number of paths** is 10, otherwise, the report can be very long. Enable **Pairs only** to list only one path for each pair of source and destination. Limit further with **Maximum number of paths per endpoints**. You can also filter paths by entering a value in the **Maximum slack limit** field.

continued...

Option	Description
Report Number of Neighbor Paths	Specifies the number of neighbor paths to report, allowing you to view a number of the top adjacent paths entering the critical path, and the top paths exiting the critical path.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.
Extra Info	Specifies extra info.

2.5.13. Report Register Spread

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Register Spread...** command analyzes the final placement to identify registers with sinks pulling them in various directions. These registers are potential candidates for duplication. The equivalent scripting command is `report_register_spread`.

Registers that drive in opposite directions and connect to high fan-out can have placement-warping effects on the floorplan that impact f_{MAX}. The placement-warping may not cause timing failures. Therefore, you can view this report to identify such registers. Taking steps to address the registers listed in the report can make placement of the design easier and improve f_{MAX} performance.

You can automate duplication of registers with the `DUPLICATE_REGISTER` and `DUPLICATE_HIERARCHY_DEPTH` `.qsf` assignments, or you can manually modify RTL to duplicate registers or refactor logic. Refer to "Automatic Register Duplication: Hierarchical Proximity" in *Quartus Prime Pro Edition User Guide: Design Optimization*.

Figure 170. Report Register Spread Report

Report Register Spread

Show: Visible | Hide | <<Filter>>

Register Name	Register_Location	Number of Endpoints	Endpoint Centroid	Total Distance of Endpoints
counter_a[0]~ERTM	(69, 67)	78	(69, 67)	117.0
counter_a[1]~ERTM	(68, 67)	39	(68, 66)	21.4
counter_b[1]~ERTM	(70, 67)	39	(70, 67)	21.4
counter_b[2]~ERTM	(70, 67)	38	(70, 67)	20.9
counter_a[2]~ERTM	(68, 67)	38	(68, 66)	20.9
counter_b[3]~ERTM	(70, 67)	37	(70, 66)	20.4

You can specify various options to customize the report.

Table 35. Report Register Spread Settings

Option	Available Settings
Spread Type	Specifies the type of spread data in the report:

continued...

Option	Available Settings
	• **Tension**—reports the sum over each sink of the distance from it to the centroid of all the sinks. • **Angle**—reports how far around the source register the fan-outs wrap, expressed from 0 to 360 degrees. This value corresponds to 360 minus the maximum angle between any two angularly adjacent sinks. This metric complements **Tension** by identifying registers which are surrounded by their sinks in all directions, and not those registers only being pulled in a few directions. • **Span**—reports the maximum 1-dimensional delta between the left bottom-most sink and the right top-most sink. • **Area**—reports the coverage of the sinks by number of LABs on the FPGA device. This option multiplies the span of the sinks in both X- and Y- dimensions. This metric complements **Span** by incorporating both dimensional spans of the sinks, and not only the maximum sink. • **Count**—reports registers with the largest sink counts.
Sink Type	Specifies the type of sink in the report: • **Endpoint**—the nodes (usually registers) that terminate timing paths from a register. • **Immediate Fanout**—the immediately connected nodes of the register. For example, lookup tables, other registers, RAM, or DSP blocks.
From Clock	Filters paths in the report to show only the launching clocks you specify.
To Clock	Filters paths in the report to show only the latching clocks you specify, allowing you to debug one clock at a time.
Report number of registers	Specifies the number of registers to display in the report. The default value for **Report number of registers** is 10.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

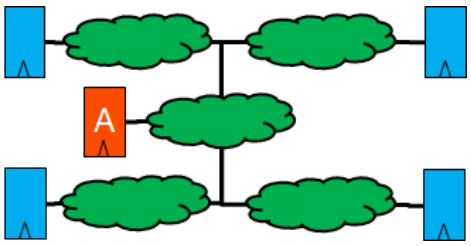
Automatic Register Duplication: Hierarchical Proximity, Quartus Prime Pro Edition

2.5.13.1. Registers with High Timing Path Endpoint Tension

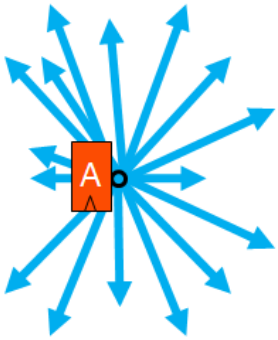
Timing path endpoints are the nodes (usually registers) that terminate timing paths from a register. The Timing path endpoint is equivalent to the nodes that the `get_fanouts` command returns, or the overall set of nodes that appear as a "From Node" after running the `report_timing` command. Register duplication is necessary, but not always sufficient, in helping to distribute the signal more efficiently. In addition, you may need to duplicate or restructure any intermediate logic before duplicating the register.

Figure 173. Register A has 4 Timing Path Endpoints



Tension is the sum over each sink of the distance from the sink to the centroid of all the sinks. The value of tension is therefore dependent on the number of sinks. Register duplication can help to break up these clouds, since they may be the result of the placement solution getting "warped" by the presence of the register.

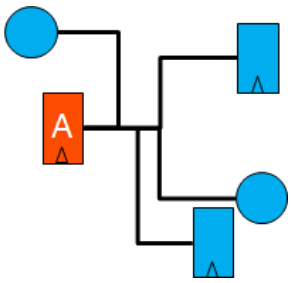
Figure 174. Register A has High Tension



2.5.13.2. Registers with High Immediate Fan-Out Tension

There are two **Sink Type** options: **Endpoint** and **Immediate Fanout**. The immediate fan-outs are the immediately connected nodes (lookup tables, other registers, RAM or DSP blocks, and others) of the register. This fan-out is equivalent to fan-outs that the Chip Planner displays, and in various high fan-out reports. Register duplication directly distributes the immediate fan-outs of a register among the duplicates.

Figure 175. Register A has High Immediate Fan-Out



2.5.14. Report Route Net of Interest

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Route Net of Interest...** command allows you to report the nets that require the most effort from the router. The report shows the percentage of total router effort for the nets reported. The equivalent scripting command is `report_route_net_of_interest`.

This report allows you to identify nets that should not require significant router effort. For example, you might expect that low speed management interface nets are not timing critical, and therefore not require much router effort. However, if **Report Route Net of Interest** reports that some nets in the low speed management interface require significant effort from the router, you can investigate that further. The investigation can determine whether the timing constraints are correct, whether the fan-out is significant and can reduce through driver duplication, or whether the net passes through congested areas.

Figure 176. Report Route Net of Interest Report

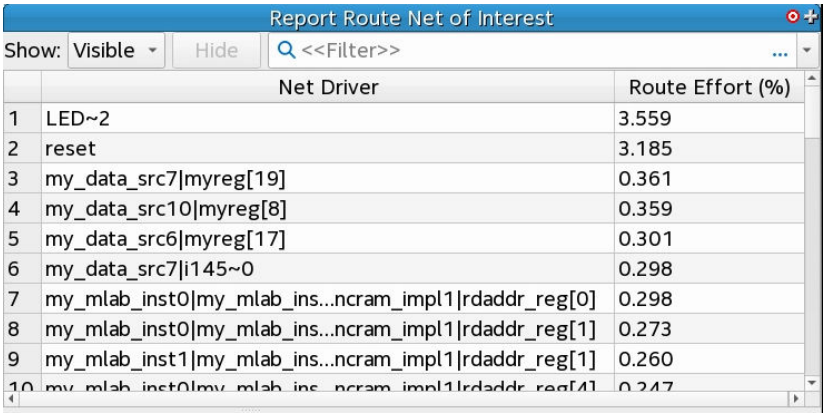


Figure 177. Report Route Net of Interest Dialog Box

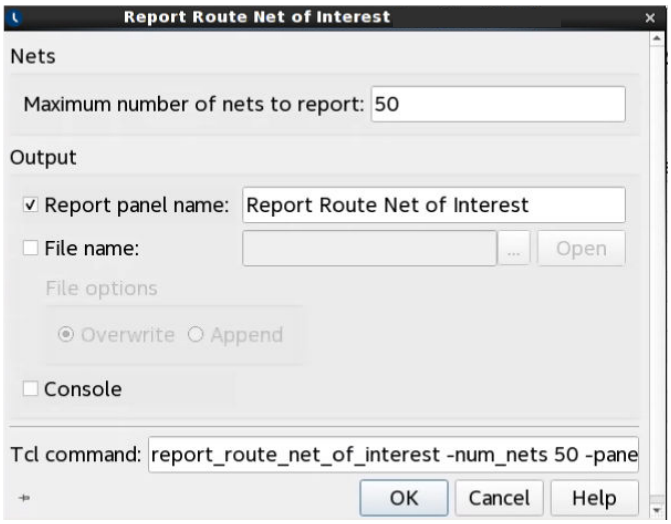

From the Route Net of Interest Report in the Timing Analyzer GUI, you can right-click on any net and run Report Timing for more details about the net, its slack, and any of the net's paths.

Table 36. Report Route Net of Interest Settings

Option	Available Settings
Nets	Specifies the **Maximum number of nets to report**. The default value is 50.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

2.5.15. Report Retiming Restrictions

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Retiming Restrictions...** command allows you to report the occurrences of design conditions that restrict Hyper-Retiming, such as Power-up "Care" restrictions, and don't touch or preserve attributes for each port. You can refer to this report to improve the circuit and remove retiming restrictions that limit circuit performance. `report_retiming_restrictions` is the equivalent scripting command.

Figure 178. Report Retiming Restrictions Report

Report Retiming Restrictions

<<Filter>>

	Compilation Hierarchy Node	Register is part of a synchronization chain	Preserve assignn
1	|	114 (0)	292 (50)
1	|my_data_src7|	21 (21)	0 (0)
1	|myreg[*]	20 (20)	0 (0)
2	|enable_reg	1 (1)	0 (0)
2	|my_data_src8|	21 (21)	0 (0)
1	|myreg[*]	20 (20)	0 (0)
2	|enable_reg	1 (1)	0 (0)
3	|my_data_src5|	19 (19)	0 (0)
1	|myreg[*]	18 (18)	0 (0)
2	|enable_reg	1 (1)	0 (0)
4	|my_data_src6|	19 (19)	0 (0)

Note: For table entries with two numbers listed, the numbers in parentheses indicate the number of retiming restrictions in the specific entity alone. The numbers listed outside of parentheses indicate the number of retiming restrictions in the specific entity and all of its sub-entities in the hierarchy.

For table entries with two number values, the number in parentheses indicates the number of retiming restrictions in the specific entity alone. The number listed outside of parentheses indicates the number of retiming restrictions in the specific entity and all of its sub-entities in the `hierarchy`.

2.5.16. Report Register Statistics

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Register Statistics** command allows you to report the number of synchronous and asynchronous resets, hyper registers, and registers with clock enables in the design. You can use this information, combined with timing slack, congestion, and other analysis reports, to identify timing-critical parts of your design that can have resets removed or control schemes changed to meet timing requirements more efficiently.

Figure 179. Report Register Statistics (Report Truncated)

Report Register Statistics

<<Filter>> (use !<string> to invert filter)

	Compilation Hierarchy Node	Register Count	Without a Clock	Unique Clocks	Hyper-Register Count	Synchronous Reset	Asynchronous Reset
1	|	3645 (0)	0 (0)	2 (0)	0 (0)	311 (0)	777 (0)
1	|auto_fab_0|	88 (0)	0 (0)	1 (0)	0 (0)	7 (0)	38 (0)
1	|alt_sld_fab_0|	88 (0)	0 (0)	1 (0)	0 (0)	7 (0)	38 (0)
2	|intel_niosv_m_0|	2789 (0)	0 (0)	2 (0)	0 (0)	235 (0)	658 (0)

Truncated Report Columns:

Clock Enable	Synchronous Load	Without a Control Signal	Full Hierarchy Name
2472 (0)	0 (0)	726 (0)	|
63 (0)	0 (0)	12 (0)	auto_fab_0
63 (0)	0 (0)	12 (0)	auto_fab...ld_fab_0
1961 (0)	0 (0)	454 (0)	intel_niosv_m_0

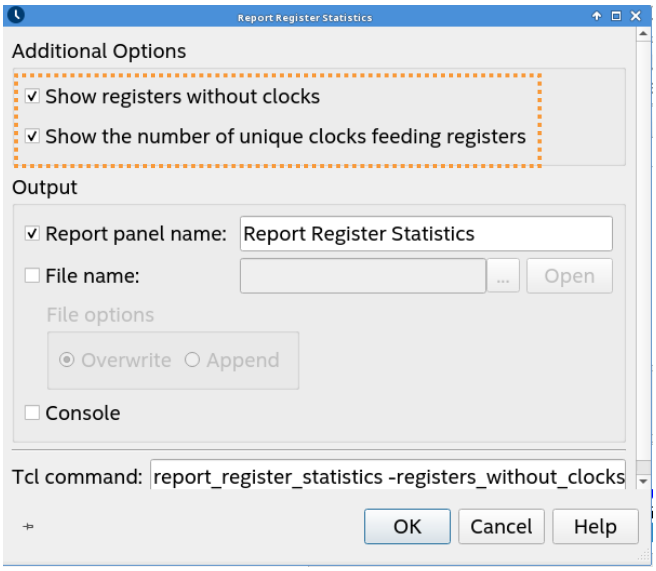
Note:

- This report works similarly in both post-synthesis Early Timing Analysis and post-fit timing analysis. However, the report's **Without a Clock** column is more helpful for Early Timing Analysis because you typically do not apply conventional SDCs for Early Timing Analysis.
- Clocks generated from `derive_clocks` commands do not count as user clocks.
- The report's **Without a Control Signal** column identifies registers that have no corresponding control signal.
- The report's **Synchronous Load** column identifies any synchronous load that can apply to Arria 10 devices only.

The **Without a Clock** column informs you of the number of registers where no defined clock feeds the registers in the hierarchy shown in the **Register Count** column. A value of 0 in this column suggests that your design has SDC-defined clocks feeding registers in the design. The **Unique Clocks** column indicates the number of unique SDC-defined clocks feeding registers in the hierarchy identified by the

Register Count. To view these columns, enable **Show registers without clocks** and **Show the number of unique clocks feeding registers** additional options in the dialog that displays when you run the report, as shown in the following image:

Figure 180. Report Register Statistics Additional Options Dialog



2.5.17. Report Pipelining Information

The Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Pipelining Information...** command allows you to generate a report that can help you to identify potential areas of over-pipelining in your design. Excessive pipelining unnecessarily consumes area. The equivalent scripting command is `report_pipelining_info`.

Report Pipelining Information... does not perform any functional analysis in making the recommended pipeline stage adjustment. You must be aware of any potential functional changes from removing pipeline stages. There may be circumstances when all the stages in a register pipeline are necessary for functional reasons. The report helps to identify location with more registers than necessary for covering distance.

21	final_dat[0]~reg0	2.855	0	1

To help identify potential over-pipelining, **Report Pipelining Information** reports:

- The recommended pipeline stage adjustment across bus
- The minimum total slack of one bit across bus
- The minimum average slack of one bit across bus
- The distance between the registers
- The width of buses in your design
- The number of sequential registers
- The number of registers on the bus

The Recommended Pipeline Stage Adjustment Across Bus reports the number of registers that you can remove from the bus for each bit. The Average Distance Per Stage, Max Distance Per Stage, and Min Distance Per Stage columns report the Manhattan distance measured in logic array blocks (LABs). The Bus Average Depth, Bus Max Depth, and Bus Min Depth columns report the number of sequential, single fan-out registers. For registers that have more than one clock source, the report lists the fastest one.

The **1+** sign under Recommended Pipeline Stage Adjustment Across Bus column means that the bus might need to add more registers to meet timing requirement. Refer to the Fast Forward Timing Closure Recommendations report.

If the report identifies a large register chain with multiple sequential registers, and the distance between registers is low, that condition can suggest over-pipelining. You may be able to remove some registers to recover some of the device area and reduce congestion.

The following options are available for this report:

Figure 184. Report Pipelining Information Dialog Box

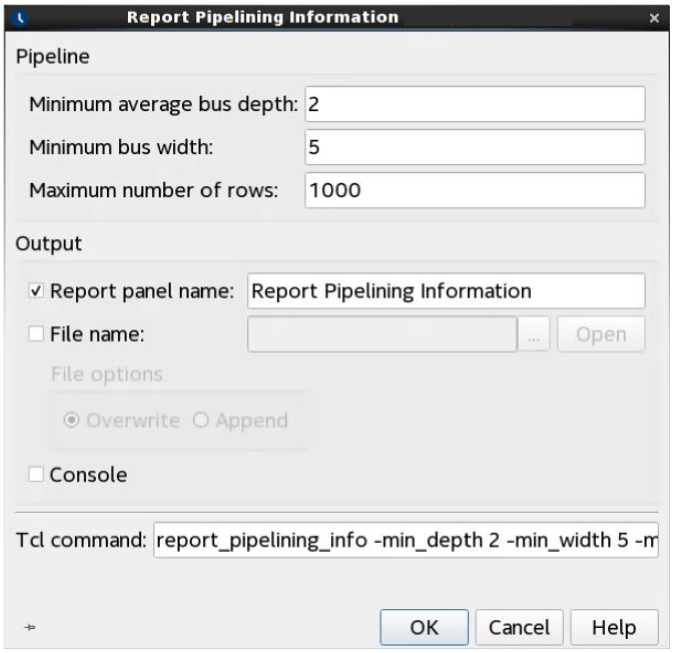

Table 37. Report Pipelining Information Settings

Option	Available Settings
Pipeline	Specifies the thresholds for reporting a register pipeline. You can define the **Minimum average bus depth**, the **Minimum bus width**, and the **Maximum number of rows** that the report includes.
Report panel name	Specifies the name of the report panel. You can optionally enable **File name** to write the information to a file. If you append `.htm` or `.html` as a suffix, the Timing Analyzer produces the report as HTML. If you enable **File name**, you can **Overwrite** or **Append** the file with latest data.
Tcl command	Displays the Tcl syntax that corresponds with the GUI options you select. You can copy the command from the **Console** into a Tcl file.

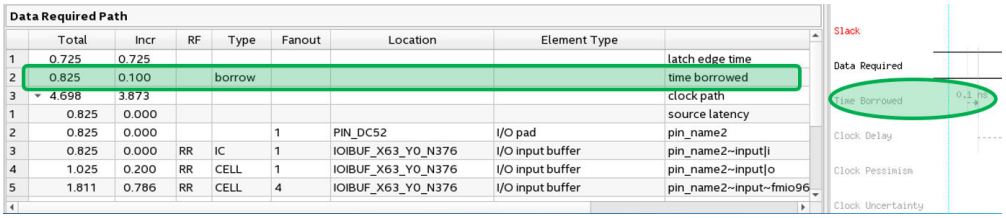
2.5.18. Report Time Borrowing Data

You can run the Timing Analyzer's **Reports ➤ Timing Slack ➤ Report Timing...** command to generate a report showing time borrowing data. The equivalent scripting command is `report_timing` (with specific arguments).

The Timing Analyzer reports time borrowing data for the **Data Arrival Path** or **Data Required Path**, according to whether borrowing occurs at the destination or the source.

Figure 185. Report for Time Borrowing At Destination

The following report shows 100ps borrowed on the Data Required path. The setup slack improves on incoming paths, at the expense of worse setup slack for outgoing paths.



Data Required Path

	Total	Incr	RF	Type	Fanout	Location	Element Type	
1	0.725	0.725						latch edge time
2	0.825	0.100		borrow				time borrowed
3	4.698	3.873						clock path
1	0.825	0.000						source latency
2	0.825	0.000			1	PIN_DC52	I/O pad	pin_name2
3	0.825	0.000	RR	IC	1	IOIBUF_X63_Y0_N376	I/O input buffer	pin_name2~input|i

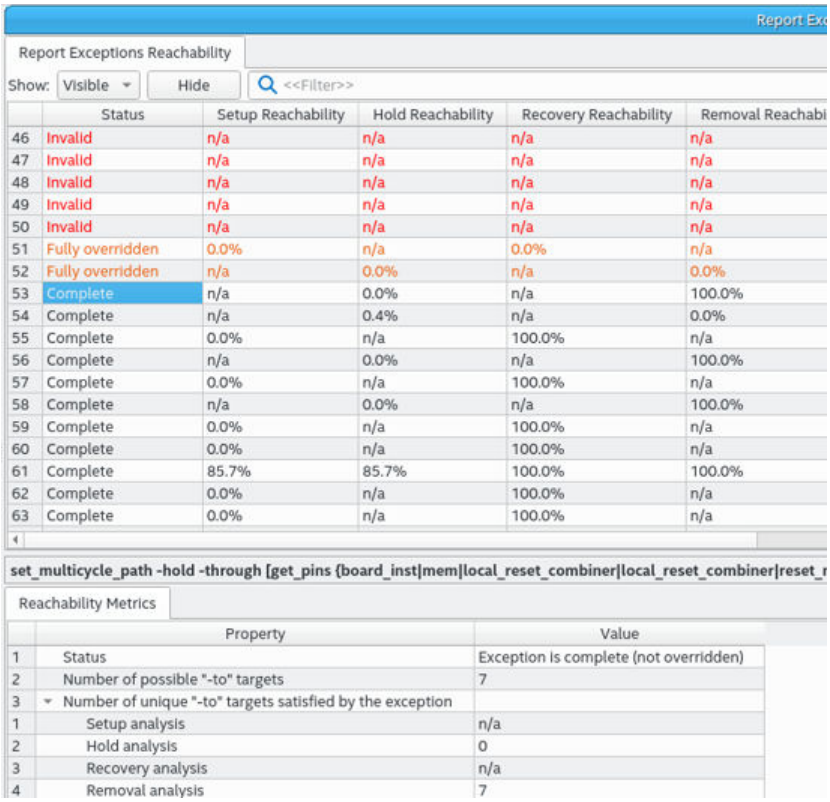
Time Borrowing on page 19

2.5.19. Report Exceptions and Exceptions Reachability

The Timing Analyzer's **Reports ➤ Constraint Diagnostics ➤ Report Exceptions...** command allows you to report all exceptions to default timing analysis conditions, as specified by the **Set False Path**, **Set Multicycle Path**, **Set Minimum Delay**, or **Set Maximum Delay** commands (and the corresponding Tcl commands: `set_false_path`, `set_multicycle_path`, `set_min_delay`, and `set_max_delay`.)

Figure 187. Report Exceptions Reachability Report



Similarly, you can click on **Reports ➤ Constraint Diagnostics ➤ Report Exceptions Reachability...** to report the scope of exception constraints in your project. This report allows you to determine whether constraints apply fully or partially, are overridden, and whether the source and destination node are reachable for the constraint by providing a "reachability" percentage. Reachability is the percentage of paths to which the constraint applies. Low reachability indicates a constraint that may be too broad, potentially covering many unrelated items. High reachability indicates that the exception is very targeted.

2.5.20. Report Bottlenecks

You can run the Timing Analyzer's **Reports ➤ Design Metrics ➤ Report Bottlenecks...** command to list all nodes in a design ranked by specified criteria. The equivalent scripting command is `report_bottleneck`.

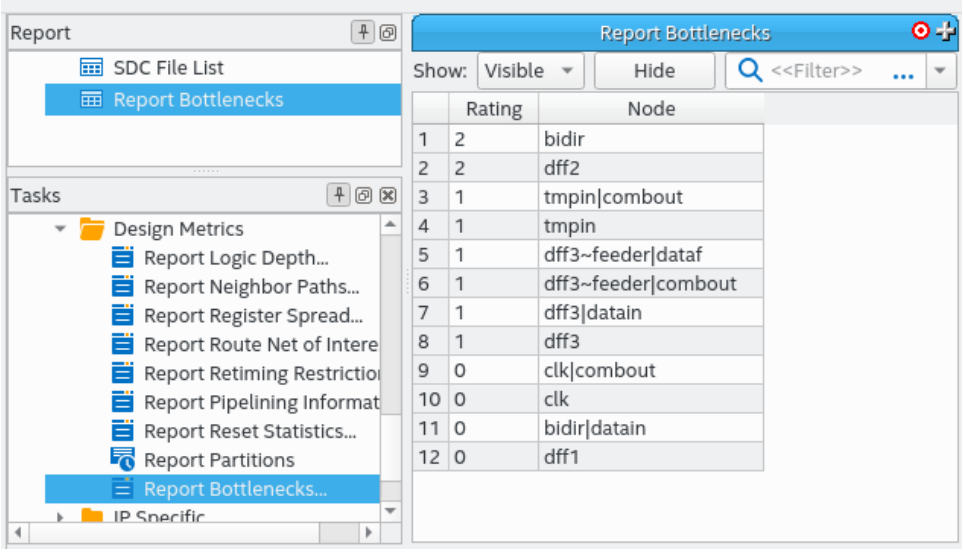
The following ranking criteria are pre-defined:

- `num_fpaths`—the number of paths that fail timing through a node.
- `num_fanins`—the number of fan-in edges from a node.
- `num_fanouts`—the number of fan-out edges from a node.
- `num_paths`—the number of paths through a node.
- `tns`—the total negative slack of all the paths through a node.

When using scripting, you can specify the paths for analysis by passing the result of any `get_timing_paths` call as the last argument to `report_bottleneck`. When using the GUI, the **Report Bottlenecks** dialog box handles this argument automatically. If you specify no paths, `report_bottleneck` analyzes the worst 1000 setup paths in the design by default.

You can direct the report output to the Tcl console (`-stdout`), the Timing Analyzer GUI (`-panel`), or to a combination of console and GUI.

Figure 188. Report Bottlenecks Rated on Number of Failing Paths Through a Node



2.5.20.1. Specifying Custom Bottleneck Criteria

You can optionally specify your own custom criteria for evaluating nodes based on the combination of the number of fan-outs, fan-ins, failing paths, and total paths.

To specify custom bottleneck criteria, follow these steps:

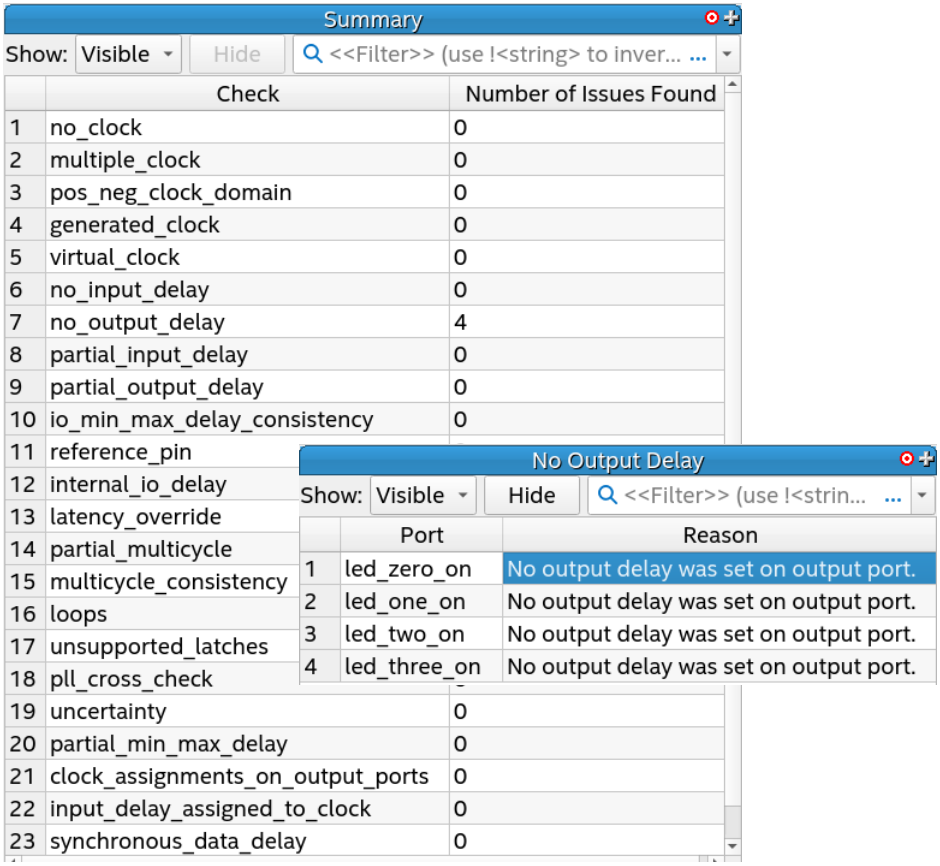
1. Create a Tcl procedure that takes one argument. For example, `arg`.
2. Use `upvar $arg metric` in the procedure.
3. Calculate the rating based on `$metric(tns)`, `$metric(num_fanouts)`, `$metric(num_fanins)`, and `$metric(num_fpaths)`.
4. Return the rating with `return $rating`.
5. Pass the name of your custom criteria procedure to `report_bottleneck` using the `-cmetric` option

2.5.21. Check Timing

The Timing Analyzer's **Reports ➤ Constraint Diagnostics ➤ Check Timing** command (`check_timing`) checks your design and constraint files for problems with design constraints.

Check Timing can perform a series of different checks based on the variables and options that you specify for the command. When using scripted methods, use the `-include` option to specify which checks to perform. You must run **Update Timing Netlist** (`update_timing_netlist`) before running **Check Timing** (`check_timing`).

Figure 189. Check Timing Report and No Output Delay Subreport



Check Timing can report the following data:

Table 38. Check Timing Report Data

Check Timing Data	Description
no_clock	Reports the registers that do not have at least one clock assignment at their clock pin, including any PLLs without a clock assignment.
multiple_clock	Reports the registers that have more than one clock at their clock pin. If multiple clocks reach a register clock pin, you must define which clock is used for analysis.
generated_clock	Reports the generated clocks that are invalid. Generated clocks must have a source that is triggered by a valid clock.
no_input_delay	Reports the input ports that are not clocks that have no input delay constraint.
no_output_delay	Reports the output ports that have no output delay constraint.

continued...

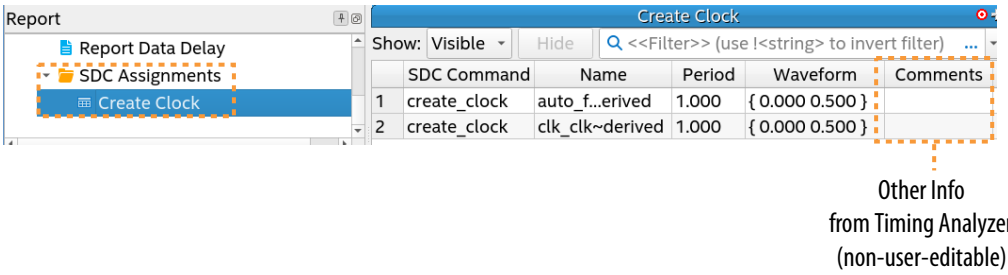
Check Timing Data	Description
partial_input_delay	Reports the input delays that lack a `rise-min`, `fall-min`, `rise-max`, and `fall-max` constraint set.
partial_output_delay	Reports the output delays that lack a `rise-min`, `fall-min`, `rise-max`, and `fall-max` constraint set.
io_min_max_delay_consistency	Reports the minimum delay values that you specify in `set_input_delay` or `set_output_delay` constraints that are not less than maximum delay values.
reference_pin	Reports the reference pins that you specify with `set_input_delay` and `set_output_delay` using the `-reference_pin` that are invalid. A `reference_pin` is only valid if the `-clock` option in the same `set_input_delay` or `set_output_delay` command matches the clock that is in the direct fan-in of the `reference_pin`. Being in the direct fan-in of the `reference_pin` means that there must be no keepers between the clock and the `reference_pin`.
latency_override	Reports the instances where the clock latency that you set on a port or pin overrides the more generic clock latency set on a clock. You can set clock latency on a clock, where the latency applies to all keepers clocked by the clock. You can also set clock latency on a port or pin, where the latency applies to registers in the fan-out of the port or pin.
loops	Reports the instances where there are strongly connected components in the netlist. These loops prevent a design from properly analysis. The loops check also reports whether loops exist but are marked so that they are not traversed by timing analysis.
latches	Reports the instances where latches are present in the design and warns that latches may not be analyzed properly. For best results, change your design to remove latches whenever possible.
pos_neg_clock_domain	Reports the instances where any register is clocked by both the rising and falling edges of the same clock. If this scenario is necessary, such as in a clock multiplexer, create two separate clocks that have similar settings and are assigned to the same node.
pll_cross_check	Reports the instances where clocks that are assigned to a PLL do not correspond properly with the PLL settings you define in design files. The subreport specifies the inconsistent settings, or an unmatched number of clocks associated with the PLL.
uncertainty	Reports the clock-to-clock transfers that do not have a clock uncertainty assignment set between the two clocks. If the target device family has `derive_clock_uncertainty` support, this report also includes the number of user-defined `set_clock_uncertainty` assignments that have less than recommended clock uncertainty value.
virtual_clock	Reports the unreferenced virtual clocks without constraint.
partial_multicycle	Reports the setup multicycle assignments without a corresponding hold multicycle assignment, and whether each hold muticycle assignment has a corresponding setup multicycle assignment.
multicycle_consistency	Reports the multicycle instances where a setup multicycle does not equal one less than the hold multicycle. Appropriate Hold multicycle assignments are usually one cycle less than setup multicycle assignments.
partial_min_max_delay	Reports the minimum delay assignments without a corresponding maximum delay assignment, and vice versa.
clock_assignments_on_output_ports	Reports the output ports that have clock assignments.
input_delay_assigned_to_clock	Reports the clocks with input delay values set. The Timing Analyzer ignores input delays set on clock ports because clock-as-data analysis takes precedence.
internal_io_delay	Reports the I/O delay constraints that have no specification for `-reference_pin` and `-source_latency_included`, and where `-clock` is a clock that is not assigned to a top level input or output port.

2.5.22. Report SDC

The Timing Analyzer's **Reports ➤ Constraint Diagnostics ➤ Report SDC** command generates the **SDC Assignments** report folder.

The **SDC Assignments** folder contains separately named reports for any SDC constraints found in the current project. For example, the Create Clock report appears in the **SDC Assignments** folder if the project includes any `create_clock` SDC constraint.

Figure 190. Create Clock Report Lists Clock Constraints in Current Project



In **SDC Assignment** reports, the **Comments** column may contain non-user-editable information reported by the Timing Analyzer.

Note: The **Comments** column in the **SDC Assignment** report has no relation to the SDC-on-RTL `-comment` argument that allows you to add comments to `.sdc` constraints. The SDC-on-RTL `-comment` does not appear in **SDC Assignment** reports.

The equivalent scripting command for **SDC Assignments** is `report_sdc`, for example:

```
report_sdc -panel_name sdc_report_panel
```

You can use the `-ignored` option to report any SDC constraints that the Timing Analyzer is ignoring and the reason for ignoring the constraint.

2.6. Scripting Timing Analysis

You can optionally use Tcl commands from the Quartus Prime software Tcl Application Programming Interface (API) to constrain, analyze, and collect timing information for your design. This section describes running the Timing Analyzer and setting constraints using Tcl commands. You can alternatively perform these same functions in the Timing Analyzer GUI. Tcl `.sdc` extensions provide additional methods for controlling timing analysis and reporting. The following Tcl packages support the Tcl timing analysis commands this chapter describes:

- `::quartus::sta`
- `::quartus::sdc`
- `::quartus::sdc_ext`

The Quartus Prime software provides the following two executables you can use for timing analysis and reporting:

- The `quartus_sta` executable—can perform timing analysis of your design without running the full Quartus Prime software GUI. If you use separate executables for various stages of design compilation (for example, `quartus_syn`, `quartus_fit`) you must use then use the `quartus_sta` executable to analyze timing for your placed and routed design. The `quartus_sta` executable also supports the interactive command-shell text-based timing reporting or scripted report generation.
- The `quartus_staw` executable—opens a GUI and supports interactive, graphical timing analysis and reporting.

Related Information

- ::quartus::sta
- ::quartus::staw
- ::quartus::sdc
- ::quartus::sdc_ext

2.6.1. The quartus_sta Executable

The `quartus_sta` executable allows you to run timing analysis without running the full Quartus Prime software GUI. The following methods are available:

- To run the Timing Analyzer in interactive command-shell mode, type the following at the command prompt:

```
quartus_sta -s
```

- To run timing analysis from a system command prompt, type the following command:

```
quartus_sta <options><project_name>
```

You can optionally use command line options available to perform iterative timing analysis on large designs. You can perform a less intensive analysis with `quartus_sta --mode=implement`. In this mode, the Quartus Prime software performs a reduced-corner timing analysis. When you achieve the desired result, you can use `quartus_sta --mode=finalize` to perform final Fitter optimizations and a full multi-corner timing analysis under all operating conditions.

Table 39. quartus_sta Command-Line Options

Command-Line Option	Description
`-h | --help`	Provides help information on `quartus_sta`.
`-t <script file> | --script=<script file>`	Sources the *<script file>*.
`-s | --shell`	Enters shell mode.
`--tcl_eval <tcl command>`	Evaluates the Tcl command *<tcl command>*.

continued...

Command-Line Option	Description
`--do_report_timing`	For all clocks in the design, run the following commands: `report_timing -npaths 1 -to_clock $clock` `report_timing -setup -npaths 1 -to_clock $clock` `report_timing -hold -npaths 1 -to_clock $clock` `report_timing -recovery -npaths 1 -to_clock $clock` `report_timing -removal -npaths 1 -to_clock $clock`
`--force_dat`	Forces an update of the project database with new delay information.
`--lower_priority`	Lowers the computing priority of the `quartus_sta` process.
`--post_map`	Uses the post-map database results.
`--sdc=<SDC file>`	Specifies the `.sdc` file to use.
`--report_script=<custom script>`	Specifies a custom report script to call.
`--speed=<value>`	Specifies the device speed grade used for timing analysis.
`-f <argument file>`	Specifies a file containing additional command-line arguments.
`-c <revision name> | --rev=<revision_name>`	Specifies which revision and its associated Quartus Prime Settings File (`.qsf`) to use.
`--multicorner`	Specifies that the Timing Analyzer generates all slack summary reports for both slow- and fast-corners.
`--multicorner[=on|off]`	Turns off multicorner timing analysis.
`--voltage=<value_in_mV>`	Specifies the device voltage, in mV used for timing analysis.
`--temperature=<value_in_C>`	Specifies the device temperature in degrees Celsius, used for timing analysis.
`--parallel [=<num_processors>]`	Specifies the number of computer processors to use on a multiprocessor system.
`--mode=implement|finalize`	Regulates whether Timing Analyzer performs a reduced-corner analysis for intermediate operations (`implement`),or a four-corner analysis for final Fitter optimization and placement (`finalize`).

2.6.2. The quartus_staw Executable

The `quartus_staw` executable opens a graphical interface to perform interactive timing reporting and analysis of your Quartus Prime project. The following methods are available:

- To run the Timing Analyzer as a stand-alone GUI application, type the following at the command prompt:

```
quartus_staw
```

`quartus_staw` can automatically open a project in the Timing Analyzer GUI if you specify the project name as an argument, as the following example shows. Specifying a project name as an argument saves you time because you do not have to browse to your project file after the GUI opens.

```
quartus_staw <project name>
```

You can specify a Tcl script that contains timing reporting and analysis commands to automatically run each time you open a project in the Timing Analyzer GUI. This feature allows you to easily define a uniform set of reports that the Timing Analyzer

GUI always generates, saving you time when you open a new project for interactive timing reporting. Use the `--report_script` option and specify a path to your report script:

```
quartus_staw --report_script=<custom script>
```

You must include only reporting and analysis commands in your report script. Do not include Tcl commands that open or close projects, create the timing netlist, read `.sdc` files, or update the timing netlist. The report script runs after the Timing Analyzer completely prepares the timing netlist for analysis.

You can optionally specify the directory and file names for the output of the reporting and analysis commands. The output of the reporting commands in the script are visible in the Timing Analyzer GUI, in the folder names you specify, when the reporting script completes. At that point, you can perform other reporting or analysis, as necessary.

2.6.3. Collection Commands

The Timing Analyzer supports collection commands that provide easy access to ports, pins, cells, or nodes in the design. Use collection commands with any constraints or Tcl commands specified in the Timing Analyzer.

Table 40. Collection Commands

Command	Collection Returned
`all_clocks`	All clocks in the design
`all_inputs`	All input ports in the design.
`all_outputs`	All output ports in the design.
`all_registers`	All registers in the design.
`get_cells`	Cells in the design. All cell names in the collection match the specified pattern. Wildcards can be used to select multiple cells at the same time.
`get_clocks`	Lists clocks in the design. When used as an argument to another command, such as the `-from` or `-to` of `set_multicycle_path`, each node in the clock represents all nodes clocked by the clocks in the collection. The default uses the specific node (even if the node is a clock) as the target of a command. The `-of_objects` option takes a node like a register and returns the clocks that drive it.
`get_nets`	Nets in the design. All net names in the collection match the specified pattern. You can use wildcards to select multiple nets at the same time.
`get_pins`	Pins in the design. All pin names in the collection match the specified pattern. You can use wildcards to select multiple pins at the same time.
`get_ports`	All ports (design inputs and outputs) in the design.
`get_registers`	Gets the specified registers in the design.
`get_keepers`	Gets the specified keepers in the design. Keepers are I/O ports or registers.

You can also examine collections and experiment with collections using wildcards in the Timing Analyzer by clicking **Name Finder** from the **View** menu.

2.6.3.1. Wildcard Characters

To apply constraints to many nodes in a design, use the "*" and "?" wildcard characters. The "*" wildcard character matches any string; the "?" wildcard character matches any single character.

If you apply a constraint to node `reg*`, the Timing Analyzer searches for and applies the constraint to all design nodes that match the prefix `reg` with any number of following characters, such as `reg`, `reg1`, `reg[2]`, `regbank`, and `reg12bank`.

If you apply a constraint to a node specified as `reg?`, the Timing Analyzer searches and applies the constraint to all design nodes that match the prefix `reg` and any single character following; for example, `reg1`, `rega`, and `reg4`.

2.6.3.2. Adding and Removing Collection Items

Wildcards that you use with collection commands define collection items that the command identifies. For example, if a design contains registers with the name `src0`, `src1`, `src2`, and `dst0`, the collection command `[get_registers src*]` identifies registers `src0`, `src1`, and `src2`, but not register `dst0`. To identify register `dst0`, you must use an additional command, `[get_registers dst*]`. To include `dst0`, you can also specify a collection command `[get_registers {src* dst*}]`.

To modify collections, use the `add_to_collection` and `remove_from_collection` commands. The `add_to_collection` command allows you to add additional items to an existing collection.

add_to_collection Command

add_to_collection *<first collection> <second collection>*

Note: The `add_to_collection` command creates a new collection that is the union of the two collections you specify.

The `remove_from_collection` command allows you to remove items from an existing collection.

remove_from_collection Command

remove_from_collection *<first collection> <second collection>*

The following example shows use of `add_to_collection` to add items to a collection.

Adding Items to a Collection

```
#Setting up initial collection of registers
set regs1 [get_registers a*]
#Setting up initial collection of keepers
set kprs1 [get_keepers b*]
#Creating a new set of registers of $regs1 and $kprs1
set regs_union [add_to_collection $kprs1 $regs1]
#OR
#Creating a new set of registers of $regs1 and b*
#Note that the new collection appends only registers with name b*
# not all keepers
set regs_union [add_to_collection $regs1 b*]
```

In the Quartus Prime software, keepers are I/O ports or registers. An `.sdc` file that includes `get_keepers` is incompatible with third-party timing analysis flows.

- remove_from_collection Command, Quartus Prime Help

2.6.3.3. Query of Collections

You can display the contents of a collection with the `query_collection` command. Use the `-report_format` option to return the contents in a format of one element per line. The `-list_format` option returns the contents in a Tcl list.

```
query_collection -report_format -all $regs_union
```

Use the `get_collection_size` command to return the number of items the collection contains. If your collection is in a variable with the name `col`, use `set num_items [get_collection_size $col]` rather than `set num_items [llength [query_collection -list_format $col]]` for more efficiency.

2.6.3.4. Using the get_pins Command

The `get_pins` command supports options that control the matching behavior of the wildcard character (*). Depending on the combination of options you use, you can make the wildcard character (*) respect or ignore individual levels of hierarchy. The pipe character (|) indicates levels of hierarchy. By default, the wildcard character (*) matches only a single level of hierarchy.

These examples filter the following node and pin names to illustrate function:

- `lvl` (a hierarchy level with the name `lvl`)
- `lvl|dataa` (an input pin in the instance `lvl`)
- `lvl|datab` (an input pin in the instance `lvl`)
- `lvl|cnod` (a combinational node with the name `cnod` in the `lvl` instance)
- `lvl|cnod|datac` (an input pin to the combinational node with the name `cnod`)
- `lvl|cnod|datad` (an input pin to the combinational node `cnod`)

Table 41. Sample Search Strings and Search Results

Search String	Search Result
`get_pins *|dataa`	`lvl|dataa`
`get_pins *|datac`	*<empty>*[6]
`get_pins *|*|datac`	`lvl|cnod|datac`
`get_pins lvl*|*`	`lvl|dataa, lvl|datab`

continued...

(6) The search result is *<empty>* because the wildcard character (*) does not match more than one hierarchy level, that a pipe character (|) indicates, by default. This command matches any pin with the name `datac` in instances at the top level of the design.

Search String	Search Result
`get_pins -hierarchical *|*|datac`	*<empty>*[6]
`get_pins -hierarchical lvl|*`	`lvl|dataa, lvl|datab`
`get_pins -hierarchical *|datac`	`lvl|cnod|datac`
`get_pins -hierarchical lvl|*|datac`	*<empty>*[6]
`get_pins -compatibility_mode *|datac`	`lvl|cnod|datac` [7]
`get_pins -compatibility_mode *|*|datac`	`lvl|cnod|datac`

The default method separates hierarchy levels of instances from nodes and pins with the pipe character (|). A match occurs when the levels of hierarchy match, and the string values including wildcards match the instance or pin names. For example, the command `get_pins <instance_name>|*|datac` returns all the `datac` pins for registers in a given instance. However, the command `get_pins *|datac` returns an empty collection because the levels of hierarchy do not match.

Use the `-hierarchical` matching scheme to return a collection of cells or pins in all hierarchies of your design.

For example, the command `get_pins -hierarchical *|datac` returns all the `datac` pins for all registers in your design. However, the command `get_pins -hierarchical *|*|datac` returns an empty collection because more than one pipe character (|) is not supported.

The `-compatibility_mode` option returns collections matching wildcard strings through any number of hierarchy levels. For example, an asterisk can match a pipe character when using `-compatibility_mode`.

2.7. Using the Quartus Prime Timing Analyzer Document Revision History

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Added new *Using Timing Constraints throughout the Design Flow* topic. • Revised the *Step 1: Specify General Timing Analyzer Settings* topic to add link to SDC-on-RTL info. • Revised *Step 3: Run the Timing Analyzer* topic for Early Timing Analysis and SDC-on-RTL. • Revised *Applying Timing Constraints* section for Early Timing Analysis and SDC-on-RTL. • Revised *SDC File Precedence* topic for SDC-on-RTL. • Revised *Iteratively Modifying Constraints* topic for SDC-on-RTL. • Added new *Using Entity-based SDC-on-RTL Constraints* section. • Revised *Using Entity-bound SDC Files* section for SDC-on-RTL. • Renamed *Generate Timing Reports* topic to *Timing Report Descriptions* and relocated.

continued...

[7] When you use `-compatibility_mode`, the Timing Analyzer does not treat pipe characters (|) as special characters when you use the characters with wildcards.

Document Version	Quartus Prime Version	Changes
		• Revised the *Timing Report Descriptions* topic to reference quartus_staw method. • Revised *Report Timing By Source File* topic to mention ability to open the source file in a text editor from the report. • Revised *Report Metastability* topic to mention ability to run Report Neighbor Paths, default toggle rate, and more report details. • Revised *Report Route Net of Interest* topic to mention ability to run report_timing from the report. • Revised *Timing Analyzer Scripting* topic to reference quartus_sta and quartus_staw executables. • Added more details about derived_clock naming to *Automatic Clock Detection and Constraint Creation* topic. • Added new *The quartus_staw Executable* topic. • Enhanced *Using Fitter Overconstraints* topic for details specific to the Hyperflex architecture, new examples, and *Other Overconstraint Combinations* table of examples. • Added new *Report SDC* topic explaining report and Comments column. • Revised constraint precendence in *Maximum Skew* topic.
2023.12.04	23.4	• Revised the *Applying Timing Constraints* topic to add introductory information and context about typical constraints. • Added new *Check Timing* topic describing Check Timing command and report. • Added new cross-referencing links throughout *Applying Timing Constraints* section.
2023.10.02	23.3	• Updated compilation dashboard image in *Step 3: Run the Timing Analyzer*. • Revised the following topics entirely: — *Using Entity-bound SDC Files* — *Entity-bound Constraint Scope* — *Entity-bound Constraint Examples*
2023.08.03	23.1	• Corrected typo in command example in *Report Data Delay* topic. • Corrected typo in command example in *Constraining CDC Paths* topic. • Corrected typo in command example in *Maximum Skew* topic. • Added *Promoting Critical Warnings to Errors* topic.
2023.04.03	23.1	• Revised updated image and description in *Report Register Description* for new Without a Control Signal and Synchronous Load columns and data.
2023.01.31	22.4	• Revised outdated timing model descriptions in *Setting the Operating Conditions for Timing Analysis* topic.
2022.09.26	22.3	• Renamed the report title "Report Reset Statistics" as "Report Register Statistics." • Revised the *Report Register Statistics* topic to describe some new features of the report. • Revised *Report Fmax Summary* topic to refer to get_clock_fmax_info command and provide more detail. • Revised *Example SDC Constraints for External Clock Mux* to replace logically_exclusive with physically_exclusive.
2022.03.28	22.1	• Described new Clock Network Viewer in *Report Clocks and Clock Networks* topic. • Updated *Report Register Spread* topic for new angle and area spread types and -to_clock filtering. • Added new *Report Timing By Source Files* topic. • Added new *Report Metastability* topic. • Added new *Report Bottlenecks* topic.

continued...

Document Version	Quartus Prime Version	Changes
		• Added new *Specifying Custom Bottleneck Criteria* topic. • Revised Basic .sdc Constraints Example in *Example Circuit and SDC File* topic. • Added more detailed constraint example and diagram to *Set Clock Groups* topic. • Revised scripting examples and screenshots in *Correlating Constraints to the Timing Report* topic. • Revised scripting example in *Creating Base Clocks* topic. • Revised scripting example in *Clock Divider Example* topic. • Revised *Constraining CDC Paths* topic. • Added note about referenced SDCs within IP to *SDC File Precedence* topic.
2021.09.27	21.3	• Updated name of Report Hierarchical Retiming Restrictions command and report to Report Retiming Restrictions. • Added *Constraining CDC Paths* topic and linked to related topics. • Updated *Setting the Operating Conditions* with details about operating condition nomenclature. • Replaced Custom Reports, Device Specific, Diagnostic, and Slack report folder names throughout. • Added *Report Exceptions and Exceptions Reachability* topic describing new report. • Added *Report Clocks and Clock Networks* topic describing new report. • Added *Report Data Delay* topic describing report. • Mentioned option to view multiple before and after paths in *Report Neighbor Paths* topic. • Added `set_clock_groups` to *Timing Exception Precedence* • Updated content of Extra Info tab in *Report Timing* topic. • Corrected the *set_clock_groups -group A -group B* table in the *Creating Clock Groups* topic. • Removed *Report Custom CDC Viewer Command* topic. • Revised assignment examples in *Exclusive Clock Groups* topic.
